Thus it will be seen that sixteen spaces or subdivisions in each individual target could easily and clearly be indicated to the gunners by the telegrams of the observatory department. Now, let it be borne in mind that an exact copy of the range net of each individual gun is in possession of the gunners, and that from previous careful practice the corresponding angle at which the gun has to be fixed in order to hit any one of the subdivisions has been determined, and is recorded in carefully-prepared tables of aim lines, so that in calm weather there is every chance of hitting the exact spot that may be indicated, even if the said spot be not visible. But before proceeding on the subject of the tables of aim lines, permit me a few remarks on the mounting of the guns. Already, in a former letter, I mentioned that the guns should be mounted somewhat like a theodolite on a large scale; thus the turntable or the parts by means of which the gun is turned (trained) from right to left, and *vice versa*, may be graduated in conformity with the radial subdivisions of the respective range; while correspondingly vertical arcs may be in connection with the trunnions or other parts of the body of the gun; but in order to insure very exact firing, it would be desirable to have the arrangements by which the exact horizontal and vertical angle of each aim-line is to be given to the gun, should be independent of the effects of the recoil, &c., of the gun; and the horizontal goniometer might hence be contrived either on the floor, or the roof, or the rear part of the place where the gun is situated, and the vertical goniometer on either one or the other, or both sides, the gun after each discharge having to be carefully placed into the exact fixed position in which its elevation, &c., could be determined to a nicety by reference to the goniometers and the exact lines and other marks contrived for that purpose on the body of the gun. As already stated, in calm weather, thanks to previous constant practice and its carefully recorded results, there is every chance of our guns hitting the exact spots we desire them to hit; but during windy and rainy weather it will be far more difficult to do so.

Being a mere "outsider," I would not venture to say whether it should be left to the judgment of the gunners to make such allowance in taking their aim as the direction and force of the wind should appear to them to require (in the which case a wind table would be in connection, or form certain columns in the aim-line tables), or whether said modifications in the aims had not better be controlled by the scientific department which is in charge of that branch of the defending forces. Certainly the latter plan would appear the simpler and hence more effective, as will be seen by the following example. Say the wind blows in the direction of the arrow W in the accompanying diagram, and we desire to hit the spot marked Q 6 *f.* (target Q 6 front). If, now, it be left to the gunners to fix their aim line so as to make allowance for the pressure and direction of the wind, it will, even with the best constructed tables, give them some trouble and cause delay, besides rendering it necessary that in each battery there should be dials, connected by means of wires with the central apparatus, for indicating the direction and measuring the pressure of the wind, so that the exact direction and degree of force of the wind could be seen. If, however, that matter is taken in hand by the proper scientific department, it is far more probable that very small, if any, errors would be made in order to adjust the aim-line so as to cause the projectile, exposed as it is to the influence of the wind, to hit the desired spot. By this means the accustomed mode of aiming the guns by reference to the simple aim lines would not at all be interrupted; for, if we wish to hit the spot Q 6 *f.*, but find out that in order to hit said spot with that particular gun of that particular range net we have to point our gun at the spot Q 5 *l.* (target Q 5 left), then we simply order the gunners to point their gun Q 5 *l.*, the—by us—carefully ascertained influence of the wind carrying the projectile so far to the right that it hits Q 6 *f.*, and thus our gunners could work away without need to care for wind or weather.

It will not be difficult to perceive that the department or departments in charge of regulating the fire of our guns should have in their possession also carefully-made topographical plans, comprising the areas of the range nets of all the guns of that section of the works which is under their charge; in the which plan obviously the range nets of various guns would necessarily overlap each other, so that, for example, if it is wished to bring the fire (say) of four guns to bear upon a certain spot in front, the orders would be to say—No. I. gun, P 4 *f.*; to No. II. gun, N 3 *x.*; to No. III. gun, O 1 *l.*; and to No. IV. gun, Q 5 *r*, the range nets of the four guns overlapping each other at such angles that the spots of the targets above mentioned coincide or cover each other. It might hence appear advisable that in the above alluded-to plan, the lines marking the different range nets should be drawn in different colours. There are various circumstances under which the above-indicated mode of guiding the fire of our guns would prove very advantageous to the defenders. At night, for instance, the trained look-outs of our observatories may, with the aid of their good instruments, discover certain hostile movements that would escape the men in the batteries; or at daytime a heavy fog or mist may cover the surrounding ground and sea, while, from our high armour-plated towers, the ground beyond or parts of approaching ships above the stratum of vapour may be visible; or the space immediately in front of some of our batteries may be covered with an artificial dense smoke caused by ourselves for certain purposes, &c. Still, in any of these cases we should be enabled to bring the fire of our guns promptly to bear upon the enemy, even though the spots or objects fired at may be invisible to our gunners.—

I am, Sir, yours, &c. G. J. GÜNTHER.

London, April 4.

Meetings for the Week.

MON.—Royal United Service Institution.—Captain T. R. Heathorn, R.N., R.A., on "A Muzzle-pivoting Gun-carriage on the Lever and Fulcrum Principle," at 8.30 p.m.

Society of Engineers.—Discussion on the paper by Sydney A. Reade, M.A., on "The Sewerage Works at Redhill," at 7.30 p.m.

TUES.—The Institution of Civil Engineers.—1. Mr. Allan Wilson, M.I.C.E., on "Irrigation in India"; 2. Mr. Thomas Login on "The Benefits of Irrigation in India, and on the Proper Construction of Irrigating Canals"; 3. Mr. George Higgin, M.I.C.E., on "Irrigation in Spain, Chiefly in Reference to the Construction of the Henares and the Esla Canals in that Country," at 8 p.m.

Royal Institution.—Dr. M. Foster on "The Development of Animals," at 3 p.m.

THURS. — Royal Institution. — Professor Odling on "Chemical Combination," at 3 p.m.

FRI.—Royal Institution.—Dr. Gladstone on "Some New Experiments on Light," at 8 p.m.

Royal United Service Institution. — Commander Frederick Warren, R.N., on "Cooking for Troops," at 3 p.m. Mons. Johan Sorensen will exhibit his Norwegian Self-acting Cooking Apparatus.

SAT. — Royal Institution. — Professor Odling on "Chemical Combination," at 3 p.m.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

A SUBSCRIBER will find his enquiry respecting condensed peat answered by a short article in another column.

RECEIVED.—J. R.—W. L. W.—T. E. C.—R. T.—C. C.—Messrs. K. and K.—T. W. T.—W. T. C.—J. W.—G. E. P.—R. J.—C. W. M.—R. M.—E. S.—R. F.—B. S.—H. H.—E. O.—S. K. M.—J. R.—T. C.—R. S.—A. J.—H. M. T.—S. A.—W. H. H.—G. W. H.—E. F.—R. S.—J. N.—J. T.—B. F. N.—R. J.—L. A.

Naval, Military, and Gunnery Items.

THE vessels employed in the Indian seas in connection with the Abyssinian Expedition now number 261, the total monthly expenditure for freight, exclusive of coal, being £413,000.

WE hear that the whole of the high-pressure twin-screw steam launches constructed and fitting at Chatham Dockyard are in future to mount a single rifle gun, which will be carried in the bow.

IT has been resolved by the directors of the Royal Mail Steam Packet Company to recommend to the proprietors, at the meeting to be held on the 29th inst., the payment of a dividend of £1 per share, free of income tax, for the half-year ending the 31st December last.

ACCORDING to report Messrs. Dudgeon have been selected to construct two Monitors for the defence of Bombay harbour, as their designs, price, &c., have met with the approbation of the Council for India, and recommendation of the Constructive Department of the Admiralty, at Whitehall.

ONE of the greatest continuous marches ever made by U. S. troops was made by Colonel Kearney's command in 1845, in his expedition to the Rocky Mountains, when his men marched twenty-five hundred miles in ninety-nine days, including all delays as well as time lost in councils with the Indians.

THE "Nymph," a composite screw of 810 tons gross register, and 100-horse power nominal, the second of two steamers intended for the China trade—built by Messrs. C. Connell and Co., and engined by Messrs. J. Howden and Co.—has made a trial trip, in which she attained a speed of 10¼ knots per hour, or one knot above the contract speed.

ON Saturday afternoon Robert Kidnard, one of the divers engaged at the wreck of the Greek vessel Boubolina, which it will be remembered blew up in the Mersey in November last, found the body of a man in a very decomposed state. The body has not yet been recognised, but it is supposed to be that of one of the crew of that vessel.

ABOUT two months ago the Prussian frigate, "Frederich Carl," then completed at La Seyne, near Toulon, lost her iron masts on the trial trip to England. The Prussian Government wished a commission of English naval officers to decide whether the shipbuilder was not by his contract bound to furnish new masts gratis, but we understand that the English Government declined to interfere.

THE guns ordinarily used for the equipment of Prussian men-of-war having at a recent experiment failed to make any great impression upon a 7-inch iron-plate target will be probably superseded by cannon of heavier calibre. The target consisted of 4½-inch soft iron, with a steel cover 2½-inch thick; the heaviest gun tried was a 9-inch breech-loader, made on the Prussian system.

A NEW engine of war is said to have been tried last week at Meudon, and has been found to exceed in rapidity and power of destruction even that secret gun of the private trials of which by the Emperor we have heard so much. The trial was strictly private, but a general officer who was present remarked that it was the most wonderful weapon he ever saw; and with it a battle would now last about half-an-hour.

MESSRS. W. DENNY AND BROTHERS, of Dumbarton, have launched two screw gunboats, built by them for the Viceroy of Canton, and named the "Kwang Tung" and the "Shang Tung." The vessels were launched with their engines and boilers on board. They are built on the composite system, with iron frames and wooden planking. The engines are of 70-horse power nominal, and the armament of each boat is to consist of one 70-pounder Armstrong gun amidships, two 20-pounder Armstrong bow and stern chasers, and four 6 and 12-pounder brass howitzers on the broadside.

TRIALS have recently taken place in Prussia with an assortment of breech-loading rifles from every country, the object being to ascertain their merits as compared with the needle-gun. Of the weapons tested, two—it is not said which—were found to admit of firing from one to two rounds more in a minute than the Prussian arm. This result, though counterbalanced by certain disadvantages, said to have been discovered in the foreign rifles, has led to the appointment of a commission charged with perfecting the needle-gun to the highest pitch known. It is thought that this object will be obtained by a simplification of the lock.

Miscellanea.

THE heat which the earth receives from the sun does not penetrate more than from 50ft. to 100ft. At Paris this stratum of invariable temperature is found at a depth of 86ft.

POUILLET has made observations with a pyrelio-meter from which he estimates that the amount of heat annually received by the earth from the sun would melt a crust of ice surrounding the earth 101ft. thick.

THE proprietor of the "Philadelphia Public Ledger" has erected new premises for that journal containing 64,812 square feet of space, and lighted by 354 windows. To pass round all the above-ground apartments constitutes a journey of 1,798 yards, or rather more than a mile.

THE administration of telegraphic lines has issued a notice that of the five submarine cables which connect France and Belgium with England, four have been ruptured by a tempest. The only one that remains in working order is that which starts from Dieppe.

THE anniversary dinner of the Horological Institute of Great Britain will be held at the Guildhall Tavern, on the 19th of May; the Right Hon. the Lord Mayor has consented to preside. We would urge on the members the importance of a full attendance on the occasion.

THE Suez Canal Company has for more than a year been conveying merchandise and passengers between the two seas. The receipts from this service have gone on steadily increasing; they were, in January, 1867, 47,664f., and during the corresponding month of the present year, 197,317f.

THE Steam Man which has furnished a number of paragraphs for the press, is on exhibition at 538, Broadway, New York, nearly opposite the site of Barnum's Museum; but owing to some objection on the part of the owner of the hall, he is not permitted to "travel on his muscle," but is hung in slings and merely marks time.

IN consequence of the immense number of visitors on Easter Monday and Easter Tuesday, who viewed the Houses of Parliament, far exceeding those in the Exhibition year, it is understood that the Lord Great Chamberlain has decided that the "Houses" shall be open to the public on Whit Monday and Tuesday.

AN important conference of railway shareholders was opened on Tuesday in the Town Hall, Manchester, to take into consideration the most desirable course of management to be adopted by railway companies in the future. Mr. Thos. Bazley, M.P., presided. There were about 160 shareholders present.

THE obituary of "The Times" of the 8th inst. contained some rare illustrations of prolonged existence in five ladies and two gentlemen, whose united ages amounted to 603 years, giving an average of upwards of 86 years and one month to each; of the ladies the oldest had reached the great age of 93 years, and the youngest 82; of the opposite sex, one was 89 and the other 82 years of age.

M. ALVERGNIAT, of Paris, has constructed a new apparatus for proving that electricity cannot pass through an absolute vacuum. Two platinum wires are inserted into a tube so that their free ends are within about an eighth of an inch of each other. The air is then exhausted from the tube by means of a mercurial column, after which the electric spark will not pass from one platinum wire to the other.

THE visitors to the South Kensington Museum during the week ending April 11 were—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 11,280; on Wednesday and Thursday, (admission 6d), from 10 a.m. till 6 p.m. 1,366. National Portrait Exhibition, by payment, 2,616; Total—15,262. Average of corresponding week in former years, 11,501; total from the opening of the Museum, 7,294,633.

IT is proposed to establish an exhibition of living insects in the new public garden which is being formed at Montsouris, in the outskirts of Paris, and M. Hamet, professor of agriculture at the Luxemburg, is directed to draw up a report on the subject for the municipal council. Without taking into account the parasitic creatures that could not conveniently be exhibited alive, there are more than 20,000 species and varieties in the insect world.

THE only rolling mill at Wisconsin is that of the Milwaukee Iron Company at Milwaukee. It was projected about one year ago, and is now nearly ready for work. The main building is 211ft. by 180ft, and is without supporting inside pillars. It contains seven combined furnaces. The engine which drives the machinery is of 1,000-horse power, the fly-wheel of which weighs thirty tons and is 32ft. in diameter.

THE resistless power of frozen water is illustrated in a lecture on heat and cold, delivered by Professor Tyndall before the Royal Institution of Great Britain. Among his experiments, an ordinary bombshell was filled with water, and securely plugged, and then placed in a bucket filled with pounded ice and salt, to freeze it. In about half an hour the bombshell was burst into fragments by freezing of the combined water.

THE Jean of Arc Tower at Compiegne fell down on Saturday week, and the crash caused great terror in the quarter of the Rue Jeanne d'Arc. There was no loss of life; but a little girl, the daughter of a wineshop keeper named Gruing, escaped death by a marvellous accident. Owing to a temporary illness she was taken out of her bed a short time before the accident occurred to sleep with her parents in another part of their house. When the tower fell the bed which the child had recently quitted was smashed into atoms.

A COMMUNICATION from Moscow gives an account of the trial of the Borodino Bridge just terminated over the Moskowa river. The water butts of the fire brigade, all filled, and sixty carts laden with sand, weighing together about 100 tons, were brought on the structure, after which the people who had assembled on the banks were naively invited to stand also in the centre. The bridge was fortunately proof against this foolish experiment, for had any accident occurred the consequences would have been terrible.

THE Paris Numismatic and Archæological Society has inaugurated its fourth year of existence by the opening of more spacious rooms for its conferences, collections, and library, at No. 58, Rue de l'Universite. In addition to some interesting publications, this comparatively new society has established weekly conferences; and it is divided into sections for the study of inscriptions, historic geography, and the history of ceramic art. It was commenced by the Vicompte de Ponton d'Amecourt and eleven other gentlemen, and now numbers 120 members and 220 correspondents.

FOUR parts by weight of yolk of egg rubbed in a mortar with five parts of glycerine, according to the Philadelphia "Journal of Pharmacy," gives a preparation of great value as an unguent for application to broken surfaces of the skin of all kinds. The compound has a horny-like consistency, in unctuous-like fatty substances, but over which it has the advantage of being quickly removed by water. It is unalterable, a specimen having laid exposed to the air for three years unchanged. Applied to the skin it forms a varnish which effectually excludes the air, and prevents its irritating effects.

THE "Opinione" of Florence announces that the Italian Government have come to an understanding with the administration of the railway companies, to allow travellers entering Italy at Susa, and leaving it at Ancona or Brindisi to have their luggage conveyed *in transit*, without submitting them to any examination of the Custom-houses, either on coming in or going out. The main object of this measure is to avoid any stoppage or delay to travellers on their way to India, who, even before the completion of the Mont Cenis Tunnel, might wish to embark at Brindisi rather than at Marseilles.

TWO public works belonging to the highest grade of modern civilization are going on at Athens—a telegraph line to Kephisia, and a railway to the Piræus whence the people of the capital draw every article of consumption. The railway is only six miles: all the earthwork and about half the bridging are finished, and if the rails arrive soon, the company can easily complete the line before the end of August, which is the term fixed by the contract for opening the railway. This railway is much wanted, and will doubtless prove a profitable undertaking.

AN electrical clock in the rotunda of the Philadelphia Merchants' Exchange has a running gear of the simplest description, consisting merely of two cog-wheels and a ratchet-wheel. The driving power is supplied by a weak galvanic battery, the currents from which, transmitted through two galvanometer coils placed one on each side of the clock-case, act upon steel bar magnets set within the pendulum-ball. The latter swings between the two coils, so that when one of them is "positively charged" the ball is attracted until by contact it becomes similarly electrified, and consequently repelled, then swinging over to the "negative" coil, it becomes negatively charged, again repelled, and thus the vibrations are kept up indefinitely, or as long as the battery continues working. The alternate positive and negative charges are made and broken by a simple slide bar moved by a wire pin on the pendulum rod.

THE prospectus has appeared of the Indo-European Telegraph Company (Limited), with a proposed capital of £450,000, in shares of £25 each, of which only 17,000 will now be issued. The object is to establish a direct and independent line of telegraphic communication overland between England and India. The new line will also connect Europe with Asia, passing from London through the North Sea, Prussia, Southern Russia, and Persia, and thence by the lines of the Indian Government to India. An agreement, it is stated, has been concluded by the concessionaires with Reuter's eTlegram Company, and the Electric and International Telegraph Company, for the exclusive use of one wire, and when necessary two wires, between London and Norderney. A submarine cable of about 200 miles will be laid in the Black Sea, in order to avoid the Circassian mountains, where the existing lines are subject to interruption by snow. By the terms of the tender the line is to be completed within the year 1869.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—2674, 2679, 2689, 2722, 2745, 2752, 2757

BUILDINGS AND BUILDING MATERIALS—2677, 2712, 2729

CHEMISTRY AND PHOTOGRAPHY—2678, 2680, 2685, 2711, 2721, 2731, 2736

CULTIVATION OF THE SOIL, including agricultural implements and machines—2697, 2702

ELECTRICAL APPARATUS—None.

FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2690, 2706, 2710, 2724, 2727, 2738, 2747, 2754, 2758

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—2753

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—2723

GENERAL MACHINERY—2675, 2676, 2687, 2688, 2705, 2716, 2718, 2720, 2728, 2732, 2733, 2744

LIGHTING, HEATING, AND VENTILATING—2701, 2708, 2741

METALS, including apparatus for their manufacture—2704

MISCELLANEOUS—2681, 2683, 2691, 2692, 2693, 2694, 2696, 2698, 2699, 2700, 2703, 2707, 2709, 2714, 2715, 2719, 2726, 2734, 2735, 2737, 2742, 2746, 2749, 2750, 2751

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2684, 2730, 2739, 2740, 2755

SHIPS AND BOATS, including their fittings—2748

STEAM ENGINES—2682, 2713

WARFARE—2695, 2725, 2743

2675 J. GRIFFIN and F. GREEN. *Improved machinery or apparatus to be used in the manufacture of envelopes.* Dated September 23, 1867.

The first part of this invention relates to certain improvements in envelope folding machines on the rotary principle, and consists in making the cheeks straight instead of in an angular or irregular shape, and carrying the rollers on gun metal journals in slot holes in the cheeks; also increasing the back and front flaps of the envelope by causing the knife on the upper roller to make the crease on a small slit of india-rubber set in a groove in the under roller instead of on a band; also in a dishing piece which receives and folds the first flap after it has passed through the rollers above mentioned, and two pieces or guides of thin steel which hold down the envelope and keep it from puckering. It further consists in the use of a templet fixed so that the envelope may pass under it when it leaves the roller and creaser which has creased the end flaps; in two pieces of steel with bevelled edges which fold the end flaps over as they pass from the templet; and, finally, in a piece of metal fastened to a bar carried on the frame of the machine into a cavity in which piece of metal the envelope passes for the folding of the last flap, the envelope passing thence bottom upwards into a box the size of the envelope, and from which the envelopes are withdrawn by the bottom in regulated numbers. The envelope is gummed and stamped in passing through the creasing rollers, as in other machines on this principle, and by simply altering the adjustment of the parts of the machine it folds envelopes of different sizes. The second part of the invention relates to a novel apparatus for feeding envelope shapes into folding machines.—Patent completed.

2676 J. FLETCHER. *Improvements in steam or other power hammers.* Dated September 23, 1867.

This invention relates, first, to the hammers driven by a crank or cam shaft actuated by steam or other power, and consists in an improved mode of starting, stopping, and regulating the speed of the hammer by a lever upon a shaft having two cams, one of which applies a break to the fly-wheel, and the other throws the driving power out of gear, or shuts off the steam. The invention consists, second, in making the top or upper part of the hammer block hollow for the reception of two spiral springs acting above and below a disc or piston, which is connected by a link to the crank shaft driven by steam or other power. As the crank shaft revolves, the disc or piston, acting on the springs, raises and lowers the trip or hammer block, the force of the blow depending upon the weight of the trip or hammer block, and parts connected therewith, the speed of the crank shaft and the strength of the springs. Instead of springs, atmospheric air, or other elastic medium, may be employed.—Patent abandoned.

2677 W. COOKE. *Improvements in apparatus for the regulation of up and down currents of air.* Dated September 23, 1867.

This invention consists of an apparatus that effectually regulates the up and prevents the down draught in shafts or chimneys by the application of outer flanges or breaks to an upright tube or shaft open at both ends, having angular or other shaped openings in the sides, with inner tubes perpendicularly arranged, so as to direct the upward current of the air or smoke, permitting it freely to ascend, the whole apparatus acting as an exhauster of the air, facilitating the upward current, the openings at the sides serving as escapes for the downward current.—Patent abandoned.

2678 J. HARGREAVES. *Improvements in separating pyrites, shale, and other impurities, from coal.* Dated September 23, 1867.

Here the separation of impurities from coal is effected by the employment of a solution or liquid, called by the inventor the separating solution, of a density intermediate between the specific gravities of the coal and the impurities to be removed. When the impurities are of higher specific gravity than the coal, the separating solution is of such a density that the coal will float, whilst the impurities will sink to the bottom of the vessel containing the said separating solution; but when the impurities are lighter than the coal, then the separating solution is made of less density than the coal and heavier than the impurities, so that the coal will sink while the impurities will float. The separating solution can be obtained by mixing sulphate of soda, chloride of calcium, chloride of iron, or chloride of manganese in water, or by using any other salt or suitable agent or substance.—Patent abandoned.

2679 W. BEARDMORE, W. BROCK, and A. C. KIRK. *Improvements relating to furnaces.* Dated September 23, 1867.

This invention relates to a convenient means of regulating the internal condition of a reverberatory or similar furnace, in order to deprive its interior of free oxygen when desired, and consists in introducing into the interior of the furnace (at some convenient point over the fire, or between the fire and the object to be heated) materials having a strong affinity for oxygen, such as the various hydro-carbons, other products of the distillation of carbonaceous or organic substances, hydrogen, carbonic oxide, or any mixture thereof.—Patent abandoned.

2680 J. BLAIR. *Improvements in revivifying animal charcoal.* Dated September 23, 1867.

This invention consists in passing or forcing through the animal charcoal a suitable heated gas or mixture of gases. It is desirable for the gas or mixture of gases to contain as small a proportion as possible of free or unsaturated oxygen, or similar gas that would act injuriously on the animal charcoal.—Patent abandoned.

2681 R. WAPPENSTEIN and A. LAIDLAW. *Improvements in envelopes.* Dated September 23, 1867.

This invention consists in the addition to an ordinary envelope of a metallic ring or plate with indents or teeth bending upwards or downwards. This ring or plate is placed in or upon the envelope, and by means of pressure with the thumb or a stamp, the teeth are bent upwards or downwards, and thereby grasp the flaps or folds of the envelope, and secure it from being opened without detection.—Patent abandoned.

2682 L. R. BODMER. *Improvements in the construction of air cylinders of blast engines, and in the valve arrangements for the same.* (A communication.) Dated September 23, 1867.

This invention consists in the combined application of the elastic hoop, ring, or belt valve, with the flap valve, and in the peculiar construction and arrangement of the cylinder and its parts for this purpose, the object of the invention being to combine the advantages which the elastic belt valve possesses over other valves when used as suction valves with those possessed by the flap valve as pressure valves.—Patent abandoned.

2683 A. M. CLARK. *Improvements in boots and hoes.* (A communication.) Dated September 23, 1867.

This invention consists in fixing a metallic frame to the insoles of boots and shoes provided with mortises of the forms indicated for receiving pins or projections fixed on a separate sole, by which means the latter may be readily adjusted and fixed in position on the inner sole by a sliding movement without other aid.—Patent completed.

2684 S. BEVAN. *Improvements in apparatus for ventilating underground railways and other like structures.* Dated September 23, 1867.

Here the inventor mounts on a suitable truck or carriage, which may form part of a train, a fan or other suitable apparatus for introducing a current of fresh air into the underground railway, or other like structure to be ventilated. This is accomplished by the axis of the fan or other suitable ventilating apparatus being driven from the axles of the truck or carriage.—Patent abandoned.

2685 A. ZIEGELE. *Improvements in the manufacture of Epsom salts.* (A communication.) Dated September 23, 1867.

This invention consists in manufacturing Epsom salts from the kiserit contained in the Stassfurt and Duhalt Abraum salts; also from the refuse obtained in the manufacture of muriate of potash in the form of kiserit.—Patent completed.

2686 H. FORBES. *Improvements in the construction of rotary pumps.* Dated September 24, 1867.

The patentee claims, first, forming the outlet aperture of the pump casing as a narrow slit of equal width at all points, and with rounded ends, substantially as and for the purposes set forth. Second, forming the inlet aperture of the pump casing as a narrow slit of equal width at all points, substantially as and for the purposes set forth. Third, the employment of the dome described and shown in the drawings, for conducting the water from the long narrow outlet aperture of the pump casing to the circular discharge tube, as set forth.—Patent completed.

2687 W. WINTER. *Improvements in sewing machines.* Dated September 24, 1867.

This invention relates to means of working or operating the needles and shuttles or other thread carriers employed in sewing machines, and the improvements consist in the combination of a bell or boss cam with a plate cam on the same shaft, and in the application thereof to an arrangement of levers or other connecting parts for working the said needles or shuttles or other thread carriers of sewing machines.—Patent completed.

2688 G. BATCHELDOR. *Improvements in trough water-closets.* Dated September 24, 1867.

The object here is to provide trough water-closets at a less price with rounded surfaces, or surfaces sloping towards the outlet valve, and in part, that is to say, as regards the trough part, of non-absorbent and more durable materials than those now in use. For this purpose the patentee makes or constructs the troughs of earthen or stoneware, and in or over the soil pipe leading therefrom he fixes or forms a valve seating, the valve of which is connected to a lever or its equivalent, and is led into a locked-up space, the key of which is in the possession of a person whose duty it is to see that from time to time the trough is emptied and flushed. The seats are of the ordinary form.—Patent completed.

2689 J. LEWIS, W. HUNTINGTON, and W. ANYON. *Improvements in movable firebars.* Dated September 24, 1867.

Here the inventors construct a frame consisting of a dead plate, two side bars, and a bridge plate, which they bolt together, the whole of which is secured to the furnace front by bolts; on the inside of each side bar they screw or cast on three pedestals to carry three rocking shafts, one in the centre and one at each end; on the centre rocking shaft every alternate bar is fixed, which bars extend the whole length of the furnace; the other bars are made in two lengths, one of which is secured to each rocking shaft; the other ends meet in the centre, and rest when level on the centre rocking shaft. On the underside of each long bar is cast or fixed a stud halfway between the centre and the rocking shafts; the centre rocking shaft is moved by lever underneath to the front end of the furnace, and when moved the aforesaid studs projecting from the side of long bars and underneath the short bars lift the ends of the short bars, thus giving an alternate motion at each end to all the bars. The effect of these arrangements will be obvious.—Patent abandoned.

2690 J. H. BROWN. *Improvements in the manufacture of paper and articles of paper.* Dated September 24, 1867.

This invention has for its object the incorporation of animal substances with vegetable fibres in the production of paper, and thereby to give greater strength thereto. The patentee employs either skins, or refuse parts of the skins, of buffalo, bull, ox, cow, calf, or other animal substances from which glue and size are generally made.—Patent completed.

2691 P. H. COLOMB and F. J. BOLTON. *Improvements in the production of light and heat for signalling and other purposes.* Dated September 24, 1867.

This invention refers to the production of light and heat by the combustion of imflammable powders. The patentees use receptacles so constructed that the lower ends, mouths, or orifices of the tubes or passages by which the powder is conveyed or guided to the flames or heated surfaces for consumption, extend down to and are closed by the surface of the powder contained within the main bodies or casings of the receptacles.—Patent completed.

2692 T. H. WILLIAMS. *The improvement of gas burners.* Dated September 24, 1867.

This invention consists in the application to gas burners of a small metallic vertical disc or plate arranged above and across the centre of the nipple, the object being to divide the jet of gas and consequent flame, thereby increasing the light by causing a larger quantity of oxygen from the atmospheric air to mingle or combine with the gas and flame, and effecting complete combustion of the coal or other gas, and also preventing the rushing or humming noise so common in ordinary gas burners.—Patent completed.

2693 R. WILSON and J. NUTTALL. *Improvements in the manufacture of cranked axles, cranked shafts, and other heavy forgings.* Dated September 25, 1867.

The patentee claims piling together several layers of bars of iron lying at right angles or diagonally to each other to form a bloom for the manufacture of cranked axles, cranked shafts, and other heavy forgings.—Patent completed.

2694 C. D. ABEL. *A new or improved method and apparatus for converting the gaseous products of combustion into combustible gases.* (A communication.) Dated September 25, 1867.

This invention has for its object to utilize the waste heat of furnaces and fireplaces, and consists, mainly, in employing such heat to effect the regeneration of the gaseous products of combustion from the furnace or fireplace that is to convert such gases, which consist, mainly, of carbonic acid and vapour of water, into combustible gases, such as carbonic oxide and hydrogen.—Patent completed.

2695 J. C. BAYLEY and D. CAMPBELL. *Improvements in projectiles and their manufacture.* Dated September 25, 1867.

Here the inventors do not claim or confine themselves to any particular form or size of elongated projectile, but, by way of illustration, they refer to the present pattern used by the British Government for the Snider rifle, in which a parallel hole of about ¼in. deep is formed in the front of the projectile, and afterwards filled with wood, the object being to lighten the missile in front, and thereby to secure more accurate firing. The improvement consists in dispensing with the said wood, at the same time retaining all its advantages, thus considerably reducing the cost of manufacture. In forming the projectile, as claimed by the inventors, the hole is made as before stated, but, instead of filling it with wood, they leave a projection of metal at the front, which they afterwards close over the said hole, thus forming the point and leaving a cavity. They likewise arrange that the metal shall be so distributed as to compensate for the loss of weight by the extraction of the wood.—Patent abandoned.

2696 D. R. RATCLIFF. *Certain improvements in the manufacture of safes and other depositories.* Dated September 25, 1867.

This invention relates to the construction of safes, and other similar depositories, and is designed to render the corners or angles, where the sides of such chambers meet and are connected, stronger and better able to resist violence than hitherto. The improvements consist in the application and use of solid metallic bars for the angles (that is, at the extremities of each end and side of the safe), which bars are provided with deep grooves into which all the plates forming top, bottom, sides, and back fit and are embedded, and through certain parts of the length of each bar taper or wedge-like slots are formed, into and through which corresponding pieces of the side, top, bottom, and back plates enter, the plates being so cut as to leave these pieces projecting so as to enter the slots. The safe or chamber is constructed or put together by fitting the plates into the bars at each angle, and then hammering out or riveting the pieces of plate projecting through the wedge-like slots, so as to spread out or expand the said projecting pieces into dovetail form, and to fill the slots by the expansion of such pieces, whereby the sides are securely held together, and cannot be burst asunder without withdrawing all the dovetail pieces of the sides from the taper slots to the angle bars, which would require enormous force.—Patent abandoned.

2697 W. M'I. CRANSTON. *Improvements in implements for digging potatoes.* (A communicaiton.) Dated September 25, 1867.

This implement, which is in the nature of a plough, is constructed with a mould board so formed that the earth and roots together rise up on to a number of inclined fingers or prongs between which the earth in part passes, whilst the crop rising up falls off over their upper ends on to another set of fingers beneath. These fingers are more nearly horizontal, and form a grid which effects a further separation of the earth from the crop before the latter falls on the land in the track of the implement.—Patent abandoned.

2698 J. MUSGRAVE. *Improvements in fittings for cow*

Digitized by Google

houses, saddle-rooms, and stables, the ventilators of the latter being also suitable for other apartments. Dated September 25, 1867.

This invention is not described apart from the drawings. —Patent completed.

2699 A. TOD and J. HEATLEY. *Improvements in the manufacture of tobacco.* Dated September 25, 1867.

Here the tobacco in the prepared state for twisting is placed upon a table, at one end of which a revolving frame is situated, and through an opening in the end of the frame the tobacco to be twisted is entered. The revolving frame contains a bobbin upon which the tobacco as it is twisted is wound, a separate revolving motion perpendicular to the motion of the frame, being imparted to the bobbin by means of a cord or belt passing over a pulley in its axis, being led thence over a pair of pulleys and over a grooved ring concentric to the axis of revolution of the frame, so that as the frame revolves, the belt is by the motion of the frame caused to travel. When the bobbin is filled the machinery is stopped and the tobacco taken off, the machinery being provided with suitable engaging and disengaging gear, and driven by a belt actuating a pair of live and dead pulleys.—Patent completed.

2700 G. CLAYTON and W. MARBECK. *Improvements in water meters.* Dated September 25, 1867.

Here the inventors place upon a cylinder of small dimensions, say 2in. diameter, by 6¼ in length, a valve chest, having ports similar to those of an ordinary steam engine slide valve, that is to say, two inlet ports connected by the valve itself with an exhaust port. The valve is worked from a small transverse shaft passing through the admission chamber, and connected with it by catch levers attached on the outside to a bearing, having an angular toothed formation, and supported by small runners projecting from the side; they impart to a longitudinal shaft extending the whole length of the cylinder, and connected to force pistons working through the ends of the same, a reprocating motion; a water piston works freely within the cylinder. This latter piston is constructed of two metallic plates perforated and having a ferrule to keep them apart, whilst leathers are flanged outwards and secured in the centre of the piston, the flanges being kept tight against the cylinder by the water admitted through the perforations. The action is as follows:—The water is admitted alternately by each port, and by the alternate or reciporatory action of the pistons fixed in the ends of the cylinder, the water piston (so termed for distinction sake) accordingly forces out the water through the several ports, each stroke of course indicating a given amount of water, which is registered by any of the ordinary clock apparatus used for such indications.—Patent abandoned.

2701 W. WOODCOCK. *Improvements in apparatus for warming and ventilating buildings.* Dated September 25, 1867.

This invention, under one head, has reference to improvements applicable to stoves of the character of Gurney's stoves, or any stove having a number of plates from its outer surface, with the plates vertical in a trough of water, or any stove of analogous construction or action, and consists in constructing the said stoves with feeding door, fire door, and ash pit door, so arranged that they shall open into a stoking chamber or compartment, which is otherwise entirely separated from the stove, such stoking chamber or compartment being wholly separated from the building to be warmed and ventilated.—Patent completed.

2702 R. WAYGOOD. *Improvements in machines for cleaning rice and other grain or seed.* Dated September 25, 1867.

The object here is to construct machines to be worked by manual power, and the invention, mainly, consists in the combination (as described) of a disc and a wheel between which the rice, grain, or seed is fed, and by which it is cleaned.—Patent abandoned.

2703 A. ROOKER. *Improvements in taps for beer casks and other vessels.* Dated September 25, 1867.

The main object here is to do away with the necessity of driving in, by means of the tap itself, the cork or bung which closes the tap hole of beer casks, and the invention consists in so constructing the inner end of the tap that it will cut out a circular piece of the cork, or bung, and will at the same time close the aperture thereby formed in the cork or bung. In carrying out the invention the patentee constructs the inner end or portion of the tap tubular, and open at the inner extremity, and he forms this circular extremity with a cutting edge which is saw-toothed or serrated; or it may be a plain cutting edge.—Patent completed.

2704 J. BOWER. *Improvements in the manufacture of iron and steel.* Dated September 25, 1867.

This invention relates, chiefly, to the manufacture of malleable iron, and iron applicable for manufacturing into steel, and consists in purifying the iron as hereafter described, whereby the inventor obtains a strong fibrous metal. He takes, say, 4cwt. of cast iron, which he melts in a puddling furnace, and while it is in a fluid state he introduces and mixes with it about 2 per cent of chloride of aluminium, with a little carbonaceous matter, such as charcoal or sawdust, which he prefers to use in a moist state. The iron is then puddled in the usual manner.—Patent abandoned.

2705 A. M. CLARK. *An improved combined tuck creaser and self-guide or baster.* (A communication.) Dated September 25, 1867.

We cannot here give space to the details of this invention.—Patent abandoned.

2706 J. and J. KIRK. *Improvements in the manufacture of lace or wearings made on bobbin net or twist lace machines.* Dated September 25, 1867.

This invention consists in making the woven portion of each breadth by means of the warp threads alone, without the employment of bobbin threads intervening between the selvedges or edges of the woven portions of each breadth, but at each extremity or selvedge of such woven portion the patentees employ one or more bobbin threads to twist with the warp thread or threads, as in the ordinary way.—Patent completed.

2707 J. OXLEY. *Improvements in refrigerators for cooling worts and other liquids, which improvements are also applicable to condensers.* Dated September 26, 1867.

The patentee claims, first, the use of air and water together in refrigerators composed of separate flat tubes, with internal partitions contained in a case, such air and water being used in the manner and for the purpose described; and, second, the use of air and water together in condensers composed of separate cells or chambers, with internal partitions contained in a case, the tubes for the aeriform fluid passing through the cells or chambers, and being cooled by the water and air therein, as described.—Patent completed.

2708 G. H. J. SIMMONS. *Improvements in lamps for burning hydrocarbon and other oils.* Dated September 26, 1867.

This invention relates, first, to the receptacle for the oil being away from the burner, and for this purpose, for lamps with one burner, the patentee employs two tubes of different sizes, a smaller tube enclosed in a larger tube, the ends of such tubes being soldered, screwed, or otherwise fastened to the receptacle for the oil, and to a small chamber, attached to which is the burner; the smaller tube is longer than the larger tube on the end that is fastened to the receptacle for the oil, to allow of the atmosphere to escape while it is being supplied with oil; the ends of the tube attached to the small chamber are nearly level with each other, consequently the oil flows from the receptacle through the larger tube until it covers the opening of the smaller tube enclosed within it, preventing admittance of the atmosphere to the receptacle, and more oil flowing into the small chamber before mentioned than is required to supply the burner. Second, the improvements relate to lamps with more than one burner. Attached by means of a screw to the receptacle containing the oil are two tubes parallel to each other, the tubes are furnished with stopcock or piece of metal to slide over their opening, and enable the receptacle to be moved without the oil spilling; the ends of the tubes not attached to the receptacle are unequal in length, and are inserted into a small chamber, the effect of which is,—the oil flowing from the receptacle down the longer tube rises in the small chamber until it reaches the opening of the shorter tube, and, by preventing admittance of the atmosphere, the receptacle containing the oil keeps the oil at one level. Attached to the said chamber are pipes communicating to other small chambers, the bottoms of which are lined with wire gauze, and to which are attached the burners. The improvements also relate to the lamp first mentioned, the receptacle of which is flat on one side, and to the top of such flat side is attached a metal loop to permit of its being hung against a wall, and at bottom of such flat side is hinged a piece of wire or metal to admit of its being placed upon a table or other flat surface, and remaining upright.—Patent completed.

2709 J. A. SMYTH. *Improvements in cinder sifters.* Dated September 26, 1867.

The box or case of this cinder sifter consists of an oblong rectangular chamber supported on four legs. The box or case is surmounted by a hopper into which the cinders to be sifted are put. The bottom of the hopper opens over the top of the sieve, which is situated within the case. The sieve is supported upon a pivot near the middle of its underside, upon which pivot the sieve is capable of performing an oscillating motion. The said sieve is inclined, the end on which the cinders are received from the hopper being the highest point. Underneath the sieve is a drawer into which, when the sifter is in operation, the ash falls, and immediately under the bottom end of the sieve is an opening in the bottom of the box or case, from which opening, when the sifter is in operation, the cinders fall. In that end of the box or case at which the upper end of the sieve is situated is an axis workefi by a winch. The inner end of this axis carries a wheel with a series of large teeth or tappets. When the winch is turned the teeth or tappets strike against the upper end of the sieve, forcing it away from the axis. A spring connected with the end of the case and top of the sieve produces the return motion of the sieve. By turning the winch there is produced an oscillatory motion of the sieve upon its pivot. In using the cinder sifter, a scuttle of mixed cinders and ashes is put into the hopper, and the empty scuttle is placed under the before-mentioned hole in the bottom of the box or case. The winch is turned a few times, when the oscillatory motion given to the sieve causes the cinders to roll down the said sieve and fall from its lower end through the opening in the case into the empty scuttle, the ash at the same time passing through the meshes of the sieve into the drawer.—Patent abandoned.

2710 A. TAYLOR. *Improvements in weaving ornamental fabrics.* Dated September 26, 1867.

The patentee claims the producing of ornamentally spotted fabrics by weaving spotted chenille threads along with ordinary warps and wefts, and by means of heddles or healds, substantially as described.—Patent completed.

2711 R. W. BENNIE. *Improvements in the manufacture of moulders' blackening.* Dated September 26, 1867.

This invention consists in employing the following ingredients, namely, first, shale, or the earthy deposits left in retorts in the first distillatory process for obtaining crude shale or other mineral oils, or other spent bituminous substance; second, still bottoms, or the coke or carbonaceous deposit left in stills in distilling shale oils, petroleum, tar, or other mineral oils; third, blind coal or anthracite; fourth, gas coke; fifth, wood charcoal; and, sixth, fireclay.—Patent abandoned.

2712 J. SYME. *Improvements in supporting window sashes, shutters, doors, and other similar structures.* Dated September 26, 1867.

This invention consists in supporting window sashes by elastic rollers formed of india-rubber, gutta-percha, or compounds thereof, or other similar elastic substance affixed to the sash, and working against the frame in which the sash slides. The rollers are supported with capability of revolving in bearings affixed to the edge of the sash, and should be of such a diameter that, when the sash is in position, they may be slightly compressed by the frame in which the sash slides, and, by the friction obtained by such compression, hold the sash securely in any position required.—Patent abandoned.

2713 J., B., and R. WOOD. *Improvements in steam engines.* Dated September 26, 1867.

This invention consists of an arrangement of apparatus whereby the admission, cutting off, and release of steam is attained by distinct and separate means, and the arresting of the travel of the cut-off valve is effected before the admission valve arrives at the termination of its stroke, and in such manner as will not affect the set "lead" of admission. It will also admit of the full indicated steam pressure in the boiler being thrown on the piston at all times, and the varying loads or weights to be driven will cause the cut-off which is connected to, and actuated by, the governor, to act instantly, as may be required, according to the varying loads or weights thrown on and off, thereby effecting the utmost economy possible in the using of steam in proportion to the power exerted. The apparatus consists of a curved valve of similar construction to the valve commonly known as the "Corliss valve," having openings through it, and on the inside of which is another valve, also of similar configuration to the "Corliss valve," which is moved along with the main or admission valve until arrested, when it closes the ports or openings in the admission valve, thereby cutting off the steam before the termination of the stroke without the aid of intervention of the ordinary equilibrium throttle valve. With this method it is necessary to have two induction and two eduction valves, all four receiving a reciprocating motion from a disc or cross lever connected to an eccentric or its equivalent. The cut-off apparatus consists of a cylindrical box through which, and in the direction of its diameter, protrude two bushes, one on each side, capable of sliding therein. Motion is imparted to these bushes in the direction of their length by two plates having angular guides formed on them, and which are connected to the governor in such manner that any variation in speed of the engine will move the plates at right angles to the length of, and will thereby give motion to, the said bushes. Through these bushes is a sliding rod, having adjustable stops or nuts thereon, which sliding rod being connected to a lever on the spindle of the inside valve will drive motion from the said valve through the bushes until arrested by the adjustable stops or nuts, while the outer valve continues its motion, and the ports or openings in it will be closed by the arresting of the inside spindle.—Patent abandoned.

2714 A. MORRALL. *Certain improvements in the manufacture of fish hooks.* Dated September 26, 1867.

This invention consists of a piece of wire bent into, or otherwise caused to assume, such a shape that, when in a normal condition, it nearly represents the letter V, it being understood that at the upper ends of the wire are the barbed hooks. When it is desired to bait the hook, the said upper ends are pressed together, and the lower part or shank of the V-shaped wire being flattened is passed through the mouth of the fish, which is to form the bait until it has passed completely through it. In this manner no separate baiting needle is needed.—Patent completed.

2715 J. JAMESON. *Improvements in the preparation of paper which cannot be tampered with for the removal of writing thereon without detection.* Dated September 26, 1867.

This invention consists in the preparation of a paper which will indicate any tampering therewith whatever. The inventor prints a design or designs in different colours, in or on different media, the nature of the colours and the media being such that part of the design will be effaced or injured by the action of heat, part by the action of chemical gases, part by attrition, part by the action of water, alcohol, ether, or other solvents.—Patent completed.

2716 G. WILKINSON. *Improvements in pumps.* Dated September 26, 1867.

Here the patentee arranges the suction pipe of the pump to rise up at the side of the pump cylinder in a chamber provided for it. The cylinder communicates at its lower end with this chamber, and the cylinder contains a valved piston or bucket having a short and rapid stroke given to it usually by a crank and multiplying gear. The suction valve is mounted on the top of the suction pipe at a level above the piston or bucket, so that this is necessarily at all times immersed in the water. The water is delivered through the piston or bucket passing the clack or valve therein, and it escapes by a spout or delivery pipe at the upper end of the cylinder above the piston or bucket.—Patent completed.

2717 E. T. and C. HORSLEY. *Improvements in the production of a glazed or vitrified surface on cast iron or other cast metal.* Dated September 26, 1867.

In producing castings of iron or other metal, the patentees coat the mould, and any core which may be employed, or either or part thereof, with powdered glass, or it may be furnace cinder or enamel, or other material capable of being vitrified by the heat of the melted metal when it is poured into the moulds, so as to form a glaze or enamel on the surface of the casting.—Patent completed.

2718 J. BRUNTON. *Improvements in machinery for raising water.* (A communication.) Dated September 26, 1867.

Here, on an axis mounted horizontally in suitable bearings, and driven by a bullock mill, or in other convenient manner, are two discs, at a distance apart, and connected the one with the other by bars parallel to the axis, and equidistant from it, and from each other. It is preferred to employ eight such bars, which, with the discs, form a skeleton drum of an octagon form. Over this drum two endless chains pass; they are made with links of iron plate corresponding in length to the sides of the octagon drum, and jointed the one to the other. The chains carry between them buckets which are riveted to them, every alternate link of each chain being riveted to the end of a bucket. The buckets are rectangular, of a depth of about equal to the length of the links from centre to centre, and somewhat less in width; they are riveted to the chains in an inclined position, so that, as each bucket ascends with the water which it has taken from the source, its inner side is higher than the outer. A trough is placed beneath the drum outside the chains on their descending side, and the buckets as they come round discharge the water into it. The apparatus should be driven at a speed which is just sufficient to cause each bucket as it comes round to discharge its water into the trough, throwing it outwards clear of the bucket beneath.—Patent abandoned.

2719 J. JAMESON. *Improvements in the indication of value on cheques, bills of exchange, and other documents.* Dated September 26, 1867.

Here the patentee perforates the cheque, bill, or other document in such a way, or in some conventionally fixed manner, to indicate the amount written on it, and so arranges the perforations that any additional perforation will indicate a reduced value; or, he prints, water marks, or otherwise indicates on the cheque, bill, or other document a scale or scales of amount, cutting through, tearing or perforating which at a certain place or places will indicate the amount, or an approximation to the amount, stated in writing; or, he cuts off certain parts, or cuts, perforates, or tears the bill, cheque, or other document in any convenient conventionally understood manner, so that any further cutting, perforation, or tearing would indicate a reduced value. Silk threads may also be run through the paper, so as to be involved in the perforation if desired. This mode of indication of value could also be applied to affixed stamps, the cutting, perforation, or tearing of which might be made a legal obliteration.—Patent completed.

2720 A. V. NEWTON. *Improved apparatus applicable to*

Digitized by Google

turning and screw cutting. (A communication.) Dated September 26, 1867.

This invention relates to cutting screw threads on pipes, bolts, and rods, whereby the work may be done with far greater rapidity than hitherto, and consists, first, in an improved clamp for clutching the pipe or rod to be acted upon, and causing it to turn with the mandril whenever the latter is turned, the pipe or rod being released when the rotation of the mandril ceases, the clamp being consequently self-acting, and admitting of the pipes or rods being inserted in and withdrawn from it without any appreciable loss of time. The invention consists, second, in a die for cutting the screws on the pipes or rods, whereby the die may be made at the will of the operator or attendant, to grasp the pipe or rod, or be released therefrom.—Patent abandoned.

2721 J. FORDRED. *Improvements in bleaching and purifying paraffin.* Dated September 26, 1867.

This invention is performed in the following manner:—Having melted the crude paraffin and allowed the impurities to subside in the usual way, the inventor runs the liquid paraffin into a vessel, and having raised the temperature to 260deg. Fah., or thereabouts, he adds thereto sulphuric acid, and agitates the mixture well (preferring hot air for that purpose). He then keeps it warm to allow the tar and colouring matters to deposit. After it has become clear, he draws it off from the sediment, and boils it in contact with a weak solution of glue, by the aid of free steam, until the glue has taken up and combined with any free sulphuric or sulphurous acid the liquid paraffin may contain; or it may be washed with the solution of glue by mechanical means; on allowing the whole to repose, the liquid paraffin will become transparent and bright. Or in lieu of this glue treatment he draws off the clear liquid paraffin and mixes it with ground Fuller's earth, agitates it, and allows it to settle. It is then drawn off and mixed with about 15 per cent. of spirit (more or less), and run into tins and allowed to cool. When thoroughly set, the cakes are submitted to hydraulic pressure in the usual way, and, finally, filtered through animal charcoal, as is well understood.—Patent abandoned.

2722 J. H. JOHNSON. *Improvements in apparatus for supplying steam boilers with water.* (A communication.) Dated September 26, 1867.

This invention relates to a peculiar construction and arrangement of self-acting feed apparatus for supplying water to steam generators, and consists in the use of a vibrating or oscillating horizontal hollow lever or beam, working on a centre in three brackets or supports attached to a bed plate, which bed plate is secured to the top of the boiler. On each end of this lever or hollow beam there is formed a closed chamber in free communication with the interior of the beam. A central partition formed transversely across the middle of the hollow beam prevents any communication between the two opposite ends of the beam, and between the two chambers carried thereby. To one of the supporting heads or brackets there are fitted a steam and a water supply pipe. The steam pipe descends inside the boiler to a little below the proper water level. The water supply pipe may consist of an injector, or it may receive its supply from a head of water, or otherwise, a cock being provided for shutting off the water when required. In the faces of the two buckets or heads immediately adjoining and in contact with the sides of the beam there are formed ports or passages which communicate with the interior of the generator, and with other ports or passages made in both sides of the beam, and situate on opposite sides of the internal partition. When the beam is caused to vibrate on its centre,—that is to say, when one end or the other is depressed, a communication is established by the ports and passages hereinbefore referred to between the interior of the boiler and one or other, as the case may be, of the closed chambers carried by the beam, and also with the water supply pipe.—Patent abandoned.

2723 T. and O. VAUGHTON. *An improved necktie ribbon or other connector for ladies' or gentlemen's use.* Dated September 26, 1867.

This fastener is adapted for holding and attaching the bow ends or parts of a neck-tie, ribbon, or kerchief, and is composed of a front part (which may be ornamented to any extent by being chased, engraved, jewelled, enamelled, or otherwise), and to this part a back is attached by a convenient joint, to which part, by preference, a stud or other convenient elastic or non-elastic projection is applied, for the better holding (from lateral action) the tie or ribbon on its inside; an additional stud may be used for attachment with the collar or neck-band of the shirt, or other part of dress. The back and front parts are united by a spring snap or other joint.—Patent abandoned.

2724 J. E. H. ANDREW. *Certain improvements in looms for weaving.* Dated September 27, 1867.

This invention is not described apart from the drawings.—Patent completed.

2725 R. ADAMS. *Improvements in apparatus for extracting cartridge cases from breech-loading firearms.* Dated September 27, 1867.

This invention relates to improved arrangements of mechanism for extracting or withdrawing exploded cartridge cases from breech-loading firearms having hinged breech-blocks for closing the breech end of the barrel, the act of opening the breech being the means by which the extractor is actuated to withdraw the cartridge case out of the breech end of the barrel. For this purpose, the inventor mounts the finger of the extractor (which acts upon the rim of the cartridge case to withdraw it from the barrel) upon a slide, mounted so as to move to and fro in a groove formed in the breech-piece, in a parallel line, or nearly so, with the barrel. Upon the upper surface of the slide which carries the extractor an incline is formed, which is acted upon by another incline formed on the breech-block, so as to move the slide and extractor outwards from the breech end of the barrel when it is opened. When the breech-block is closed, the slide carrying the extractor is moved back to its former position by a lever arm actuated by a spring mounted upon the breech-piece.—Patent abandoned.

2726 M. SAMUELSON. *Improvements in sewing machines.* Dated September 27, 1867.

Provisional protection has not been granted for this invention.

2727 F. FREW and J. SPEIRS. *Improvements in looms for weaving ornamental fabrics such as leno and muslin curtains.* Dated September 27, 1867.

In carrying out these improvements a plain heddle leaf is arranged to act on one half of the warps, and is placed behind the harness. The other half of the warps, and of course alternating with those acted on by the back heddle leaf, are acted on by the harness to produce the pattern in the ordinary way, and may be termed the harness warps. In front of the harness there is placed a gauze or "doup" heddle leaf arranged for producing a full gauze weaving action. The warps acted on by the back heddles are passed through the "doup" loops or heddles, whilst the harness warps are passed through the spaces between the front heddle loops. There are four sheds in the cycle of movements, and separate single weft shots are passed through each shed. The jacquard apparatus is actuated by a cam movement so as to operate at every alternate shot only. After one harness shed the back heddles are raised for the second shed, and with them the bar to which the "doup" loops of the front heddles are attached, which action raises the heddle warp threads on, say, the left hand sides of the respective adjacent harness warp threads. After the third shed, which is a harness shed, the front heddles are raised for the fourth shed, and have the effect of raising the heddle warp threads on the other or right hand sides of the harness threads. The heddle warp threads are passed over a separate bearer at the back of the loom, and by a periodical cam movement this bearer is moved forward so as to slacken that portion of the warps sufficiently for the gauze action at the same time that the "doup" loops are made free to be drawn up by the raising of their bar, and unequal strain on the warps is thereby prevented.—Patent abandoned.

2728 A. M. CLARK. *An improved hat-blocking machine.* (A communication.) Dated September 27, 1867.

This improved machine consists of three different elements combined in one machine. The first element is a mechanism for blocking the crown of the hat, consisting of a number of expansible bars, any suitable mechanism being employed, and the patentee does not claim any improvement thereon. The second element consists in a ring for breaking the band of the hat, which is constructed so as to be capable of a downward motion, which motion is to be given to the ring after the blocking of the crown and the stretching out of the brim has been completed. The third element consists in a series of clamps placed in a circle to seize the brim, which clamps are in an inclined position nearly fitting the conical shape of the hat body when the hat body is to be placed on the machine. These clamps, when the stretching of the brim is to take place, receive a double motion, they being brought up to a horizontal position and then expanded.—Patent completed.

2729 S. PARR and A. STRONG. *Improvements in the construction of buildings, arches, bridges, and such like structures, and in the floors of buildings and in other situations.* Dated September 27, 1867.

This invention comprises various features, among which are the following:—As regards the roofs of buildings, the inventors propose to construct them as follows:—The framework of the roof being principally of metal, they cover the same by fixing a wood centre to the framework by any convenient means, the said centre being made the desired shape and covered with sheet metal, if necessary. Upon these centres they arrange metallic or earthenware tubes or half tubes, in combination with concrete, or they form a coating of concrete only, in which case they mix together ballast, broken brick, or pottery, and Portland cement in varying proportions, according to the strength required, and this concrete they lay or spread on the wood centre, or not, as required, to the desired thickness, the outer surface being worked into shape, as in plastering. Where half round tiles or half tubes are used, they might simply be laid on the wood centre, and their outer surfaces be covered with liquid or semi-fluid cement, or flue concrete; they then apply a coating or covering of ordinary concrete to make up the required thickness. Cylinders or tubes may be laid in the above manner, and be similarly covered. They propose to so fix and dispose some of the tubes of the roof or covering as that they may be used as ducts for the passage of air, water, gas, or smoke when required. They also propose to fix the chimney pots on the roof, and thus dispense with chimney shafts. They propose to form openings for windows by employing burbs of wood, iron, or terra-cotta to receive the sash frames or skylights, and they further propose to bed iron fastenings in the concrete for attaching internal or external framings.—Patent abandoned.

2730 P. and F. S. COCKER. *Improved apparatus for transmitting signals in railway trains.* Dated September 27, 1867.

The object here is to enable signals to be communicated to the guard or to the engine driver, or simultaneously to both guard and engine driver, of a train in motion from a passenger in any compartment of the train, and also from the guard to the engine driver, and vice versa. This the inventors effect by fitting to the roof of each carriage an apparatus which will transmit an endway motion imparted thereto by the pulling of a pendant cord, throughout the length of the train, which motion may be made to sound an alarum, throw up a visible signal, or set the whistle of the engine in action.—Patent abandoned.

2731 L. DE LA PEYROUSE. *Improvements in the treatment of paraffin, fatty, and resinous matters.* (A communication.) Dated September 27, 1867.

Raw or crude paraffin of commerce is a mixture of paraffin, tar, carbonaceous matters, heavy mineral oils, and colouring matters, and the purification or refining of such paraffin, as well as its decoloration, consists in the separation of the before-mentioned substances. In order to effect the separation of the tarry and carbonaceous matters the patentee employs certain chemical agents which possess the property of removing the before-mentioned impurities, and of concreting a portion of the heavy oils contained in the paraffin. He also employs such chemical agents as will effect the precipitations of the tarry matters contained in the crude paraffin, as well as the precipitation of the colouring matters, so as to yield paraffin entirely free from tarry matters, and both limpid and transparent, and of a white or grey or pale yellow colour. He also adopts as a method of separating the tarry matters from the crude paraffin, maintaining the same in a state of fusion for a given time at a temperature of about 60deg. Centigrade. The tarry matters and other impurities, being denser than the paraffin, sink, and the paraffin is withdrawn in a purified condition.—Patent completed.

2732 F. BRANSCOMBE. *Improvements in means or apparatus employed in drilling, cutting, and ornamenting metal, wood, and other substances.* Dated September 27, 1867.

Here the inventor employs revolving cutters of forms suitable to the work to be produced, such cutters being mounted upon an axis to which rotary motion is given in any suitable manner, as is well understood. The material to be operated upon is fixed in any suitable manner to a table or holder, which is mounted upon a pin carried by a slide, which is capable of being worked to and fro upon suitable guides by a screw, in a similar manner to the slide rest of a lathe, such guides being carried by a circular plate, on the periphery of which are formed teeth into which a suitable screw takes, and by which rotary motion may be communicated to such circular plate. The screw above mentioned is also carried by a slide working upon suitable guides, as before described with reference to the first-mentioned slide. To the last-mentioned slide is fixed a bar or rod provided with a suitable groove, in which moves a stud or projection from a suitable rod or bar, carried by the table or holder to which the material to be operated upon is fixed. The last-mentioned guides are fixed to a plate which is capable of being turned into any desired position, and the edge or surface of which is provided with suitable marks or divisions to enable it to be turned to any desired angle.—Patent abandoned.

2733 J. and J. A. HUGGETT. *Improvements in the manufacture of horse nails and other nails, and in machinery used therein.* Dated September 27, 1867.

Here the patentees employ a hammer worked by power, by which a regular reciprocating motion is given to it. On the face of the hammer are two dies, one corresponding in form to the side of the nail, and the other to its edge. This hammer works upon an anvil, also having the incline or bevel of the nail formed upon it. The bar of iron which is to be drawn down to form a nail is received in a holder which turns it one quarter round, and shifts it sideways from one die of the hammer to the other after each blow, so that the bar may be alternately struck on the side and edge, and alternately by one and the other of the dies which the hammer carries. The holder for the bar to be drawn down may conveniently be an axis carried by a slide; the axis is connected with the hammer so that it turns one quarter round between each stroke, first one way, then the other.—Patent completed.

2734 F. MEYER and W. WAINWRIGHT. *Improvements in the manufacture of candles, and in moulds for the same.* Dated September 27, 1867.

Here the end of the candle which fits into the socket is made with grooves or recesses in it which penetrate towards the centre of the candle below the surface of the shaft, so that, by rubbing away from the end of the candle the ridges or projections which separate such grooves or recesses, the candle may be made readily to adapt itself to a socket of smaller diameter than its shaft.—Patent completed.

2735 C. MOLE. *Improvements in the preparation of soles and heels for boots and shoes.* Dated September 28, 1867.

Here the inventor proposes to render soles of boots and shoes, made of leather, gutta-percha, india-rubber, or analogous material, stronger and more durable in wear without destroying the elasticity of the material. He proposes to use bolts or pins of solid metal or composite metal, and to insert them (through holes prepared in the leather or other material) into the sole before the boot or shoe is made, in order that boot or shoe soles thus prepared may be supplied to the bootmaker perfect, and ready for use.—Patent abandoned.

2736 H. A. BONNEVILLE. *A new and improved process of treating skins in order to separate therefrom the hair and wool, and in the preparation of the hair for the manufacture of hats.* (A communication.) Dated September 28, 1867.

The patentee claims, first, the use of the sulphuretted sulphydrate of calcium engendered in the very tissue of the skin for depilating. Second, the leather obtained by means of this process with the skins of rabbits, hares, rats, and beavers. Third, the preparation of the hair to be used in the manufacture of hats with a solution of sulphur.—Patent completed.

2737 L. LAINE. *An improved fan.* Dated September 28, 1867.

The object here is to combine with or affix to fans, whatever form they may assume, or whatever material they may be made of, either a hand glass, binocle, or spy glass, or any other such-like or analogous optical instrument, and the invention consists in lodging these objects in a cavity provided in one or both of the fan sticks, as may be required. The hand glass, binocle, or spy glass, furnished with its mounting, is retained in the cavity by a spring actuated by a thumb-piece projecting on the side of the fan stick, which has only to be pressed to open it by the barrel spring actually in use.—Patent abandoned.

2738 A. WARD and C. G. VIRGO. *The adaptation of materials specially prepared for the manufacture of certain articles of wearing apparel.* Dated September 28, 1867.

Here the inventors impart to such linen or cotton, or linen and cotton fabrics, a glossy surface by means of heat and pressure, jointly applied in what is known as a hot press of ordinary construction, care being taken that each side of the fabric is glazed equally. The materials thus prepared (which may, if desired, be embossed, figured, or illuminated by well known means) will have the appearance of silk or satin fabrics.—Patent abandoned.

2739 J. H. JOHNSON. *Improvements in the manufacture of railway wheels.* (A communication.) Dated September 28, 1867.

This invention relates to the manufacture of "chilled" railway wheels, and has for its object the avoiding the danger of fracture arising from the great strain or tension in the metal produced by the cooling of the periphery of the wheel after casting. According to this invention it is proposed to cut away or remove a portion of the "chill" under the flange of the wheel, so that, in moulding and casting, the outer part of the flange will rest on sand, and thereby cause the flange of the wheel in casting to have a full and perfect edge. The "chill" is provided with a number of internal recesses, in which are placed cores which form recesses in the rim of the wheel. These recesses in the wheel are filled up by driving roughened or file-cut pieces of steel therein, or by melting and pouring therein hard metal, or they may be otherwise filled up.—Patent completed.

2740 G. R. SOLOMON. *Improvements in apparatus for registering passengers travelling in public vehicles.* Dated September 28, 1867.

The patentee claims, first, the novel employment and use of lengths or ribbons of tickets rolled around a shaft, and caused to issue or unroll as required, by means of elastic surfaced delivery rollers, actuated by a handle outside the case containing the tickets and delivery rollers. Second, preventing the rollers turning in a reverse direc-

Digitized by Google

tion, whereby such tickets might be returned to the box. Lastly, the general arrangement, combination, and construction of the apparatus as described, set forth, and illustrated in the drawings.—Patent completed.

2741 E. LEVER. *Improvements in lamps.* Dated September 28, 1867.

The object here is to enable more air to pass into the vessels containing oils, hydrocarbons, or gases to be consumed for the production of light than can be obtained from the ordinary single air holes with which lamps have hitherto been provided, the increased supply of air causing a greater intensity of light, and the prevention of noxious fumes. To the upper part of each vessel the inventor fixes two or more tubes open to the atmosphere, for causing one or more currents of air to circulate through the vessel, and thus enable more oxygen to be supplied.—Patent abandoned.

2742 H. KELLOGG. *Improvements in the manufacture of hats, and machines for producing the same.* Dated September 28, 1867.

This invention relates to a peculiar formation of or coating for hat bodies, and machinery for performing the same, and consists in taking vegetable pulp, whether perfectly dry, or in the partially fluid condition in which it is usually employed for commencing to form it into sheets of paper in paper making machinery, and then mixing the same with a sufficient quantity of water (say in the proportion of fifty to eighty parts or thereabouts of water to one of pulp), in order to entirely separate the fibre from each other, that they may all be diffused through the water, similarly to the manner in which particles or motes float in the air, then introducing in to the same animal fibre, such as wool, and from this mixture forming a hat body by placing the mixture into a vessel above a former constructed from perforated metal, or other suitable permeable material, constantly agitating the mixture to preserve the above-stated condition, then, by suction from below, or pressure above, forcing the water through the former, leaving the fibrous mixture thoroughly mingled, and packed in sufficient quantity to form the body. Reference to the drawings is essential to a full description of the invention.—Patent abandoned.

2743 J. ELDER. *Improvements in the construction and mode of propelling and manœuvring floating batteries and other vessels intended for the purposes of naval defence and attack.* Dated September 28, 1867.

The specification of this invention is too elaborate to be quoted here at sufficient length for an intelligible abstract. We may, possibly, describe and illustrate the invention in a future number.

2744 M. HAMER. *Improvements in machinery or apparatus for manufacturing india-rubber tubing.* Dated September 28, 1867.

This invention consists in manufacturing india-rubber tubing by drawing strips of the material through a trumpet-formed orifice, whereby the edges of the said strips are brought together.—Patent completed.

2745 T. PRIDEAUX. *Improvements in blast furnaces or cupolas.* Dated September 28, 1867.

This invention relates to smelting iron from the ironstone, and entirely dispenses with the water tuyeres as at present in use. The patentee constructs a passage or pipe round the furnace between the inner and outer brickwork under the boshing, and above the level of the dam; from this passage a number of perforations lead into the interior of the furnace, the blast being let into this passage and through the perforations, and thereby spreading over the whole surface of the furnace. By these means great advantage is derived, as the passage around the furnace acts as a heating stove, and thereby a great degree of heat is attained before the air or bloss passes through the perforations into the interior of the furnace. The invention also consists in a method for drying or calcining the ironstone before entering the furnace. The patentee constructs at the top of the furnace vertical gratings with valves at the dip; the stone is tipped or thrown on the gratings, the gases and heat from the furnace ascend through the gratings, and thereby dry or calcine the stone, as may be found necessary. The valves at the dip of the gratings are constructed for discharging the stone from the grating into the interior of the furnace.—Patent completed.

2746 T. SILVER. *An improved lubricating packing.* Dated September 28, 1867.

This invention consists in the employment of dry powdered substances, such as steotite, or any lubricating species of talc, brimstone, and stearine, separately or in combination, in connection with a tubular rope or gasket constructed of any suitable fibrous material, the powdered substance or filling alone forming the centre or core of the said rope. The powdered substance, during the process of construction, is distributed through the body of the rope or fibrous material, the object of the core being to lessen the cost of production and increase the supply of lubrication.—Patent abandoned.

2747 B. DOBSON and R. HALLIWELL. *Improvements in mules for spinning and doubling.* Dated September 30, 1868.

This invention relates to mules for spinning and doubling cotton, wool, or other fibrous substances (when two speeds are required), and consists in making the horizontal rim pulley shaft in two parts extending nearly the whole length of the headstock. The rim band pulley for the slow speed is on the end of one shaft, and that for the quick speed on the other shaft. The driving pulleys are placed at the junction of the above shafts, one pulley fixed to each shaft, and a loose pulley placed between the above pulleys. An endless band passes from one rim band pulley to the other over suitable guide pulleys to the pulley or pulleys inside of the mule carriage for the purpose of driving the spindles at the speeds required, and the band is tightened by making the guide pulley inside the carriage adjustable, the said guide pulley being supported in a frame actuated by a screw or other equivalent. By the above arrangement the speeds can be easily varied to suit the counts required by changing the ring band pulleys. The other portions of the mule are arranged to suit the above object.—Patent completed.

2748 C. P. JONES. *A new or improved apparatus for removing adhering matters from the bottoms and sides of ships or other navigable vessels whilst at sea.* Dated September 30, 1867.

This invention consists in employing a jointed scraper, rendered buoyant by corks or otherwise, so as to closely surround or encircle the body of the ship, and admit of being heaved or dragged fore and aft whilst afloat by means of guy ropes and lines attached to the apparatus.

The said scraper or apparatus is formed of a series of bars or plates of iron jointed longitudinally together to a keel piece through the medium of transverse rods and rivets, the said corks or otherwise being fixed between or upon the transverse bars and the sides of the said apparatus to give it the requisite buoyancy, and enable the scraper to impinge against the bottom and sides of the vessel whilst being worked from stem to stern, or in the opposite direction.—Patent completed.

2749 T. WESTON. *An improvement or improvements in the manufacture of ornamental metallic tubes.* Dated September 30, 1867.

The patentee claims making ornamental tubes by coating or covering a tube or foundation of iron, or a tubular or solid core or foundation of steel, by a drawing process with a thin metallic tube, and passing the compound tube or tube and solid steel core or foundation through ornamental rolls, whereby the outer thin tube is ornamented or impressed with the pattern or ornament upon the said rolls, substantially as described.—Patent completed.

2750 I. DIMOCK. *Improvements in apparatus to be used for boiling eggs and for like purposes.* Dated September 30, 1867.

The patentee claims, first, the use of a fluid in a vessel surrounded by a slow heat-conducting material, or an air cavity, as described. Second, the use of a fluid in a case arranged to act upon a piston or diaphragm which will transmit movement so as to release a catch and ring a bell, release a catch and allow a spring or weight to lift the eggs out of the boiling fluid, and ring a bell if required, as described. Third, the combination and arrangement of the mechanism or apparatus forming the instruments described.—Patent completed.

2751 W. JAMES and W. HILL. *An improved method of, and apparatus for, attaching and securing watch chains and similar articles to vests and other garments.* Dated September 30, 1867.

This apparatus consists of a plate formed of metal or other material possessing sufficient hardness and rigidity for the purpose to which it is to be applied, and on one side of which is placed a hook-like shank. To the other or front side of the plate is attached a ring, either split or otherwise, to which the chain is appended by means of another ring, or through which the bar ordinarily attached to chains commonly known as "Albert" chains may be passed. In order to fix this contrivance to the garment, a perforation or eyelet hole is made or formed in the latter, through which the hook-like shank of the beforementioned plate is passed. A plate of metal, or other suitable material, is then placed on the other side of the garment, the hook-like shank being passed through a hole or slot formed in the said last-mentioned plate, and to which is attached a small bent spring, which, working on a hook-like shank, securely holds the front plate in the desired position.—Patent completed.

2752 J. DONALD. *Improved arrangements for burning oil in furnaces.* Dated September 30, 1867.

These improved arrangements comprise the making of a furnace space or combustion chamber which has its bottom and sides lined with firebrick, and which is also arched or roofed over with firebrick. In the midst of this combustion chamber there is constructed, also of firebrick, what may be termed an ignition block or pier. The oil to be burned is admitted by a pipe nozzle placed so as to direct a jet of the oil towards or against the ignition block, and apertures are provided for the admission of air, by preference on the same side, so that the air will flow inwards in the same direction. In one modification no force but that due to a very small head is used for projecting the oil into the combustion chamber; but in another modification (and which the patentee prefers, as it is applicable where a more intense heat is required) a jet of steam (which he prefers to have superheated, although common steam will answer quite well) is made to project the oil in with considerable force.—Patent completed.

2753 J. DEWAR. *Improvements in preserving potatoes.* Dated September 30, 1867.

This invention consists in subjecting potatoes to the action of sulphurous acid for the purpose of preserving them in a condition suitable for food. The patentee does not saturate the substance of the potato throughout with the acid, but merely subjects the surface to the action thereof.—Patent completed.

2754 C. HONEGGER. *An improved loom for weaving figured fabrics.* Dated September 30, 1867.

This invention relates to a novel description of power loom for weaving figured fabrics, and the same consists, first, in an improved arrangement of the vertical wires or hooks of the Jacquard apparatus, and parts connected therewith, so as to allow the said hooks to work the shuttles according as required by the pattern cards. Second, in an arrangement for carrying each of the shuttles, and according as required by the pattern in the position for being acted upon by the picker or shuttle-driver, and for keeping the shuttle boxes in position during each pick. Third, in a peculiar arrangement and combination of parts for causing the main arbor to procure the working of the batten or lathe, the shuttles, the Jacquard apparatus, and other working parts of the loom.—Patent abandoned.

2755 J. CLARK. *Improvements in locomotive engines and their permanent ways.* Dated September 30, 1867.

These improvements have for their object to increase the tractive power of locomotive engines upon steep gradients. The first improvement consists in making the driving wheels with two flanges or tyres, or adding second wheels to ordinary driving axles. The inventor makes the second tyre or additional wheel of less diameter than the first or ordinary tyre and wheel, and lays down a second rail for the lesser wheel to run upon; the said second rail is to be fixed at the side of the ordinary rail when an increase of the tractive power of the engine is required. The difference in the level of the said rails is determined by the difference in the radius of the two driving wheels; the height of the second rails in all cases is to be such that, when the engine is running thereon, and bearing upon the second tyre or lesser wheels, the first tyre or ordinary wheels may run clear of the ordinary rails of the permanent way. The lesser diameter of the second tyre or wheel, and the raised rail, increase the tractive power of the engine.—Patent abandoned.

2757 T. BIRD. *Improvements in furnaces, fireplaces, and firebars for the consumption of smoke and gases arising from products and the non-consumption of firebars.* Dated October 1, 1867.

This invention has reference to a patent granted to J. Robertson, dated October 8, 1866 (No. 2586). The principal part of J. Robertson's invention consisted in having at the back of the furnace a hollow box bridge, with perforations at the top, and also placing near the front of the bridge a number of perforated tubes, the holes in the bridge and perforations in the tubes being for the supply of air from the ashpit, assisting the combustion of the smoke and gases. The present inventor employs the hollow box bridge with perforations at the top, and also the perforated tubes, but in connection with them he uses hollow firebars having apertures near their front ends, and opening at the back into the perforated tubes or perforated box bridge, for enabling the air to be heated by the fire in the furnace before it arrives at the said tubes and box bridge, and also to prevent the bars from burning and wasting so much as in ordinary practice. And where two bars are required he makes them with male and female joints to prevent the ashes from getting in, as also to insure the air passing more directly through them.—Patent abandoned.

PROVISIONAL PROTECTIONS.

Dated December 21, 1867.

3625 B. Engel, Lawrence-lane, Cheapside, merchant. A new and improved composition for extracting ink and iron mould from linen and woollen fabrics. (A communication.)

Dated January 13, 1868.

118 W. Firth, Rose Villa, Viewforth, Edinburgh. Improvements in valves made from india-rubber or other similar elastic material, the said valves being applicable in the construction of fluid or gaseous pumps, enemas, syringes, spray producers, and other instruments where valves are in use.

Dated March 2, 1867.

705 L. Roman, Paris. Improvements in apparatus for obtaining motive power from rivers or streams of water, and for facilitating boats ascending and descending rivers or streams.

Dated March 4, 1868.

753 C. Schinz, Faubourg de Saverne, Strasbourg, France, engineer. A process for the partial elimination of the nitrogen from the products of combustion and furnaces and apparatus connected therewith.

Dated March 12, 1868.

849 W. E. and F. A. Bush, Commercial-road, East. A new or improved trap for catching mice, rats, animals game, or vermin.

Dated March 13, 1868.

856 E. K. Dutton, engineer, and J. and H. Holme, merchants, Manchester. Improvements in sewing machines.

Dated March 18, 1868.

927 S. Wenkheim, Regent-street, hosier. A mode or method of combining a shirt and waistcoat, or portions thereof, so as to be worn either as a waistcoat and shirt, or as a shirt only.

Dated March 19, 1868.

941 R. W. J. Trueman, Queen-street, Belfast. Improvements in machinery or apparatus for collecting and removing mud from the surface of roads and streets.

Dated March 20, 1868.

951 W. Taylor, Driffield, Yorkshire, and C. E. Taylor, Bradford, Yorkshire. Improvements in stands or tables for sewing machines and other purposes.

Dated March 21, 1868.

961 G. Macdons, Downshire Hill, Hampstead, merchant, and O. Hilliard, Pembroke-road, Dublin. Improvements in means and appliances for conveyance, transport, and locomotion. (A communication.)

963 J. O. Spong and J. F. Haddaway, Fulham-road, Middlesex. Improvements in blow pipes.

965 H. Bessemer, Queen-street-place, Cannon-street, City. Improvements in the manufacture of refined iron and of malleable iron and steel

967 H. Bessemer, Queen-street-place, Cannon-street, City. Improvements in the manufacture of malleable iron and steel, and in apparatus used in such manufacture.

Dated March 23, 1868.

969 E. K. Dutton, Smithy-door, Manchester. Improvements in valves employed to regulate the flow of water.

971 T. Pope, Twickenham, Middlesex. Improvements in braces or suspenders. (A communication.)

973 S. Holmes, High Holborn. Improvements in lamps for burning oils and spirits.

977 C. M'Dermott, Devereux-court, London. An improved indelible pencil for marking linen and other fabrics.

979 C. N. Leroy, Rue Eugenie Levallois-Perret, near Paris. Improvements in grease cups or apparatus for lubricating machinery.

981 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in metal ties or bands for securing bales of cotton or other substance. (A communication.)

983 E. Vignier, Fowkes-buildings, City, merchant. Improvements in distilling and rectifying spirits, and in apparatus employed therein.

985 A. V. Newton, Chancery-lane. Improvements in thrashing machines. (A communication.)

Dated March 24, 1868.

987 J. S. Farmer, Canterbury-road, Kilburn, railway signal engineer. Improvements in the apparatus for, and in the means of, communicating or transmitting signals between the parts of a railway train, and for signalling on railways in connection with train working.

989 H. Burgess, Battle, Sussex, draper. Improvements in the construction of rails for railways and tramways.

990 W. E. Gedge, Wellington-street, Strand. An improved smoke-consuming fireplace or furnace. (A communication.)

991 W. R. Boothby, Adelaide, South Australia. An improved combination of mechanism to produce rotatory motion in engines.

992 T. W. Fuller, Leamington, Warwickshire, coach builder. Improvements in carriages.

993 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in watches, chronometers, and clocks. (A communication.)

994 E. Gray, Sheffield, edge tool manufacturer. Improvements in the manufacture of metal bars intended to be made into horse-shoes and other articles.

997 J. A. Farrar, master mariner, and B. R. Huntley, ship chandler, Hartlepool, Durham. Improvements in ships' hatches, and in ventilating the holds and cabins of ships.

999 D. Lewis, Ranelagh-street, Liverpool. Improvements in portable tables.

1001 C. Harris, Manchester. Certain improvements in machinery or apparatus to be employed in the manufacture of paper bags.

1002 J. Antill, Wandsworth, Surrey, plasterer. Improvements in stench traps.

1003 A. V. Newton, Chancery-lane. Improvements in the construction of pocket knives. (A communication.)

Dated March 25, 1868.

1006 R. Little, Greenock, Renfrewshire, merchant. Improvements in reducing the temperature of air, in producing ice, in preserving animal and vegetable substances, and in apparatus therefor. (A communication.)

1007 A. Elliott, Failsworth, near Manchester, practical mechanic, and J. Barker, engineer, Oldham, Lancashire. Improvements in apparatus for lubricating axles and bearings and other frictional surfaces.

1009 A. M'Glashan, Coal-yard, Drury-lane, engineer, and J. Hendry, Arlington-street, New North-road, back and vat maker. Improved machinery or apparatus for mashing substances employed in the making of fermented liquors.

1011 J. Warburton, jun., Sandal, Yorkshire. Improvements in steam engines.

1012 G. Hayhurst, Bury, Lancashire, tin plate worker. Improvements in drying cylinders employed in sizing and other machines.

1013 W. Buck, Upper Tooting, Surrey, engineer. Improvements in machinery or apparatus for working and locking or controlling railway points and signals.

1014 T. Lane, Birmingham. Improvements in looms for weaving.

1015 C. E. Brooman, Fleet-street, City, patent agent Improvements in machinery for the manufacture of paper tubes specially intended for use in spinning machinery. (A communication.)

1016 S. Fisher, Strand, church decorator. Improvements in the ornamentation of tiles to be used for the purposes of mural and other decoration.

1017 J. Plant, Sheffield, dram flask maker. Improvements in dram flasks.

1018 A. V. Newton, Chancery-lane. Improvements in spinning machinery. (A communication.)

1019 W. Richardson, Oldham, Lancashire. Improvements in machines for burring or cleaning wool.

1020 T. Whitehouse, Wednesbury, Staffordshire, engineer. Improvements in blast furnaces.

1021 T. Sagar, machine maker, T. Richmond, cotton manufacturer, and C. Catlow, overlooker, Burnley, Lancashire. Improvements in looms for weaving.

1022 J. Anderson, Ramsbottom, Lancashire, manager. Improvements in machinery employed for carding wool, cotton, and other fibres.

1023 J. Jameson, Catherine-terrace, Gateshead, Durham, engineer. Improvements in the preparation of safety paper.

1024 H. G. P. Meade, Lieut. in the Royal Navy, Belgrave-square, Middlesex. Improvements in firearms, and in cartridges, projectiles, and torpedoes.

1026 W. P. Piggott, Argyll-street, Middlesex, electrician. Improvements in transmitting electric telegraph messages, and in apparatus employed therein.

Dated March 26, 1868.

1027 E. J. J. Dixon, Bangor, North Wales, engineer. Improvements in machinery for reducing, smoothing, facing, or otherwise working and manufacturing slate, and other stone and materials.

1028 J. T. King, Liverpool. Improvements in apparatus for dressing millstones.

1029 W. Oram, Salford, Lancashire. Certain improvements in hydraulic presses, and in the apparatus connected therewith.

1030 M. B. Orr, Glasgow, merchant. Improvements in arrangements for drying and preserving animal and vegetable substances. (A communication.)

1031 W. H. S. Aubin, Wolverhampton, machinist. Improvements in, and additions to, cocks and taps for drawing off liquids and gases from pipes, casks, or other vessels.

1032 T. Bettney, Manchester, commercial traveller. An improvement in paper cutting machines, envelope and label punching machines, and to other similar machines for punching shapes.

1033 H. Davey, Victoria Chambers, Westminster, engineer. Improvements in steam engines, part of which is applicable to steam pumps.

1034 W. Clark, jun., Dunfermline, Fifeshire, and J. Clark, Paddington, Middlesex, engineers. Improvements in locomotive engines, in part applicable to steam engines generally, and to railway and other carriages.

1035 M. Havenhand and J. Allen, Dronfield, Derbyshire. Improvements in pistons.

1036 J. Cocks, Regent-street, Middlesex, tailor. Improvements in the making of trousers, and in the manufacture of materials for the same.

1037 W. Manwaring, Banbury, engineer. Improvements in the construction of reaping and mowing machines.

1038 W. D. Cliff, Wortley, Yorkshire, brick and tube manufacturer. Improvements in furnaces or kilns for the burning of bricks, pottery, iron ore, and other similar substances.

1039 W. S. Page and R. East, Nine Elms Wharf, Nine Elms, Surrey. Improved mechanical arrangements applicable to steam boilers and the cylinders of steam and other motive power engines for preventing the priming thereof, and for lubricating the pistons and cylinders of engines.

1040 B. Browne, King William-street, City. Improved machinery for the manufacture of collars, cuffs, and other articles of dress made of paper or paper and cloth combined. (A communication.)

1041 S. Perry, Red Lion-square, Middlesex, and F. Brampton, Birmingham. Improvements in letter clips, bill files, and other similar clips or suspenders.

1042 J. Lyall, New York, U.S. Improvements in looms for weaving.

1043 J. H. Johnson, Lincoln's Inn-fields. Improvements in lamps for burning liquid hydrocarbons. (A communication.)

1044 T. Routledge, Ford Works, near Sunderland, and W. H. Richardson, Springwell Paper Works, Jarrow-on-Tyne. Improvements in bleaching esparto and other fibrous substances used in paper making.

Dated March 27, 1868.

1045 A. Warner, Laurence Pountney-lane, City. Improvements in the manufacture of cement.

1047 I. Bates, manager, and J. Taylor, engineer, Dukinfield, Chester. An apparatus for cleaning the flues of boilers and boiler seatings.

1049 J. Maurice, Langham-place, Middlesex, dentist. Improvements in the means or method of producing optical illusions.

1050 F. Bauman, Wellington-street, Strand. The preparation of a certain combination of chemical substances, and its novel application to the treatment of wood or other fibrous material in the preparation of paper pulp.

1051 G. Hodgkinson, Manchester. Improvements in the method of producing designs upon woven fabrics.

1052 G. Davies, Serle-street, Lincoln's Inn. Improvements in the construction, arrangement, and application of steam engines. (A communication.)

1053 P. Adie, Pall Mall, mathematical instrument maker. Improvements in means and apparatus for shearing sheep and clipping horses and other animals.

1054 C. E. Brooman, Fleet-street, City, patent agent. Improvements in breech-loading firearms. (A communication.)

1055 C. B. James, Redditch, Worcestershire, needle manufacturer. Improvements in securing and wrapping up needles.

1056 W. E. Newton, Chancery-lane. Improvements in engines for obtaining motive power by means of steam, air, gases, or fluids. (A communication.)

1057 H. Jones, jun., Soho-square, and W. F. De La Rue, Bunhill-row, Middlesex. Improvements in whist counters.

1058 J. G. Jones, Blaina Iron Works, Monmouthshire. Improvements in apparatus for hauling minerals in mines, and for raising water from mines and other places.

1060 S. C. Lister, Manningham, Yorkshire. Improvements in the manufacture of cut-pile fabrics.

Dated March 28, 1867.

1062 J. G. Fildes, Elton Bury, Lancashire. An improved bearer or support for conveying ladles containing molten metal.

1063 T. C. Currie, Kensington. An improved process for the preservation of milk.

1064 H. G. Warren and S. Stuckey, Deptford, Kent, and P. Froud, Greenwich. Improvements in revolving iron shutters.

1065 J. Macintosh, North Bank, Regent's Park, and W. Boggett, Lindsey Houses, Chelsea. Improvements in boots and shoes.

1066 C. Joyner, Birmingham, manufacturer. Improvements in water-slide gaseliers.

1067 J. C. Coombe, Charles-street, Holloway, chemist, and J. Poole, Riley-street, Chelsea, engineer. Improvements in coating iron and such like surfaces, and protecting them from the corrosive action of sea water, and the oxidizing influence of moisture.

1068 W. J. Addis, Tanna, Bombay. Improvements in the permanent way of railways.

1069 W. E. Gedge, Wellington-street, Strand. An improved apparatus for moistening postage and other stamps, to prepare them for application. (A communication.)

1070 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in filters. (A communication.)

Dated March 29, 1868.

1071 H. Armstrong, Tow Law, Durham, blacksmith. Improvements in the manufacture of steel and homogeneous iron.

1072 O. Ormrod, Eagley, Lancashire. Improvements in machinery for washing, bleaching, dyeing, and scouring hanks and cops of yarns and thread, woven fabrics, and other articles.

1073 C. F. Claus, Middlesborough-on-Tees, chemist. Improvements in the manufacture of iron.

1074 C. F. Claus, Middlesborough-on-Tees, chemist. Improvements in the manufacture of malleable iron, and in the process of re-heating the same for the purpose of rolling or hammering it.

1075 B. Mitford, Cheltenham, Gloucestershire. Improvements in apparatus for communicating with deaf and dumb or deaf or dumb persons.

1076 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of cast steel and malleable iron from cast iron, and in the apparatus or means employed therein. (A communication.)

1077 J. H. Johnson, Lincoln's Inn-fields. Improvements in the treatment of cork, and in the manufacture of a new compound or material therefrom applicable to various useful purposes. (A communication.)

1078 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of cast steel, and in furnaces to be employed therein, which furnaces are also applicable to the re-melting of metals generally. (A communication.)

1079 J. F. Hadland, Birmingham. Improvements in metal ties for securing bales of cotton or other substance. (A communication.)

1080 F. Wirth, Frankfort-on-the-Maine, Germany. An improved mode of, and apparatus for, stopping or retarding the progress of railway trains. (A communication.)

1081 J. M. Day, Trinity-square, Southwark, engineer. Improvements in decorticating seeds and oil nuts, and in the machinery employed therein.

1084 J. Walker, engineer, and J. Wharrie, foreman iron-founder, Glasgow. Improvements in apparatus for the manufacture of cast-iron pipes and similar articles.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated April 1, 1868.

1110 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for manufacturing horse-shoe nails. (A communication.)

Dated April 2, 1868.

1120 W. E. Boardman, Chancery-lane. A new and improved steam and water packing for use in packing stuffing boxes of steam engines, making joints, and other like purposes. (A communication.)

Dated April 3, 1868.

1128 C. W. Baldwin, Boston, Suffolk, Massachusetts, U.S. A new and useful device or instrument for measuring and registering the amount of a flowing liquid.

Dated April 6, 1868.

1159 C. Desnos, Chancery-lane. Improvements in the permanent way of railways. (A communication.)

Dated April 7, 1868.

1167 A. L. Holley, Harrisburgh, U.S. Improvements in the manufacture of iron and steel.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," April 14, 1868.

3413 J. C. Woolfield. Boilers for heating water.

3415 E. Price. Apparatus for regulating the supply of gas to burners.

3420 D. Barker. Constructing chambers for drying artificial fuel.

3241 W. Black and T. Hawthorn. Valves for steam engines.

3425 G. Breen. Steam winches. (A communication.)

3429 W. B. Leachman and J. Holroyd. Machinery for leather shaving.

3430 J. H. Wilson. Water-closets.

3447 T., G.B., and B. Stephenson. Waxing warps.

3451 E. T. Hughes. Cooking apparatus. (A communication.)

3456 J. F. Clarke. Means for melting snow.

3463 S. Perkins and W. Smellie. Manufacturing malleable metal.

3464 J. G. Scott. Means for effecting the safe transmission of money.

3466 A. C. Sterry. Engines worked by heated air.

3470 E. A. Pontifex. Condensers.

3482 P. R. Hodge. Machinery for heating and forming metals.

3484 J. B. Morrison. Construction of operating chairs.

3486 J. Blakey and H. B. Fox. Collars.

3492 R. Warry. Construction of breech-loading firearms.

3497 W. Clapperton. Machinery for shaping cask headings.

3498 W. Clark. Instrument for clipping horses.

3499 L. Rose. Preserving vegetable juices.

3509 J. Grout and E. Mathews. Apparatus for training hops.

3521 G. H. Nick. Pulley for ships' blocks.

3528 R. Roberts and P. Williams. Equilibrium slide valve.

3529 R. W. Brownhill. Water tuyeres.

3547 W. M'Ilwraith and J. Bonner. Apparatus to be applied to looms for weaving.

3566 A. M. Clark. Extraction of ammonia from fermented liquids. (A communication.)

3571 J., J., and J. Booth. Apparatus for dressing stone.

3577 W. H. Kerr. Preparation of material for manufacturing porcelain.

3587 E. M. Du Boys. Liquid meters.

3614 W. H. Richardson. Apparatus for manufacturing iron and steel.

3689 W. E. Newton. Butt hinges. (A communication.)

3690 W. E. Newton. Motors. (A communication.)

296 W. R. Lake. Pavement. (A communication.)

337 J. H. Johnson. Steam engines. (A communication.)

377 R. Morton. Refrigerators.

564 J. M. Kilner. Bedsteads.

599 W. R. Lake. Electrical signal apparatus. (A communication.)

677 C. E. Brooman. Moulds. (A communication.)

947 C. Mather. Apparatus for opening wool. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed April 9, 1868.

2846 C. Avery	2891 H. A. Bonneville
2849 A. F. Hobhouse	2912 J. Rives
2850 W. R. Lake	2917 G. M. Wells
2853 R. George	2929 J. Seward and H. Smith
2855 E. Haigh	2944 J. Schwartz
2857 J. C. Wilson	2955 J. Hunter
2861 A. Helwig	3033 C. E. Brooman
2868 J. Buckingham and J. S. Blockey	3123 A. V. Newton
2872 H. A. Dufrene	3129 H. A. Bonneville
2873 R. Canham and J. Thomson	3219 A. V. Newton
2878 B. Nicoll	3301 W. J. Murphy
2882 E. Ward	3359 E. Belknap
2883 W. Gadd and B. Walker	313 W. Guise
	464 F. Schafer

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

989 E. Welch	1046 T. J. Mayall
1024 S. Wright	1047 F. Bapty and E. B. Sayers
1026 D. Payne	1048 G. Jackson
1038 J. Haworth	1051 A. V. Newton
1039 H. Bridson	1077 A. W. Hale
1041 F. P. Warren	1104 D. Greig
1045 J. M. Hart	

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

858 H. Wilde	892 T. Don, T. Smith, and L. Horsfield
876 F. Taylor	933 R. Ransome
891 J. Lancelott	1009 E. H. Bentall
927 F. Gye

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, APRIL 24, 1868.

A CODE FOR UNIVERSAL BUOYAGE.

ON the broad highway of the ocean, where vessels of every nation on the face of the earth meet, it is a principle of the first importance that they should be able to intercommunicate with ease and certainty. To effect this, we have a code of signalling which is capable of being understood by all, no matter their nation or tongue, and which has been adopted as a universal language by all the great maritime nations. So far so good; but there is yet another matter closer inshore which demands serious attention. Every maritime nation has its coasts, ports, and harbours, and along and into these, vessels of other nations are perpetually passing. In their course they are beset with risks and dangers, and, therefore, here a simple and universally understood code of laws is demanded. This, in the shape of a uniform code of buoyage, would complete the great service rendered by the commercial code of signals to which we have alluded. This completeness, it may interest our readers to know, has been effected by Captain E. J. Bedford, R.N., who has designed a code of buoyage, which, upon careful consideration, appears to us to embody the three points necessary to recommend it for universal use. It is simple, inexpensive, and of universal application. The principle of the code is uniformity of colour, two only being employed—red and black, with a neutral white. The rule to be observed is, that a vessel entering a port, or approaching a centre, shall have all red, or red and white buoys on the starboard hand, and all black, or black and white, on the port hand, and *vice versa* on leaving port. The two colours blended, and either with or without white, may be passed on either hand. The only exception to these simple rules is the "fairway" buoy, which must be conspicuous both in shape, colour, and lettering. Captain Bedford has displayed great ingenuity in varying the arrangements of these three colours into different patterns and devices, so as to convey such further information as the peculiarities or special dangers of the channel may render desirable.

Now, this is the whole sum and substance of the arrangement, and one more simple, more easily comprehended and remembered, it is difficult to conceive. This code is adapted to seamen of all nations and languages, who would all equally appreciate the language of colour addressed to the eye. Not only has this system its own inherent advantages, which we have pointed out, but it is in accordance with that established for the coasts and channels of the sea by the United States of America (between which and this country there is so great a commerce), and also over the whole of Scotland, and at Liverpool, and other places. Hence it is extremely desirable that this system should be universally adopted, so as to reduce to a minimum the great risk and loss to life and property which are incurred at present from the confusion and uncertainty created by the want of an uniform system of buoying. We understand that the primary features of Captain Bedford's system have been adopted by the Commissioners of Northern Lighthouses in Scotland, and over several parts of the British coasts, also along the shores of the United States and some of the continental seaboards. We cannot help thinking how much anxiety and trouble might be spared were its adoption universal. What an assistance it would prove to a vessel in distress, perhaps disabled, in approaching an unaccustomed haven on a foreign shore. In the face of all this, we were quite prepared to learn that our authorities at home had done their utmost to promote its general use. But what was our astonishment to find that the Trinity Board object to the plan. For such a sapient brotherhood to object ought to mean something serious, thought we. So we looked into their objections, and found them to consist chiefly in a dislike to the particular colours which Captain Bedford advocates, and which are black, white, and red. Now, what on earth can it matter what colours are used, so that they are kept clean and made readily distinguishable? But we don't believe in these objections. The elder brethren raise a difficulty about distinguishing between the two chief colours. With respect to this, we can but regret in the interest of navigation a result which must retard any universal system.

But what is the state of the case? Why, that Captain Bedford has accumulated information from places where these colours have been longest in use, and that none of it tends to show that this difficulty has been experienced. Neither does he find that any injurious result has occurred from the use of them in juxtaposition. His own experience is that red more generally fades to white, and an authority upon this matter states that the only colour for which he considers red could be mistaken is white. The Commissioners of Northern Lighthouses have had Captain Bedford's system in use throughout Scotland for the last ten years, and since it was put in practice they have not received a single complaint either against the principle or the colours. Here is the highest testimony to the efficiency of the system. So, with all deference to the opinions of the Trinity Board, we cannot think otherwise than that the grounds upon which the elder brethren condemn Captain Bedford's proposition, and ascribe to it "grave errors," are unsupported by facts. Indeed, the objections really appear trivial and petty, and quite unworthy either of the sense or dignity of the Board. But we will hope better things of them, and trust they will be induced to listen to the memorials which they have received from various parts praying the adoption of Captain Bedford's system. At any rate, they ought to remodel the buoys in the Bristol Channel, for since these have been altered in conformity with the system of the corporation, vessels entering must leave upon the starboard-hand, black buoys and red ones; upon the port-hand, black and white, and red and white; and upon either hand, red, black, and white, and red and white; so that the navigation is entirely dependent on a local knowledge of the buoys. The local pilots confess to a difficulty here, and if this be so what must be the case of a stranger?

The whole sum and substance of the matter is that we have now before us a system resulting from the labours and observations of a hard-working practical seaman, who has spent the best part of his life in the hydrographic duties of the Admiralty. This system is at once simple, economical, and comprehensive, and the only thing to be desired is its general adoption. This the Trinity Board, either from a short-sighted policy, or from interested motives, at present refuse to sanction, as far as it is concerned. The keener northerners were by no means so slow to appreciate its value and to avail themselves of its advantages. Let their testimony convince the slower brethren, and stimulate all those who are directly or indirectly interested in the question, to petition, memorialize, and agitate until the great and dangerous roads along which the ships of our royal navy and of our mercantile marine travel, be marked and rendered so plain for safety that none can mistake their course. The advantages of Captain Bedford's system are so palpably capable of promoting this end that, in spite of all opposition, we predict that the time must come when the gallant officer will one day be universally acknowledged the benefactor of his race in having designed a practically successful uniform international system of buoyage.

AERIAL LOCOMOTION.

IN our last number we endeavoured to show that a new means of propulsion should be sought for, if travel in mid-air is ever to become general. It has been well observed that there does not appear to have ever existed a flying megatherium or a winged leviathan. Now, it must be evident that what is adapted to the movements of even the largest bird would not be suitable to move a whale on the wings of the wind! Why, to move the "Great Eastern" through the water it was found requisite, or, at all events, advantageous, to unite the principles of the paddle and screw combined. In Nature itself we find different means adopted according to size and requirements; for instance, if men were furnished with limbs as long, in proportion to their bodies, as grasshoppers enjoy, we might have been at Magdala or, for the matter of that, at Debra Tabor, a month ago; but how could the leverage of such lengthy legs be wielded on a large scale without herculean strength? James Watt tried to make a rotary steam engine, and succeeded to a certain extent, but he abandoned the plan because it was too complex, not easy to work, and liable, from the very nature of its machinery, to get out of order, for the simple reason that steam does not exert its force in a given direction only, like a blast of wind, but acts equally in every direction; therefore, if in any given sector of a circular space steam be introduced, it will neutralize its own strength, unless its pressure bear upon some extraneous diaphragm, which must be moved out of the way at every revolution to let the rotating piston pass. This introduced an element of constant complication which required intricate machinery, so that he very wisely obtained the desired result by a totally different means, viz., by the back and forward motion of the piston in a straight cylinder.

But if we suggest the adoption of some new method of propulsion, we are of opinion that something of the general form of a bird should be retained in the aerial machine, for, whatever its size, it must be of the shape best adapted to be forced through the air, and that may be calculated, although upon different data, as easily as the section of cutwater or of a ship. What can be more unsuited to move through the air than our present form of balloon, with the car suspended beneath it? In fact, it could not be moved through the air with any velocity at all worth speaking of, even with the strongest and lightest machinery that could be made and that it could carry. We may say that a breeze, with a velocity of four miles per hour, would carry the balloon with it in spite of any known motive power and machinery we could put to work in the balloon to resist it, or travel in a contrary direction. The velocity in any direction in a still atmosphere would be so small that we may practically call it *nil*. The surface to be pushed against the atmosphere is so great that a very small velocity would give enormous power. And the balloon could never carry sufficient power to be of the slightest practical use. To us it appears that the model aerial machine should be made somewhat of the shape of an egg, only more pointed; this machine, being built like armour-plated vessels, with a double skin—only not of iron plates—and then between its interior and exterior sides a suitable aeriform fluid, or something that would do away with gravity, should be introduced, by which sufficient buoyancy should be given, the space allotted to the flotation fluid being regulated according to the size of the machine.

Digitized by Google

We have often seen men walking through the streets with several small bladders filled with air attached to strings. Well, a number of these might be fastened together sufficiently large to hold two men so as form a model of the required shape, and experiments might then be made in the first instance with what we might then term a kind of "aerial pontoon." Indeed, it seems to us that aerial flotation might be used in many ways:—Firstly, in sustaining bridges, which, in very many cases, would enable us to reduce their cost and increase their span. Secondly, by raising vessels temporarily in the water; and this, we think, might be specially useful in the case of armour-plated vessels, so as to give them better water-lines while sailing. Then, the gas or air being discharged, they might settle down to fight, and could be again raised by inflation when about to pursue their way again over the waves. In any case, what we want now is to obtain data on which to base the theory of a convenint traction engine. And an aerial egg-shaped ship might be built in the manner described, which would be sufficient for preliminary experiments; or, it might be constructed with hollow steel stays and air-tight leather skins. Such a pontoon might be attached on either side to horizontally-stretched cables with rings at the ends free to run along parallel ropes raised on poles in the air. The ropes would act as rails, so as to prevent the experimental air-locomotive from rising too high or falling too low, and would prevent its capsizing until some steadying power be adapted to act as a keel does to a vessel. As the wings, or tail, or legs, or, all together, serve to enable a bird to keep its proper position during flight, perhaps a horizontal float made like the vanes of a windmill placed round the periphery of the egg-shaped windship might give it the necessary hold upon the air, so as to enable it to float without being overturned. To describe our meaning more clearly, it would then resemble in appearance the planet Saturn with his ring, only that the oval ring would be attached by an almost imponderable web to the elliptical or ship-shaped balloon. If we could but find the aeriform fluid that would do away with gravity, such a model aerial traction engine could be easily constructed, and it might run a mile or so in leading strings attached to rope-rails. With such an arrangement, most useful information might be gained to guide us further in our progress towards aerial voyaging, and give us what we now want—data upon which to proceed.

PHOTOGRAPHY IN THE PRINTING PRESS.

NOW that the public are becoming fully aware of the necessity of obtaining photographs which will not fade, all processes which will produce likenesses and pictures with ordinary pigments without sacrificing the truth incidental to good photographs, are of interest. A large establishment has just been fitted up at Brompton, under the management of a company, headed by M. Disderi, to produce pictures by Woodbury's carbon process. The beautiful transparencies upon glass, representing different members of the Royal Family, which within the last week or two have begun to make their appearance in the shop windows of our leading philosophical instrument makers, were issued from the afore-mentioned new works, which we have just visited for the purpose of collecting information for the benefit of our readers.

Many years ago, Mr. Mungo Ponton, F.R.S.E, discovered that gelatine impregnated with bichromate of potash, and then exposed to light, became insoluble in hot or cold water. This discovery was afterwards applied to practical photographic purposes. Colouring matter, such as Indian ink, was mixed with the gelatine and bichromate solution, some of which was then painted over a sheet of white paper and dried. The prepared sheet was then exposed to light under a negative, and afterwards soaked in warm water. Where the black film had been protected from light by the negative it dissolved away in the water, exposing the white paper beneath to view, but where the light had acted and made the gelatine insoluble, the black film would not dissolve. Thus a picture in black and white was obtained, but the "half-tones," that is to say, the most delicate shadows, were lost, and the picture had consequently a coarse appearance. The half-tones were lost in consequence of the thickness of the gelatine film, which permitted a perfect picture to be formed where the film touched the negative, but not where it touched the paper. In fact, supposing half the thickness of the film to be rendered insoluble because of the half-tones in the negative, the remaining thickness of the film would still be soluble in water, and when it dissolved therein would of course detach the delicate shadows above from the white paper beneath. In later times it was sought to obviate this defect by printing from the back right through the substance of the paper. As this stopped a great deal of light, mica and other transparent substances were tried in place of the paper, but it was necessary that these substances should be excessively thin. At last the first portion of the manipulations in the Woodbury process were discovered, whereby an infinitesimally thin film of collodion only intervenes between the negative and the pigment.

In this carbon process, as it is now worked, a plate of glass a little larger than the negative to be copied is well cleaned, and then, by means of a tuft of cotton-wool, rubbed over with a few drops of a thick solution of white wax in ether. The plate is polished with cotton-wool till it is quite bright, but an infinitely thin film of wax still remains upon it, and permits the collodion afterwards poured upon the plate to be removed from the glass without tearing in a later stage of the process. The plain collodion, which is next employed to coat the plate, dries upon the sheet of glass as an invisible transparent film. The gelatine solution has then to be applied, and it consists of one part by weight of Nelson's "amber" gelatine, dissolved in four parts of warm water, three per cent. by weight of bichromate of ammonia being then added to the solution. This addition must be made in a room illuminated by yellow light only, as the salt makes the solution sensitive to the action of actinic rays. Mr. Woodbury says that bichromate of ammonia acts better than bichromate of potash. The glass plate having been placed upon a levelling stand to keep it in a horizontal position, a thick pool of the warm viscous liquid is poured over it, which liquid has previously been coloured by the addition of a little blue pigment. The solution soon sets, and then each plate as prepared is put away horizontally to dry in grooved boxes fitted at the bottom with lumps of freshly-burnt lime. When dry, four broad lines, together forming a square, including a space the size of the picture to be copied, are painted on the film with black varnish.

When the film is dry, it is cut through all round near the edge of the plate with a penknife, and one corner is gently raised from the glass. This corner is then seized with the fingers, and the whole sheet, collodion and all, peels gently off the plate, without tearing. The film is then placed in the printing frame, with its collodion side in contact with the negative, so that the picture is printed through the collodion. To be quite independent of the aid of the sun, the electric light is employed in the printing operations, and is obtained from one of the new induction machines made by the Alliance Company, of Paris, and driven by a Lenoir's gas engine. A number of frames to hold the negatives are arranged at right-angles to the plane of propagation of the light, but some of these frames are nearer to the light than others, because with a hard dense negative the best pictures are obtained when a strong light is allowed to act for a short time. Weak thin negatives are best printed in a feebler light acting for a long time. Analogous phenomena to these have been noticed in all photographic printing processes, but the causes thereof are unknown, and it is very remarkable that a strong light acting for a short time does not produce the same photographic effect as a weak light acting for a long time.

After exposure to light the film is floated, collodion side downwards, upon a solution of india-rubber in benzole, and then dried. A sheet of white paper is likewise floated upon the same solution and dried. Then the film is laid upon the sheet of prepared paper, so that the two surfaces of india-rubber touch, and the two sheets are pressed into close contact by rolling with a ruler, after which they adhere with tolerable firmness. The edge of the film is next painted round with a little shellac varnish. The film having been thus firmly supported by a paper backing, is placed in tepid water, the heat of which is then raised very slowly, till in an hour it is nearly boiling. If the water be applied at a boiling temperature in the first instance, it seems to make the gelatine insoluble. The longer the original gelatine solution has been prepared, the longer must it be left in the warm water to develope a good picture. The water dissolves away the film where it has been acted upon by light, and the picture then stands revealed, the shadows being formed by different thicknesses of insoluble gelatine, holding blue colouring matter in suspension.

Up to this point the operations strongly resemble those used in Swan's carbon process, but here they diverge widely. The shadows in the picture thus obtained stand out in relief from the whites, and Mr. Woodbury discovered a method of obtaining a cast in metal of the indentations and elevations of the dried gelatine picture. A sheet of metal, consisting of lead alloyed with six per cent. of antimony, is laid upon a block of polished iron, with a mathematically true flat surface. The dried gelatine proof is laid upon the sheet of alloy, and then a second flat slab of polished iron is brought down by hydraulic pressure upon the whole arrangement. The result is that all the irregularities upon the film of gelatine are impressed in the lead, and, strange to say, the film is none the worse after the operation is over, but may be used again. It is also somewhat curious that it does not matter which side of the gelatine film is placed in contact with the lead, except in very delicate work, when contact with the wrong side of the film results in scarcely perceptible loss of sharpness. This pressing operation should not be done in damp weather, if it can be helped. The film and lead should be left under pressure for about three minutes, otherwise the elasticity of the metal will aid it to partially regain its original form. When the film is taken out it generally exhibits strongly electrical properties.

The metallic mould thus prepared is ready for the printing operations, but as its surface consists of slight hollows of different depths, printing ink cannot be used. The ink must be partially transparent, so that the thicker the ink the darker will be the shadows of the finished picture. Accordingly, the ink is made of colouring matters dissolved in a solution of gelatine, which solution, at a temperature of 175deg. Fah., is slightly viscous. We saw it worked at this temperature last Monday, the heat of the flasks holding the solution being kept up by hot water apparatus. The cold mould is placed, face upwards, on the base of the press, then a pool of the coloured pigment is poured over

Digitized by Google

its centre. Next, a sheet of clean white paper is laid upon the pool, then the pressure is brought to bear, and squeezes the gelatine all over the mould, as well as all over the paper in contact therewith, the surplus solution escaping at the sides. The handle of the press is held down by a catch, and the gelatine takes from one to five minutes to set, according to the temperature of the air. It is then taken out of the press. The mould is rubbed with a little salad oil, after each fourth or fifth picture has been taken. A dozen or two of these presses are kept at work to economise time. In the next operation the prints are soaked for five minutes in a saturated solution of alum, which transforms the gelatine into a leathery substance, insoluble in water; then the prints are washed well in water, dried, the rough edges cut off, and the finished pictures mounted on cardboard.

The paper on which these pictures are taken is specially prepared for the process, it being treated with lac, and afterwards rolled, to give a surface as hard and as much like glass as possible. As to the finished pictures, there is apparently no limit to their durability. The pigments used are Newton's transparent colours, as sold in tubes. If these change (and transparent reds and blues are not usually very durable), the black portion of the colouring matter is not likely to alter. Therefore, as regards the durability of the picture, the practical question at issue is, how long will a thin film of gelatine last when it is painted upon paper, and changed into leather by the action of alum. Evidently, it throws the present silver prints quite into the shade in the matter of permanency.

The very beautiful transparencies produced by this process are simpler to complete than the prints upon paper. A pool of the gelatine pigment is poured upon a mould, and then a sheet of glass, free from all traces of grease, is pressed down upon the mould with the fingers. The eye can see what is going on through the glass, and when it is seen that sufficient pressure has been applied, the whole is left for a few minutes to harden. Then the plate with the picture attached is taken off, is soaked for five minutes in the alum bath, is well washed in water, and is finished. Thus the colouring substance forming the body of these pictures resembles a thin film of leather. If these pictures were further screened altogether from contact with the atmosphere, and from scratches, by cementing another sheet of glass over them by means of Canada balsam, a still further guarantee of durability, and freedom from injury, would be given.

This process is patented, not only in England, but throughout the greater part of Europe. Already great preparations have been made in France to produce pictures by its aid, and Mr. Woodbury has just returned from Austria, where it also is to be brought into commercial operation. At present, the only establishment actually at work is the one at Brompton. There are two other carbon processes now at work in England, one, the invention of Mr. Swan, and the other, the invention of Mr. Pouncy, but neither of these call the printing press into operation. Mr. Swan and his coadjutors are producing permanent pictures commercially, but Mr. Pouncy is not doing so on any large scale.

Permanent photographs are the crying want of the present age, and the want is now on the point of being met by the above two or three patented processes, and probably by others of a promising character now under experiment. If these new processes make headway at a rapid rate, it will be a very serious thing for those photographers who stick in the old groove, so that the intelligent portion of the photographic community would do well to educate themselves practically in some of the permanent processes before they find the ground cut away from under their feet. One very pleasing feature of the establishment so freely thrown open to our inspection by Mr. Woodbury, is the department for the production of transparencies. Transparencies are the most perfect and delicate pictures producible by photography, and when good transparent likenesses are turned out on sufficiently moderate terms to suit the public, such pictures are likely to become "the rage," and to cause a demand like that experienced for cartes de visite some years ago. Already, there is a run upon the Brompton establishment for the transparencies of the members of the British royal family.

A NEW METHOD OF PRODUCING MAGNESIUM.

OUR chemical contemporary reports in its "Foreign Science" a new process of preparing magnesium, by M. Reichert. He takes 1,000 grammes of the anhydrous double chloride of magnesium and potassium, pulverizes it, and mixes it with 100 grammes of finely powdered fluor spar. This mixture is fused with 100 grammes of sodium, which reduces the magnesium chloride, or, at least, a part of it. Now, we should like to know wherein this differs from Deville and Curon's process, except slightly in the proportions of the ingredients. Deville and Curon make a mixture of—

Anhydrous chloride of magnesium	6 parts
Sodium in fragments . . .	1 ,,
Fluoride of calcium	1 ,,
Chloride of potassium . . .	1 ,,

This mixture is thrown into a red-hot crucible, and instantly covered. When the fusion is complete the mass is stirred. After cooling, the crucible is broken and globules of magnesium are found, which are agglomerated by fresh fusion. Here the sodium displaces the magnesium, as it must do in M. Reichert's. The chloride of potassium forms a double chloride with the magnesium, which is more easily acted upon than the single chloride of magnesium. M. Reichert simply forms his double chloride of potassium and magnesium first.

The fluoride of calcium is said merely to facilitate melting, which, we suppose, is the same in M. Reichert's process. In fact, the reaction in the two cases would appear to be identical, the only difference appearing being the different proportions of the ingredients. M. Reichert takes ten parts of the double chloride of magnesium and potassium to one of sodium and one of fluoride of calcium, and Deville and Curon take six parts of the chloride of magnesium and one part of chloride of potassium—that is, seven parts of the chlorides to one of sodium and one of fluoride of calcium. Now, since it is the sodium that displaces the magnesium in this reaction, we should like to know what difference there is in the two processes. The only difference we can see is that there will be a little more of the chloride of magnesium unacted upon in MM. Deville and Curon's process than in M. Reichert's. Does this constitute a new process? We cannot see that it does.

THE INSTITUTE OF NAVAL ARCHITECTS.

IN resuming our notice of the interesting papers read at the annual meeting of the above institution, we will first notice two papers upon tonnage. The first of these was contributed by M. A. Dekke, of Bergen, a member of the Norwegian Commission appointed to examine into the English system of measuring tonnage with a view to its introduction into Norway; the second, by M. Eugene Flachat. The object of M. Dekke's paper, was to lay before the naval architects of this country, assembled at their annual meeting, a comparison of the rules adopted in Norway for the measurement of ships, and those adopted in England. He hoped to be able to introduce the English method into Norway, but he thought the introduction would be facilitated if the English naval architects would recognize, and consent to, certain improvements which he proposed, namely, the use of fewer stations for the calculation of areas than are at present used. While, under the system now used in England, ships of lengths less than 180ft. are divided into four, six, or eight parts, M. Dekke would have all ships of 150ft. and under divided into four parts only, and all ships of 250ft. and over, into ten parts only. A table was furnished of the calculations as applied on the different English rules to six or seven existing Norwegian vessels of different builds, but we cannot enter into that here. The meeting declined to lend its sanction to the alterations proposed by M. Dekke.

M. Flachat's paper touched more upon the effects of the restrictions virtually imposed upon the forms of ships by the present methods of measurement. Tonnage dues have given rise to the rules for calculating tonnage, which, at present, is what mathematicians would call a function of the three variables—the length of the vessel, its beam, and its depth. Certain deductions are made for engine room and coal bunkers, and also for the accommodation of the crew. How far any of these deductions is desirable is very questionable; but neglecting them, this question of tonnage in itself has seriously affected the form, and also the safety of ships. A ship of 5,000 tons displacement, built for passenger traffic, might have a freeboard of 12ft. and a volume of 9,000 tons, while a ship of the type of the unfortunate "London," built for goods traffic, with the same displacement, would have a volume of only 6,500 tons, and a freeboard not half that of the other vessel. The former is safe in a heavy sea, which breaks over, and after carrying away the hatchways, at last swamps the latter. But why this difference between the two ships? It is the consequence of the tonnage law. The luggage boat cannot afford to pay the same dues as the passenger boat; its tonnage is, therefore, decreased for economy's sake, without regard to safety. If the foundering of the "London" can be put down to the score of the present law, as there really seems some reason to believe, the sooner that law is changed the better. M. Flachat proposes that tonnage should be made a function of one variable only—the length of the vessel. We cannot agree with him in this; as we believe as much would be laid to the charge of the new law, if this change were made, as is now laid to the charge of the present law. Why should not different methods of rating be adopted for different classes of vessels? It is not the practice for railway passengers to pay their fares by weight, nor do goods pay exactly in proportion to the distance they are carried. If one method be used for all ships, it seems to us that value is the only fair basis for all dues to be reckoned on, and to thwart all frauds by undervaluation, the ship should be liable to be purchased by Government at the price at which it was valued. The same rule might be applied to insurances of all kinds, the option of purchase resting with the insurance office in each case.

We now come to a very different subject—the testing of iron by magnetism. What the mysterious connection between iron and the magnet is, may never be discovered, but we are already well acquainted with some of its results, and have learnt to subject them to our use. Electricity, magnetism, and the kindred sciences, are still only in their infancy, yet we have made of the infant a giant in bearing our messages, to the annihilation of both time and space. The oldest form of service which we derive from magnetism is, as all well know, in the mariner's compass. This has, however, of late been severely tested in the case of iron ships. The compass was, in them, so much affected

Digitized by Google

that it was feared that the "guardian angel" of old England's wooden walls was to become the "destroying angel" of her iron ones. Such and so great is the sympathy existing between the magnet and iron in every shape, that we cannot but feel that in some subtle form they claim and find a kindred in nature or origin. In Mr. Saxby's investigations into the character and condition of iron forgings, &c., by magnetism, he has probably only discovered (if his theory be ultimately proved sound) some scattered and obscure fibres of the, so to speak, umbilical cord, which unites parent and child, cause and effect. Confessedly, no great discoveries have yet rewarded Mr. Saxby's researches, but we think he need not despair. What he has found should stimulate to further inquiries. The sparks of light which gladden him from the darkness may fail, it is true, and prove only an *ignis fatuus*, but, on the other hand, such sparks have, ere now, led to paths of light in the regions of science. If breaks of continuity in the goodness and condition of masses of iron can be detected by the simple application of a magnet to them, no doubt much danger will be avoided, much expense saved, and a greater degree of safety be secured in the uses of man's best servant in the mineral world. The evils consequent on the present modes of testing work of all sorts will be got rid of. Who can say how many girders have snapped when placed in position from the injury caused by testing—how many lives been lost by the bursting of guns which had received their fatal flaw in the "proof house?" As we have said, Mr. Saxby's experiments are yet too limited in extent and result to enable us to hazard an opinion as to their final issue, but we think he has shown enough to encourage him in the path on which he has entered; nor shall we be surprised if next year he has some further fruit to exhibit under the influence of the motto *Nil Desperandum*.

A paper by Mr. Arthur Rigg, jun., was read on the subject of the reverse currents and slip of screw propellers. This is a subject on which so much has been written, and of which, nevertheless, so little is understood, that we are always inclined to shudder at the mere mention of slip, especially negative slip. We think that it is a pity that all attempts to explain—or to further confuse—this subject are based on the action of the screw. Why should not more observations and calculations be made as to the slip of paddle-wheels, seeing that the action of the floats of the paddle on the water is of so much simpler a nature than that of the blades of the screw? We quite agree with Mr. Rigg in his remarks on what we may call the aberration of the water thrown off by the blade of the screw. Each particle of water (neglecting friction) is projected in a direction at right-angles to the surface of the blade which strikes it. If a vane could be fixed in the water close behind the screw at any instant, it would, no doubt, give the actual direction of the current thrown off by the blade. If, however, the vane be attached to the ship, the direction it will take will be, not the actual direction of the current, but the direction of the current relative to the vessel.

Mr. Rigg has not, in our opinion, been so successful in expressing his meaning when he speaks of the action of the blade of the screw on the water. He represents the "total work" of one revolution of the screw by a straight line, part of which he supposes to represent the "reverse current," and the remainder the "coincident advance of the screw and the ship that is being propelled." Unless we are mistaken, Mr. Rigg seems to think that no work is expended in giving motion other than sternward to the water, while, under the term "reverse current," it does not appear whether we are to understand merely a velocity or a definite mass of water moving with that velocity. However, Mr. Rigg goes on to apply his theory (which he, no doubt, has clearly imprinted in his own mind, though it is not so manifest to the eyes of his readers) to a few examples. He gives us a few figures showing the difference for three different screws in the two cases of a ship steaming alone and towing a barge. He considers that the "closeness" of the results obtained from calculation and from observation is presumptive evidence in favour of his theory; but, as in one out of his three instances, we find that, for the vessel going alone, the observations gave 25deg. in place of 20deg. obtained from calculation, while, for the vessel towing a barge, the observations gave 31deg. and the calculations 39deg., we would advise him not to lay too much stress upon the closeness of the results, nor, in consequence, on the truth of his theory. Mr. Rigg refers to the absurd notions some persons have on the resemblance of the screw's action on water to that of a corkscrew on its subject cork. The persons who hold this opinion, obtain the speed of the ship by the simple process of multiplying the pitch of the screw by the number of revolutions, and, although we can afford to smile at their simplicity, we cannot allow, with Mr. Rigg, that the assumption of the advance of the ship's being due to the pitch is unsound. Mr. Rigg tells us that, with a screw with 3ft. pitch, there was a positive slip of 7¼ per cent., and an advance of 33¼in. per revolution, while, with the same screw, with a pitch of 2ft., there was a negative slip of 4½ per cent., and an advance of 25in. per revolution. These results indicate, we are told, the loss of power well known to accompany negative slip. We are far from considering them as conclusive indication of this or anything else, unless we are told how many revolutions were made in a minute, and what the indicator diagram evidenced in each case.

A paper of very considerable importance was read by Captain E. J. Symonds, R.N., on the subject of fixed central batteries. Now that millions after millions are being voted by Parliament for the rehabilitation of our navy by iron and steel armour, it is of the greatest importance that the best principle of application should be ascertained. Shall the ships which are hereafter to defend our coasts at home, or win our battles abroad, have their coats of mail equally distributed over their whole surface, or over those parts only where damage would be most detrimental or fatal? That is the important question here discussed by Captain Symonds. It is manifest that, if "central" batteries alone be used, then the heavy iron plating may be confined to that part of the ship, provided the water line be, in addition, effectually protected. For, if the ships be built with well-secured water-tight compartments, a shot in the non-vital parts would be comparatively innocuous. But before we can decide o limiting our naval batteries to this central position, we must show that the guns there placed could do execution in all directions—with end-on fire as well as broadside. For if a ship be able to fire effectively in one position only, it is clear she must be for a considerable portion of her time when in action more liable to receive injury than adapted to inflict it. Now, Captain Symonds shows that ships carrying only central guns can render good service through nearly the whole circle. This point, then, being established, it follows that no need exists for forecastle batteries, and the heaviest armour need not be used on this part of the ship. In this way we are shown how to construct vessels able to sail safely as well as fight effectively, which is impossible with "complete protection." The "Warrior," which has only central protection, still stands pre-eminent for her sea-going qualities, both in her form and handiness, affording a happy model for what a large class of our ships of war should be.

Following Captain Symonds through his several examples of vessels now afloat, and assuming that he has fairly stated their performances, we see but one conclusion to draw—viz., that "central batteries are the most efficient (for they may be made effective end-on as well as broadside) and they are least liable to injury from the enemy's fire (since one central battery has far less exposed surface than two or more distributed). Also, such ships are more steady and more easily fought, being always clear and ready for action. The old "hurry-scurry" of getting everything heavy amidships on sighting an enemy could no longer exist, as it would be all done beforehand, and in the case of forecastle batteries could not be done at all. In nearly every way, then, we see but good in Captain Symonds' suggestions.

Mr. "Rob Roy" Macgregor presented himself to the meeting, and gave a *viva voce* description of certain improvements which it had occurred to him to make in the compass. These were the result of experience acquired during a voyage of several months in a yawl manned by himself, and christened "Rob Roy" out of respect to his faithful canoe, the cruises of which are so well known to and appreciated by an adventure-loving public. One moiety of the profits arising from the sale of Mr. Macgregor's accounts of his canoe voyages was, by his kindness and liberality, handed over to the Lifeboat Institution, who, as a slight acknowledgment of benefits received, presented the author with a "liquid boat compass," a kind with which all their lifeboats are furnished. This compass Mr. Macgregor used during the summer and autumn of last year on board his yawl, and had ample opportunities to find out its defects, and, being alone, ample leisure to ruminate over them. Apparently, those opportunities were not thrown away. Among other things, the size of the lamp and of the wick, the position of the wick, the introduction of air into the lamp, the colour of the card and its design, all received Mr. Macgregor's attention. The captain of the Canoe Club, who at one stormy period last August, was forced to keep his eyes open and fixed on his compass for more than fifty consecutive hours, is, as the noble chairman, the Earl of Hardwicke, an old sailor who is proud of his profession, justly remarked, "of all men the one most competent to appreciate the defects in the present compass, and most entitled to a hearing when he suggests improvements to remedy those defects."

Next in order comes a valuable paper by the Chief Constructor of the Navy, which, with other matters, we reserve for a concluding notice in our next number.

GENERATING STEAM BY GAS.

WITHOUT doubt gas is one of the greatest blessings modern times has produced, and fully as its value is appreciated, we believe its usefulness is not yet perfectly realized. But, by degrees, we are beginning to understand that it is not only a mere light-giving medium—though that itself were an inestimable boon—but that we can utilize it for the purposes of cooking, of driving engines, and of heating steam boilers. It is in this latter capacity we now have to notice it, and as applied to this useful and economic purpose by Mr. Arthur Jackson. It has often occurred to us how very greatly the carrying out of some provisions of the Street Traffic Regulation Act might be facilitated if those warehouses abutting upon our narrow public thoroughfares had their crane work effected more expeditiously. Not only would the thoroughfares be less liable to stoppages from loading and unloading goods, light as well as heavy, but the proprietors themselves would benefit by a saving of labour. Now, there are very few places where steam power can be applied, in its ordinary form of production, if even it could be tolerated. Then, again, the insurance companies, with their heavy

Digitized by Google

risk-premiums, meet the proprietor and fetter his actions. There is also the consideration of first cost and expense of maintenance ready for use while not engaged in actual work. But if there be the means of affording the warehouseman the full benefit of steam power, without incurring any of the foregoing objections, then we hold that a great step in advance has been gained. And this, in fact, is just what we meet with in Mr. Jackson's steam generator, which is heated by gas. It occupies but little space, and, placed in a corner of the top loft of the highest warehouse, it commands its work and is out of the way. Its first cost is not great, whilst its working expenses are very trifling. The insurance companies pass it without additional premium on their fire policies, and steam may always be kept with a mere jet of gas on—a very valuable feature considering the intermittent work hoists and cranes have to perform.

It is now more than a year since we noticed the first practical adoption of this system of steam generation by a large warehouse firm in London. Since that time, several others have followed the example, the latest being Messrs. Ledger, of Lyons Wharf, Upper Thames-street, upon whose premises an apparatus has just been erected, which we recently inspected. We found a vertical tubular boiler of 3-horse power supplying steam at from 50lb. to 60lb. pressure to drive a set of sack tackle for working four chains for unloading barges laden chiefly with grain. The boiler and engine are placed on the upper floor of the warehouse, and present a very compact and neat appearance. As a guarantee for the character and finish of the work, we may observe that the manufacturer is Mr. Middleton, of the Loman-street Works, Southwark. The gas is led beneath the boiler to a chamber resting on a stone slab. Vertical burners fitted with regulating cocks and air valves reach from the chamber nearly to the under side of the boiler, and this completes the simple arrangement. There are twenty-three burners in the present instance, and the consumption of gas is stated to be 100ft. per horse-power per hour in full work. Wherever these gas-heated boilers are at work, ample testimony is borne to their efficiency and economy. These are the two great points which proclaim the success of any system or invention, and we are glad to find them developed in Mr. Jackson's apparatus. With such a means of generating steam within easy reach, our wharfingers and warehousemen will certainly be consulting their own interests by adopting them.

NOTES ON OUR NAVY.

NOTES of mine, on the above subject, have appeared at various times in the MECHANICS' MAGAZINE, written in good faith and with a thorough knowledge of the subjects treated on. I now feel assured that my suggestions will in due time be carried out, as I can already perceive that many of the best officers in the service are favourable to them. The death knell of converted ironclads has been rung, and never again, except in some dangerous hour, will men recommend such costly experiments to be tried on wooden two-deckers. Not long since there were severe comments on the Admiralty for selling a number of them. I have no hesitation in asserting that the Board acted wisely by so doing, and saved the country an annual expense, which under present circumstances could be ill afforded. It is too much the fashion to abuse men in office for decisions which step out of the beaten track, for any one to wonder at such comments. In times like the present the naval rulers of England have quite enough work to do in trying to keep pace with the many ambitious powers which have sprung up around us, without keeping a lot of obsolete ships on hand to rot at their moorings, or fill up our harbours. Never since England was a great nation did she stand in such a critical position as she does at present. In former times she was enabled to stand defiantly by and regulate the peace of the world; that day has gone for ever, and we must now be content to keep our shores from invasion and our flag from insult. For this we require the best ships and seamen which can be had, and where are they? I look around and see them not, but in lieu I see a fleet of various dimensions armed with guns of the largest calibre, which cannot be worked in ordinary bad weather by many. Why are we so placed? Could not one ship of the "Royal Oak" class have been well tried before such a large number were taken in hand? Our seas are famed for their storms, and men-of-war which cannot keep them without inconvenience at all seasons should not be relied on by a people whose existence depends on their fleet.

There are those amongst us who have seen the "Lord Clyde" rolling her armour belting clean out of the water after a moderate gale. What an opportunity would be given to some daring seaman, who, in the event of a war, might come within range at such a time. Neither can I speak more favourably of many others. A paragraph recently appeared in the "United Service Gazette," stating that the officers of H.M.S. "Bellerophon" had refused to be responsible if she were manœuvered under sail only. Now in action it is an admitted fact that machinery may be disabled from many causes. A chance missile may damage the stern post and render the propeller useless; concussion of a heavy shot may break a rod or a pipe in the engine room, and then this much-vaunted ship would be helpless, if the published report be true. The ships of all nations are subject to such disasters, and the chances on that score would be equal, some one may say. True, yet Englishmen have hitherto believed themselves better able to handle ships under sail than the seamen of any other nation on earth, and the chances from such disasters should be wholly in their favour. There are other ships which can with difficulty be wore at all, and no man dreams of bringing one into port under canvas only. Is this, Sir, a correct position for the once great mistress of the seas to be placed in with navies springing up around her on every hand? The answer is obvious, and all true lovers of their country must look with anxiety on the future. The time is not far distant when England will be compelled to call in the distant outposts and concentrate her defences around her own shores. At the present day the position of the armament of the great majority of the colonies is unsatisfactory. In many I perceive huge twelve-ton guns lying about dismounted, like gigantic boulders in an ice-worn country, when the floods have subsided, and carriages rusting away without any shelter from the weather, and armour plating for forts without forts to put it on. At Gibraltar and Malta the shields will not resist shot, nor the greater number of the guns penetrate. Batteries, which were once impregnable, are now useless, so much has the whole system of warfare changed; and if we are determined to hold these places, we have much to do before they will reach the proud position they once held, and be able to bid defiance to the world in arms.

There cannot be a doubt that for all purposes of warfare a large ship, if properly built and rigged, is greatly superior to any number of small ones, carrying the same amount of guns between them, which can be brought against her; she carries her armament higher above the water-line, is swifter, better able to use the stem, and, what is of no little consequence in such matters, inspires he crew with confidence in her seagoing, qualities and powers of offence and defence. In a former paper I have given my ideas of the formidable nature of a vessel which could charge an enemy without the fear of foundering from the shock; there could be no divided opinion concerning the fate of her antagonist. But here the skill and daring of the seamen would be of equal importance to the science of the shipbuilder; any mismanagement of the former would render abortive the highest order of talent which the latter might possess, Second in importance to a ram are upper deck guns. I have no faith in the aim of the captains of guns through a narrow main deck port in the smoothest water; when smoke begins to fill the between decks or obscure the motions of an enemy, and in bad weather it is simply a waste of ammunition to attempt to fire. Again, main deck ports will occasionally be shot away, and under such circumstances the safety of the ship would be risked, because, to avoid an enemy, she might have to run in the trough of the sea at all risks, and Mr. Reed has probably never seen a main deck port stove in on such an occasion, or the alarm it creates. With all the admiration I have for his talents, I believe he could learn a few trifles by consulting practical men, for I feel no confidence in a ship which is not perfectly manageable under sail as well as steam.

Though perhaps out of place here, I cannot help commenting on a subject which appears hitherto to have escaped the notice of statesmen and the Admiralty. Russia makes no secret of her intentions to become a first-class naval power. Already she has secured a port which will make the North Sea accessible to her at all times. When completed it will be a standing menace to our shores incomparably more than Cherbourg, as we have not an arsenal or dockyard throughout the whole extent of the eastern shores of Scotland and England, nor a port where a disabled ship could run for safety. In the days of our grandfathers, Yarmouth Roads formed a sufficient shelter on most occasions for the fleet, but then ships required neither constant supplies of coal or repairs to elaborate machinery; neither could an enemy quit his port if the wind were adverse. Again, we have only to turn to the list of wrecks of the English Navy to perceive the fearful loss of life and property which this service entailed. The shores of Jutland and Holland were strewed with the corpses of English seamen and the shattered hulls of English ships, and at this day the traveller is shown the graves of his drowned countrymen on that inhospitable coast. Since that time science has done much to mitigate such disasters, but science could not keep a fleet cruizing in the North Sea without a better provision for a disabled ship than we have at present, or prevent a determined enemy from coming out on a dark, stormy night. I have cruized in that sea in peaceable times, and often have felt that it would be impossible to do it, and, with our present ironclads, folly to attempt it during the storms of winter. I have already given my views of the class of ships we ought to have, and in some future paper I shall enter more into details. Time will show whether I am only an alarmist.

X.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

USE OF BARYTA IN THE PREPARATION OF WOOD VINEGAR—A NEW AND EASY METHOD OF FUSING REFRACTORY MINERALS—VARNISH FOR IRONWORK.

SOME months ago, we called attention to a suggestion useful to the makers of wood vinegar, and that was the use of baryta in place of lime. It was said that acetate of baryta stood the torrefaction necessary to carbonize the empyreumatic matters very much better than acetate of lime, and the yield of acetic acid was consequently increased. We read however, that the torrefaction may be altogether dispensed with. When

Digitized by Google

a solution of acetate of baryta is evaporated to dryness with constant stirring, a very dense granular powder of a brownish-black colour is obtained. By washing this with alcohol, the empyreumatic matters which give the colour are dissolved away, and a nice white salt is left. The powder is so dense that a very small quantity of alcohol suffices for the washing. Wood spirit can also be used, and, of course, either can be recovered by distillation.

A process is given in the last number of "Silliman's Journal" which will rejoice the hearts of all analysts who have to examine very refractory minerals. Chrome iron ore, rutile, tinstone, and several other minerals, have teazed the chemist by the difficulty of getting them into solution. This difficulty, however, no longer exists. By the use of fluoride of sodium and bisulphate of potash either one of the minerals we have named can be completely fused in from three to five minutes, and, with the exception of tinstone, over an ordinary Bunsen's jet. Tinstone requires the addition of a blast, but with the help of this is fused in as short a time as the rest. In carrying out the process, one part of mineral is mixed in a platinum crucible with three parts of fluoride of sodium, and on the top of the mixture is placed twelve parts of bisulphate of potash, which may be in powder or small lumps. When the heat is applied, the mixture soon begins to boil, but as quickly settles in tranquil fusion. In quantitative experiments the crucible must be covered to prevent loss. It is not necessary to continue the heat for longer than five minutes. In most cases, the fused mass, when cold, will be found to be completely soluble in water; but in some instances a basic salt is found, which is soluble in hydrochloric acid. A second fusion, however, after the addition of a little strong sulphuric acid, will leave a mass completely soluble in cold water. We give a few special examples. Chrome iron ore fuses very easily, and need not be employed in very fine powder. The fusion is complete in three minutes from the first application of the heat of a Bunsen's burner. The cold mass is, for the most part, soluble in water, but entirely in hydrochloric acid. After a second fusion it is completely soluble in water. Hæmatite and hard specular ore are completely resolved. The mass is perfectly soluble in hydrochloric acid, and after a second fusion in water. In these cases, the iron being in the state of sulphate is advantageously placed for determination by permanganate. Tinstone, as we have said, requires the assistance of a blast. It gives a white mass which is almost entirely soluble in water. A small amount of stannic acid generally remains undissolved. A second fusion, with a little sulphuric acid, gives a mass quite soluble in water. If, then, the solution be rendered nearly neutral, leaving a slight excess of sulphuric acid, and any iron reduced by sulphuretted hydrogen or hyposulphite of soda, the solution, when boiled, will deposit all the tin as stannic acid. Tungstic, niobic, and tantalic acid, if present, will go down at the same time. Rutile and omery fuse very easily with the fluoride and bisulphate, and the mass is completely soluble in cold water. The same method may be employed with zircon and wolfram, but in the latter case is not so necessary, seeing that the mineral is soluble in nitric acid. The great recommendation of this method of fusion is the ease and speed with which it is effected. It has hitherto been necessary to apply the heat for an hour or two, and then, as the books usually say, "a little of the mineral will be left undissolved," which must be separated by filtration, and another fusion made with the same difficulty. In most cases the author tells us that ordinary cryolite may be used for fluoride of sodium, but it has the disadvantage of introducing alumina into the solution. Fluoride of sodium can, however, be prepared with even more ease than stated by the author.

Dr. Lunge gives, in "Dingler's Journal," a method of making an excellent black varnish for ironwork. He distils gas tar until nearly all the volatile products are got rid of. He then stops the distillation, and dissolves the residual pitch either in the heavier oils, or, if a very quickly drying varnish is required, in the light oils or naphtha. This varnish is, of course, the original tar minus the ammonia, water, carbolic acid, and other things which give it its disagreeable odour, and make it so long in drying.

INSTITUTION OF CIVIL ENGINEERS.

AT a meeting of the Institution of Civil Engineers, held April 7, Mr C. H. Gregory, President, in the chair, the paper read was on the experimental determination of the strains on the suspension ties of a bow-string girder, by Mr. W. Airy, Assoc. Inst. C.E.

Although in this communication the case of a bow-string girder, as ordinarily constructed, only was considered, yet the author believed that the principle on which the strains had been ascertained was equally applicable to all mechanical structures with complex bracing, as, for instance, station roofs, where the labour and uncertainty of a theoretical calculation rendered an experimental investigation exceedingly desirable. The model on which the experiments were made was composed of a bow of steel, and had a span of 6ft. with a rise of 1ft.; the string being constructed of two slips of oak, and the suspension ties being of steel wire, gauge No. 6 (96ft. to the oz.). The process by which the tensions were ascertained was the following: the ties, on being sounded, gave a good resonant musical note, and advantage was taken of this to compare the note of any string with that of a free string suspended in a frame, and cut off by a sliding bridge to the length of the string under comparison. The free string supported a small scale-pan, and this scale-pan was loaded with weights till the note of the free string and that of the string under comparison exactly coincided. This was determined by ear with the greatest accuracy, the effect of half an ounce in eighty ounces being clearly perceptible. The tension of the string on the girder was thus measured by the weight in the scale-pan of the free string; and this was done for every string in every case.

The determination of the thrusts was arrived at by a differential process, thus:—A uniformly distributed weight was applied on the girder, and the tension of every string was taken; then a travelling weight was introduced in addition, and hung at any one point, and the tension of every string was again taken: the difference of the tensions in the two cases of each string being regarded as the thrust, or tension, of that string produced by the travelling load. The reduced results of the experiments comprising the effect of every possible arrangement of loads that could come on a girder were given in diagrams. It was verified by experiment: 1st, that the tension, or thrust, of every string was proportional to the weight causing it; and 2nd., that when several weights were applied at the same time, the effect on every string was that due to the sum of the effects which would be produced by each of the weights separately.

The rules by which the strength of ties should be regulated, as deduced from the experiments, were, for an evenly distributed stationary load, that all the bars were in tension, that the end uprights were most strained and the middle ones least, and that, with respect to the diagonals, those were most strained which radiated outwards from the points where they met the string—the strain on each of which might be taken at one-half the load due to a bay—those that radiated inwards from the points where they met the string being strained to the extent of one-fourth the load due to a bay. In the case of a single movable load, the uprights were liable to a tension of from 10-34th to 1-6th of the weight, as the load advanced from either end towards the middle, and the greatest tension to which the diagonals were liable was one-fourth, and the greatest thrust two-thirteenths of the weight.

DR. LIVINGSTONE.

WE have much pleasure in placing before our readers the following extracts from a letter which was received last Monday, in Edinburgh, from Dr. Livingstone, by a friend of the celebrated traveller:—"Country of the Chipeta, Nov. 10, 1866.—It has been quite impossible to send a letter coastwise ever since we left the Rovuma. The Arab slave-traders take to their heels as soon as they hear that the English are on the road. I am a perfect bugbear to them. Eight parties thus skedaddled, and last of all my Johanna men, frightened out of their wits by stories told them by a member of a ninth party who had been plundered of his slaves, walked off and left me to face the terrible Mazitu with nine Nassick boys. The fear which the English name has struck into the souls of the slave-traders has thus been an inconvenience. I could not go round the north end of the lake for fear that my Johanna men, at sight of danger, would do there what they actually did at the southern end, and the owners of two dhows now on the lake kept them out of sight, lest I should burn them as slavers, and I could not cross in the middle. Rounding the southern end, we got up Kirk's range, and among Manganja not yet made slave-sellers. This was a great treat, for, like all who have not been contaminated by that blight, they were very kind, and, having been worried enough by unwilling Sepoys and cowardly Johanna men, I followed my bent by easy marches among friendly generous people, to whom I tried to impart some new ideas in return for their hospitality. The country is elevated, and the climate cool. One of the wonders told of us in successive villages was that we slept without fires. The boys having blankets did not need fire, while the inhabitants, being scantily clad, have their huts plastered inside and out, and even the roofs, to make themselves comfortable. Our progress since has been slow from other and less agreeable causes. Some parts have been denuded of food by marauding Mazitu or Zulus; we have been fain to avoid these, and gone zigzag. Once we nearly walked into the hands of a party, and several times we have been detained by rumours of the enemy in front. January, 1867.—I mention several causes of delay. I must add the rainy season is more potent than all, except hunger. In passing through the Babisa country we found that food was not to be had. The Babisa are great slave-traders, and have, in consequence, little industry. This seems to be the chief cause of their having no food to spare. The rains, too, are more copious than I ever saw them anywhere in Africa; but we shall get on in time. February 1.—I am in Bemba or Lobemba, and at the chief man's place, which has three stockades around it, and a deep dry ditch round the inner one. He seems a fine fellow, and gave us a cow to slaughter on our arrival yesterday. We are going to hold a Christmas feast off it to-morrow, as I promised the boys a blow-out when we come to a place of plenty. We have had precious hard lines; and I would not complain if it had not been gnawing hunger for many a day, and our bones sticking through as if they would burst the skin. When we were in a part where game abounded I filled the pot with a first-rate rifle given me by Captain Fraser; but elsewhere we had but very short rations of a species of millet called 'macre,' which passes the stomach almost unchanged. The sorest grief of all was the loss of the medicine box which your friend at Apothecaries' Hall so kindly fitted up. All other things I divided among the bundles, so that if one or two were lost we should not be rendered destitute of such articles; but this I gave to a steady boy, and trusted him. He exchanged for a march with two volunteers, who behaved remarkably well, till at last hungry marches through dripping forests, cold hungry nights, and fatiguing days overcame their virtue, and they made off with 'Steady's' load—all his clothes, our plates, dishes, much of our powder, and two guns, and it was impossible to trace them after the first drenching shower, which fell immediately after they left us. The forests are so dense and leafy that one cannot see fifty yards on any side. This loss, with all our medicine, fell on my heart like a sentence of death by fever, as was the case with poor Bishop Mackenzie; but I shall try native remedies, trusting Him who has led me hitherto, to help me still. We have been mostly on elevated land, between 3,000ft. and 5,000ft. above the sea. I think we are now on the water shed for which I was to seek. We are 4,500ft. above the sea level, and will begin to descend when we go. This may be put down as 10deg. 10min. south lat., and long. 31deg. 50min. 2sec. We found a party of black half-caste Arab slaves here, and one promises to take letters to Zanzibar, but they give me only half a day to write. I shall send what I can, and hope they will be as good as their word. We have not had a single difficulty with the people, but we have been very slow. Eight miles a day is a good march for us, loaded as the boys are; and we have often been obliged to go zigzag, as I mentioned. Blessings on you all. Love to Mrs. ———. From yours, ever affectionately, DAVID LIVINGSTONE.

THE inauguration of a statue of Bernard Palissy is to take place at Saintes, where the famous potter was born, on the 3rd of May. The fête to be given on the occasion will recall one of the most interesting events in the history of the town, namely, the entry of Charles IX. and Catherine de Medicis, and their visit to Palissy, whom they took with them to Paris, where he was installed in the old Louvre, and executed some remarkable works; and where the remains of his kiln and a number of his moulds were discovered last year.

ELECTRICAL TESTS OF RECENT SUBMARINE TELEGRAPH CABLES.

THE following tabulated statement of the Electrical Tests of various recent Submarine Telegraph Cables, which has been compiled and forwarded to us by Mr. Latimer Clark, C.E., will prove of practical interest to our telegraphic readers. We should premise that the Mil is the 1-1000th. part of an inch. The Megohm = one million ohms. The Farad is the standard unit quantity of electricity as determined by the Committee on Standards of Electrical Resistance appointed by the British Association; it is that quantity of electricity which with the unit electromotive force passes through a resistance of one Megohm in one second. The unit of electromotive force does not differ greatly from that of a Daniell's cell.

The inductive capacity of a strand is assumed as 5 per cent. less than that of a solid wire of the same diameter, and has been so allowed for in calculating the relative capacities. The following empirical data may be found sometimes useful for calculating the approximate weight of cores. 54 circular mils in sectional area of copper, 69 circ. mils of copper strand, 63 circ. mils of iron, 481 circ. mils of gutta percha, or 401 circ. mils of Hooper's material—weigh one pound per knot.

Hence $\frac{d^2}{54}$ gives the weight per knot of any solid copper conductor, and $\frac{d^2}{69}$ of any copper strand, and similarly $\frac{D^2 - d^2}{481}$ gives the weight of gutta-percha in any core. $\frac{d^2 n}{6789}$ gives the weight of iron in cwts. per knot (including lay) for any cable of n wires.

MUZZLE PIVOTING GUN CARRIAGE.

LAST Monday evening, Captain T. B. Heathorn read a very interesting paper on the above subject at the Royal United Service Institution. After noticing the advantages of the muzzle-pivoting system, he described his own invention. Early in 1865 he had been impressed by the fact that the facilities for working heavy guns did not keep pace with either their size or the anticipation of the results to be achieved by them, and he took to the study of the requirements as a new field of professional interest. He then constructed a carriage on the following resolutions:—To use a lever, fulcrum, on incline-plane principle to lift the weight of the gun, and to create a pivoting motion on an optional point; to take the shock always at a right angle to the force of the recoil, the strongest part of the gun meeting the strongest part of the carriage; as much as possible to avoid cog-wheel motion; to make the muzzle-pivoting gear wholly independent of the application of power, so that the derangement of one might not interfere with the action of the other; so to construct the carriage that for constant discharges at high angles it could serve in a mortar bed, which is effected by scotching up the trunnions in the slot of the carriage readily and efficiently with a lot of hand-spikes, timber, or simply adjusted quoins, and, if possible, to make the carriage serve both purposes of muzzle and trunnion pivoting—the latter in case of derangement to the muzzle-pivoting gear. In March, 1866, he had forwarded his invention to the War Office, but it was then, as now, in a general sort of way rejected and disapproved as inapplicable to the service. The details of the carriage were then given at length, after which the author made pointed statements of the injustice of the official treatment he had experienced. A Heathorn carriage was ordered by the Admiralty for experiments in the spring of last year, but was, however, never constructed, for, later, he was informed that a somewhat similar plan was in course of construction in the Arsenal for experimental purposes, and that no further steps concerning his carriage could be taken until the results of this trial were made known. He considered his carriage had suffered by the fact that he had first been instructed to omit all details of accessories, and that afterwards this omission was made an objection to its trial. In the discussion, Captain Mitchell, Sir H. Codrington, and Mr. Mallet took part. The chairman, Sir John Boileau, quite agreed that muzzle-pivoting must become the recognized system. At present, either in guns or forts, nothing can be said to be settled, though we may have the germs of the future weapons and defences. For naval purposes the muzzle-pivoting system is excellent, a small aperture being the great feature, and outbalancing any disadvantages. The officers who bring forward new systems deserve the best thanks of the institution.

The Rosedale and Ferryhill Iron Company, we, the "Newcastle Daily Journal," are glad to learn, have struck the Harvey seam, upwards of 4ft. thick, at their Jane Pit winning, at Ferryhill. As the sinking is close to the blast furnaces, this fine bed of coal will be an immense gain to the company, who contemplate raising upwards of 2,000 tons of coal per day, and erecting several hundred coke ovens to convert the small coal into coke, which can be delivered to the furnaces without the usual heavy railway carriage that swells so largely the working expenses of the manufacturer, and not unfrequently operates as a barrier to the development of large and costly undertakings.

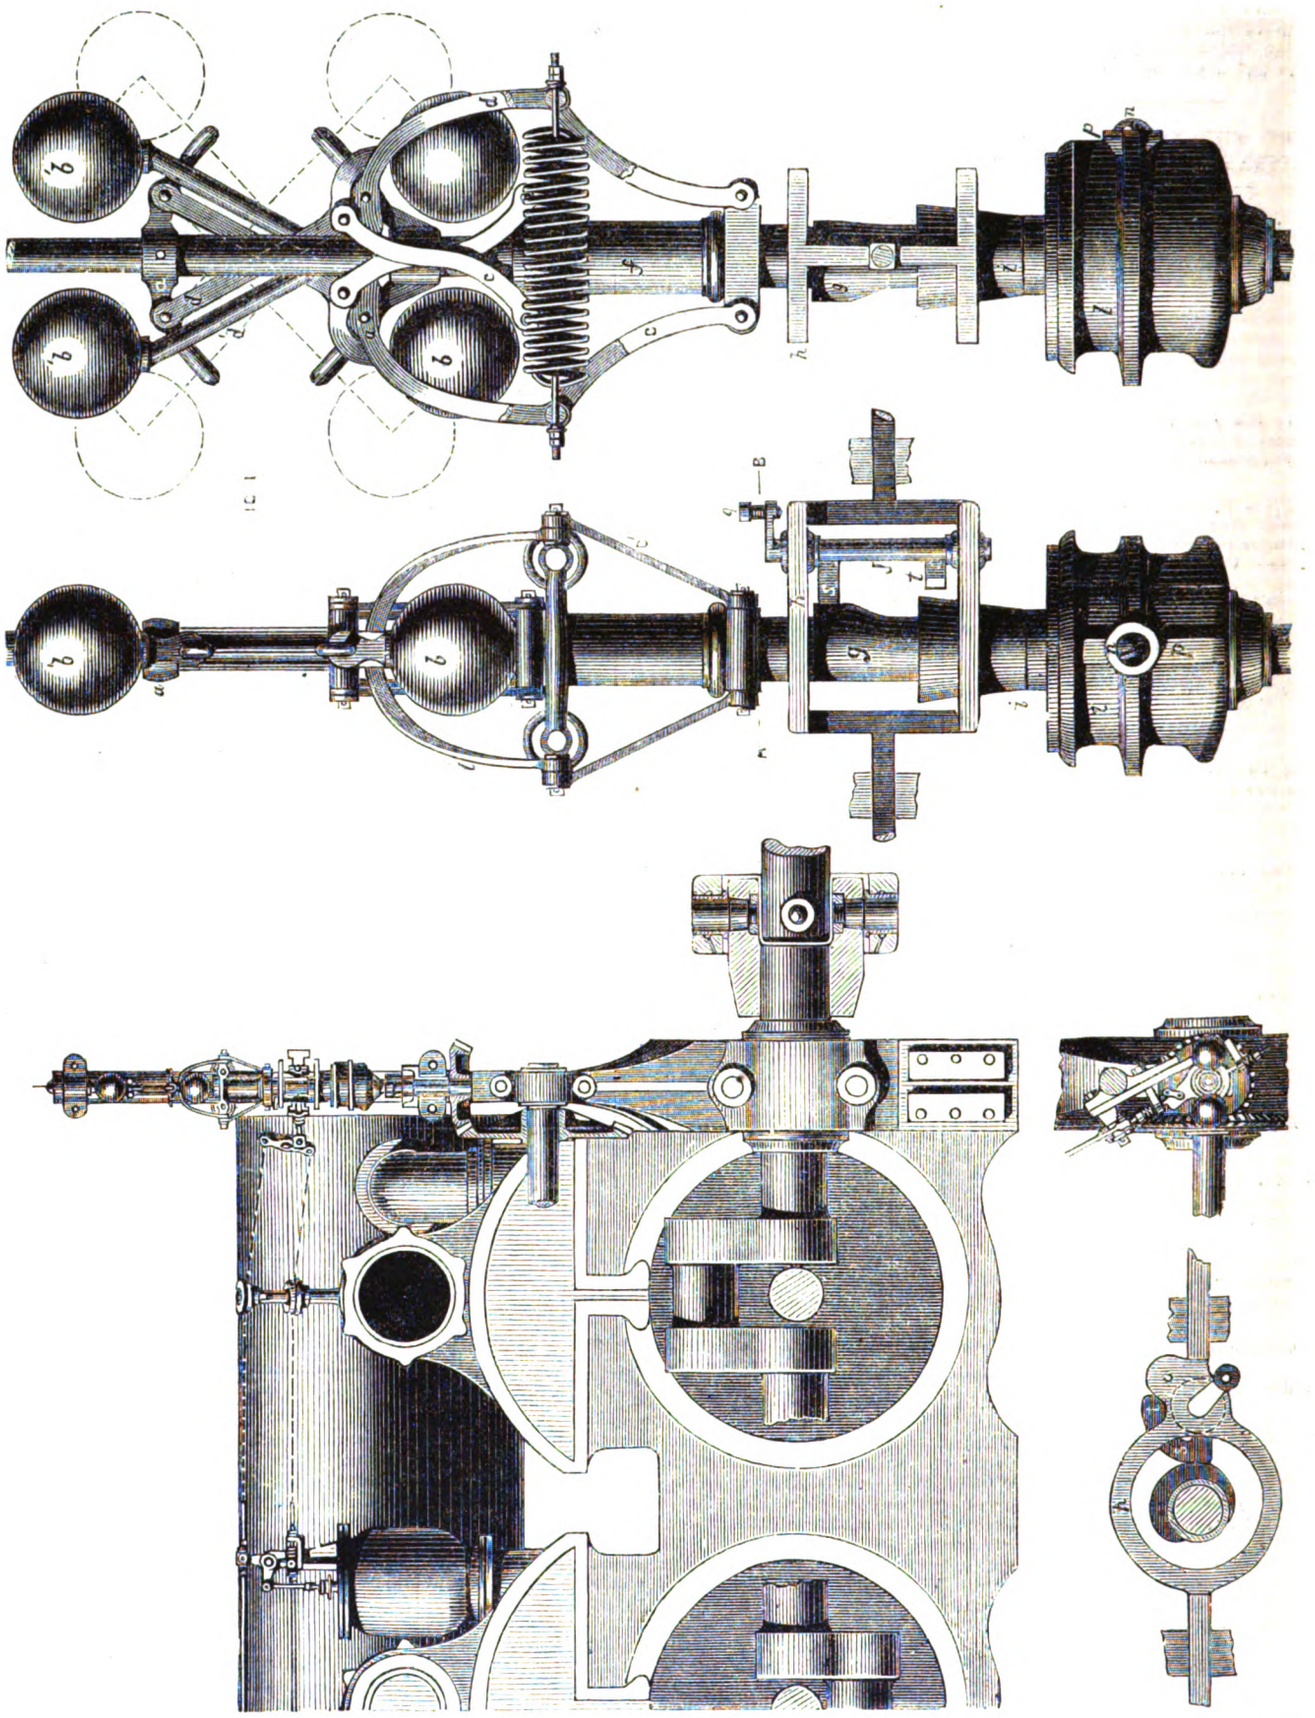
FOUR BALL MARINE GOVERNOR.

BY MESSRS. FARCOT AND SONS.



FOUR BALL MARINE GOVERNOR.

THE governor, which we illustrate in the accompanying engraving, and which was designed by Messrs. Farcot and Sons, engineers, of St. Ouen, is fitted on board the French Government steamer "Hamelin." It consists of four balls, *b* *b*^{1}, &c., which are connected by means of the arms *d* *d*, *c* *c*, with the sliding collar *f*. The upper balls are made somewhat heavier than the lower pair, in order that the extra weight may act as a counterpoise to the weight of the attachments. The centrifugal force is counteracted by a spiral spring fitted with accurate adjustments. The collar is fitted with two cams *g* and *i*. The shape of the cam *g* is shown in the sectional plan, and the point of the cut-off of the steam depends upon the action of this cam upon the tappet *s*, from which the motion is transmitted to the valve gear through the frame *h*, and the flexible cord shown by dotted lines in the front elevation of the cylinders. The throttle valve is worked by the cam *i*, which acts on the tappet *t*, also attached to the spindle *j*. The amount of opening of the throttle valve depends upon the

Digitized by Google

diameter of that portion of the cam c which acts against the tappet. An air cylinder l is adapted to the base of the governor, in which works a piston is attached to the sliding collar f. This piston is for the purpose of preventing the too rapid revolution of the balls, and the set screw n, inserted in the passage p, serves to regulate the discharge of the air from one side of the piston to the other, and by this means the space, and consequent position, of the ball is regulated.

ON THE THEORETICAL LIMIT OF THE EFFICIENCY OF PROPELLERS.*

By W. J. MACQUORN RANKINE, C.E., LL.D.

1. THE following statement of a certain theoretical limit towards which the efficiency of propellers may be made to approximate by mechanical improvements, and of certain causes which make the actual efficiency fall short of that limit, although it involves no new principle, may be useful in the present state of the question of propulsion.

To avoid complexity, let the water be still when the action of the propelling apparatus begins; so that its velocity relatively to the vessel (which may be called the velocity of feed of the propelling apparatus), is simply equal and opposite to the speed of the vessel. Let that velocity be denoted by v.

2. Let s be the true slip, or acceleration, or additional velocity, impressed on the water by the propelling apparatus; so that $v + s$ is what may be called the velocity of discharge from the propelling apparatus, relatively to the vessel.

3. If W is the weight of the mass of water acted upon in each second, and g the acceleration produced by gravity in one second, the reaction of the water, equal and opposite to the resistance of the ship, is well known to be given by the following formula,

$$R = \frac{W s}{g}; \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and the effective power, or useful work per second, done in driving the ship, by the formula,

$$R v = \frac{W v s}{g} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

4. When the apparatus first takes up a supply of water, then carries it for a time along with the vessel, and then discharges it, the reaction R may be the resultant of a forward reaction $-\frac{W}{g}(v + s)$ exerted by the water when discharged, and a backward reaction $-\frac{W v}{g}$, exerted by the water when received; but in this, as in other cases, the resultant reaction is $\frac{W s}{g}$.

5. In order that the loss of work may be the least possible, the propelling instrument should be so contrived as to act on each particle of water with a velocity at first simply equal to the velocity of feed v, and gradually increasing at an uniform rate up to the velocity of discharge $v + s$. If this condition were fulfilled, the mean velocity with which the propelling apparatus would have to work against the reaction R would be $v + \frac{s}{2}$; and the total work per second would be

$$R\left(v + \frac{s}{2}\right) = \frac{W v s}{g} + \frac{W s^2}{2g}; \quad . \quad . \quad . \quad . \quad (3)$$

in which equation, the first term is the useful work per second, as already given in equation 2, and the second term is the lost work, reduced to a minimum: for it is easy to see that this lost work is simply the actual energy of the discharged water, moving astern with the velocity s relatively to still water; and that quantity of energy must necessarily be lost under all circumstances.

6. The corresponding value of the efficiency, or ratio of the useful to the total work, is

$$\frac{v}{v + \frac{s}{2}}; \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and this is the theoretical limit to the efficiency of a propeller.

7. It is certain that no actual propelling instrument has ever attained the limit of efficiency stated above. It is probable that the nearest approach to the theoretical limit of efficiency is made by the oar; for the skilful rower pulls with a nearly uniform force, and thus produces a gradual acceleration of the water laid hold of by the blade.

In the following articles are described some causes of additional loss of work, irrespective of friction. Those causes may be briefly enumerated thus:—Suddenness of change from the velocity of feed to the velocity of discharge; transverse motions impressed on the water; and waste of the energy of the feed water; and the effect of each of them is to waste work in the production of eddies.

8. Suddenness of the change from the velocity of feed to the velocity of discharge operates to the full extent in every case in which the propeller, instead of beginning its action with the velocity of feed v, and gradually increasing its speed to the velocity of discharge $v + s$, acts throughout with the velocity of discharge $v + s$. Thus the total work per second becomes

$$R(v + s) = \frac{W v s}{g} + \frac{W s^2}{g}; \quad . \quad . \quad . \quad . \quad . \quad (5)$$

so that the lost work, instead of being simply equal to the actual energy of the water discharged per second, is increased to double that quantity of energy; and thus besides the unadvoidable loss of work, there is a waste, or unnecessary loss of work $\frac{W s^2}{2g}$ per second, expressed by $\frac{W s^2}{2g}$.

The corresponding value of the efficiency is

$$\frac{v}{v + s} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

The object of such inventions as Woodcroft's gaining pitch screw, and Mangin's screw, is to diminish waste of the kind that has now been described; and in Ruthven's form of centrifugal pump the same principle appears to be kept in view. The same is also the object of making paddles feather so as to enter the water edgewise. It is probable that the object is partly attained by all those inventions, but by none of them wholly; and such being the case, the loss of work may be expressed by $\frac{c W s^2}{2g}$; c being a multiplier, not exceeding unity, depending on the mode of action of the particular propeller employed. It is probable that in a well-designed centrifugal pump, c may be very small; while for ordinary paddles and screws it is $= 1$.

9. Transverse motions are impressed on the discharged water by all forms of the screw and paddle.

Let u denote the transverse component (whether vertical, horizontal, or inclined) of the velocity of the discharged water. Then if that motion is impressed gradually, the work wasted per second in producing it is $\frac{W u^2}{2g}$, and if more or less suddenly $(1 + c^1)\frac{W u^2}{g}$; c^1 being a multiplier n t exceeding unity; and the latter is the more common case. The jet propeller is free from this cause of waste of work.

10. Waste of the energy of the feed water may occur in those cases in which the water acted upon by the propelling apparatus is received into the vessel and carried along with her before being discharged; that is to say, in certain forms of jet propeller. The feed water has, relatively to the ship, the velocity v; and in order that the energy due to that relative velocity may not be wasted, it is necessary either that each particle of water should begin to be acted upon by the propelling apparatus without losing any part of that relative velocity (as in the case of the screw and the paddle) or that any loss of velocity should be compensated by a corresponding increase of pressure, to cooperate with the propelling apparatus in producing the velocity of discharge $v + s$. For example, if the feed water is taken into a space in which it is sensibly at rest relatively to the ship, it should produce by its impulse on the water previously in that space the whole head of pressure due to its relative velocity $\frac{v^2}{2g}$, otherwise energy will be wasted, in producing eddies in the confined water, to an amount per second which may be expressed by $\frac{f W v^2}{2g}$; f being a multiplier whose value may range from an insensibly small fraction to unity, according to the degree of suddenness with which the velocity of feed is checked.

11. The multiplier f may even take values greater than unity, if the feed water is "throttled:" that is, if it is drawn through openings so narrow that the velocity becomes for a time greater than v, and then falls suddenly by the water entering a large receiver.

12. The following is a summary of the results arrived at in the preceding articles:—

		Ratio to the useful work.
A. Useful work per second	$R v = \frac{W v s}{g}$	1
B. Work unavoidably lost, being the energy of the discharged water	$\frac{R s}{2} = \frac{W s^2}{2g}$	$\frac{s}{2v}$
C. Additional work wasted, through suddenness of action of the propeller on the water	$\frac{c R s}{2} = \frac{c W s^2}{2g}$	$\frac{cs}{2v}$
D. Work wasted through transverse motion of the water if produced gradually	$\frac{W u^2}{2g}$	$\frac{u^2}{2vs}$
E. Additional work wasted if transverse motion is produced suddenly	$\frac{c^1 W u^2}{2g}$	$\frac{c^1 u}{2vs}$
F. Work wasted, through loss of energy of feed water	$\frac{f W v^2}{2g}$	$\frac{fv}{2}$

13. The following particular case may be specially mentioned. Suppose that the velocity of discharge is impressed gradually (so that $c = 0$), that there is no transverse motion of the discharged water (so that $u = 0$), and that all the energy due to the velocity of feed is lost (so that $f = 1$). Then the total work per second is—

$$R v\left(1 + \frac{s}{2v} + \frac{v}{2s}\right) = \frac{W(v+s)^2}{2g} \quad . \quad . \quad . \quad (7)$$

being the actual energy corresponding to the velocity of discharge; and the corresponding efficiency is—

$$\frac{2vs}{(v+s)^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

In this case the lost work becomes a minimum, and the efficiency a maximum when $s = v$; and such is very nearly the case in the "Nautilus" and the "Waterwitch."

14. In the following example the data assumed are—

$W = 5$ tons, or 11,200lb. per second;

$v = 15$ft. per second; $s = 15$ft. per second;

so that $v + s = 30$ft. per second; and R = 5,217lb.; the velocity is supposed to be impressed gradually; and $u = 0$. Then—

	Ratio to useful work.	Foot-pounds per second.	H.P.
A. Useful work	1	78,255	142
B. Necessary loss of work	½	39,127½	71
F. Additional loss if energy of feed water is wholly wasted	½	39,127½	71
Total work, including the above losses, but exclusive of friction (the efficiency being 0·5)	2	156,510	284
C. Additional loss if the velocity s is impressed suddenly	½	39,127½	71
Total work with that addition, but still exclusive of friction (the efficiency being 0·4)	2½	195,637½	355

15. As another example, let—

$W = 10$ tons, or 22,400lb. per second;

$v = 15$ft. per second; $s = 7\frac{1}{2}$ft. per second;

(so that $v + s = 22\frac{1}{2}$ft. per second, and R = 5,217lb., as before); let $u = 0$; and let the velocity s be impressed suddenly. Then—

	Ratio to useful work.	Foot-pounds per second.	H.P.
A. Useful work	1	78,255	142
B. Necessary loss of work	¼	19,563¾	35¾
C. Additional loss through suddenness of action	¼	19,563¾	35¾
Total work, exclusive of friction (the efficiency being 0·67)	1½	117,382½	213¾

W. J. M. R.

Glasgow University, December 26, 1866.

* From the "Engineer."

The following is a return of the quantity of coal exported from the port of Grimsby, March, 1868:—To Belgium, 1,092 tons; Canada, 974 tons; Denmark, 354 tons; Egypt, 1,206 tons; France, 5,082 tons; Hanse Towns, 805 tons; Holland, 425 tons; Italy, 648 tons; Norway, 377 tons; Spain, 1,267 tons; Sweden, 749 tons; Sardinia, 793 tons; Wallachia and Moldavia, 173 tons—foreign, 15,945 tons; coastw is, 3,452 tons—total, 17,397 tons Corresponding period, 1867:—Foreign, 14,621 tons; coastwise, 3,091 tons—total, 17,112 tons. Increase this year, 285 tons.

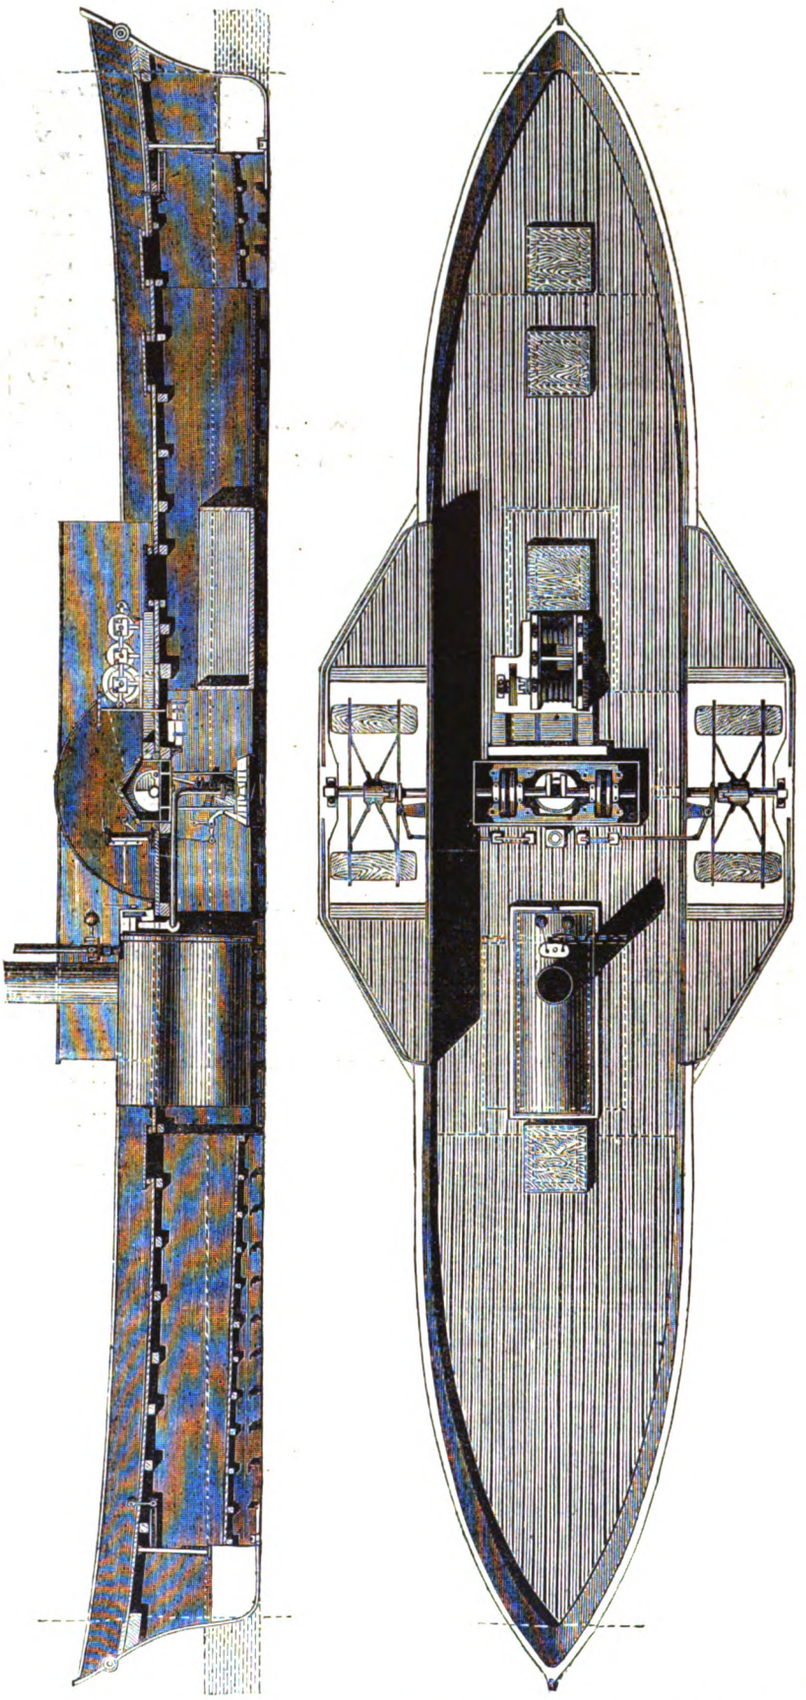
CHAIN TUG BOAT ON THE PAJANE GULF, FINLAND.

BY MESSRS. WILLIAM CRIGHTON AND CO.



CHAIN TUG BOAT.

THE accompanying engravings show a longitudinal sectional elevation and a plan of a chain tug boat built by Messrs. William Crighton and Co., of Abo, Finland. The steamer was built for warping rafts of timber from the upper end of an inland sea called Pajane, to the saw mills at the lower end, which are situated near the coast. The upper end of this sea is in communication with the rivers, which, in spring, float the timber from parts still further north to the Pajane. The distance is about seventy English miles, and this steamer, with about 1,000 fathoms of ¾in. chain, warps a raft of timber consisting of between 6,000 and 7,000 trees this distance in from five to six days, depending upon the weather. There is little or no current, but the sea being in some places twelve to fifteen miles broad, the steamer has often to contend with contrary winds. Before she came into use, the transporting of the raft from the one end of the sea to the other often occupied a whole season with horses. A steamer of 80-horse power, some years ago, tried to tow the raft without being able to make the least impression on it.

It is here necessary to explain that the raft is not made in the ordinary way, but why is not so easy to explain; in the meantime, we may state that the sawmill owners, after repeated attempts to get the peasants to form their rafts like other people, were obliged to give it up. The proper name, instead of raft, would be to call it a floating field of timber, and its formation is thus attained:—An enclosure is formed around the mouth of the river, down which the trees are, in the first instance, floated; this enclosure consists of floating trees with their ends lashed together, so wide as to contain 6,000 or 7,000 trees. The ends of the enclosure are secured to the land, and are released so soon as it is full. The ends are then brought together until the whole forms an immense loop, and, in this state, without reference as to how the trees are lying, they are warped or towed to their destination by the steamer.

The stems of the boat are forged with an opening just above the deck, for receiving an ordinary block sheave, the chain is led through this opening, and has an anchor at its end with large flukes and large timber stock, which description of anchor is found to hold best in the generally very soft bottom of the Pajane. The steamer has 1,000 fathoms of chain on board, she anchors at about that distance from the raft, practice enabling the men to take the distance by the eye. The windlass upon deck having six turns of chain on the barrels, is then disconnected from the engines, and the engines connected to the paddles, and the boat being supplied with a rudder at both ends, goes back towards the raft, and having become attached to it, disconnects her engines from the paddles, and the engines being thrown into gear with the windlass, the warping commences, and goes on thus until the raft reaches its destination, and so quickly is each operation or warping executed through a little practice, that it is not found necessary to anchor the raft whilst the steamer is taking a fresh hold.

The windlass is furnished with a brake, so that the paying out of the chain can be regulated by the speed of the boat. All the disengaging handles, starting and steering gear, are close to one another on deck. The engines are oscillating, fitted with the link motion, and the boat being quite alike at both ends, goes either way. Instead of ordinary cranks, the shafts have cast-iron discs fitted to them, which act as fly-wheels when the engines are disconnected from the paddles, and the windlass is driven from one of these discs by means of a pitch chain. The boat is built of Swedish iron, 90ft. long, 15ft. 6in. beam, 5ft. 6in. depth of hold; draught, 3ft., with 1,000 fathoms of chain on board. Fitted with a pair of condensing engines with 20in. cylinders, and 21in. stroke. It has been tried to attach the chain to the raft, and advance with the steamer as far as the length of the chain would permit, but this is not found to answer as well. The whole cost of this boat, with about 1,000 fathoms of ¾in. chain, as she now stands on the Pajane, was £2,600.

LIGHTING THE EUSTON-SQUARE STATION.

THE principal hall at the Euston-square station is now lighted on a new principle, which appears to be working very successfully. It may be remembered that under the old system the hall was lighted by ordinary burners, consuming 280ft. of gas per hour. The light was dismal in the extreme, and the beauty of the building was quite obscure. Under the new system (Kidd's patent), which has been applied by Messrs. Sim, Barff and Co., of 92, Cannon-street, the hall is lighted by the use of two bell-shaped vessels, containing dead oil. The consumption of gas is reported to be 100ft. per hour, and a very small quantity of oil is evaporated. The result is a light by which the smallest print can be easily read in any part of the hall. The booking office is also lighted on this principle.

THE foundation stone of the bridge to cross the Mississippi River at St. Louis, was laid on the 25th ult., in presence of a large number of citizens.

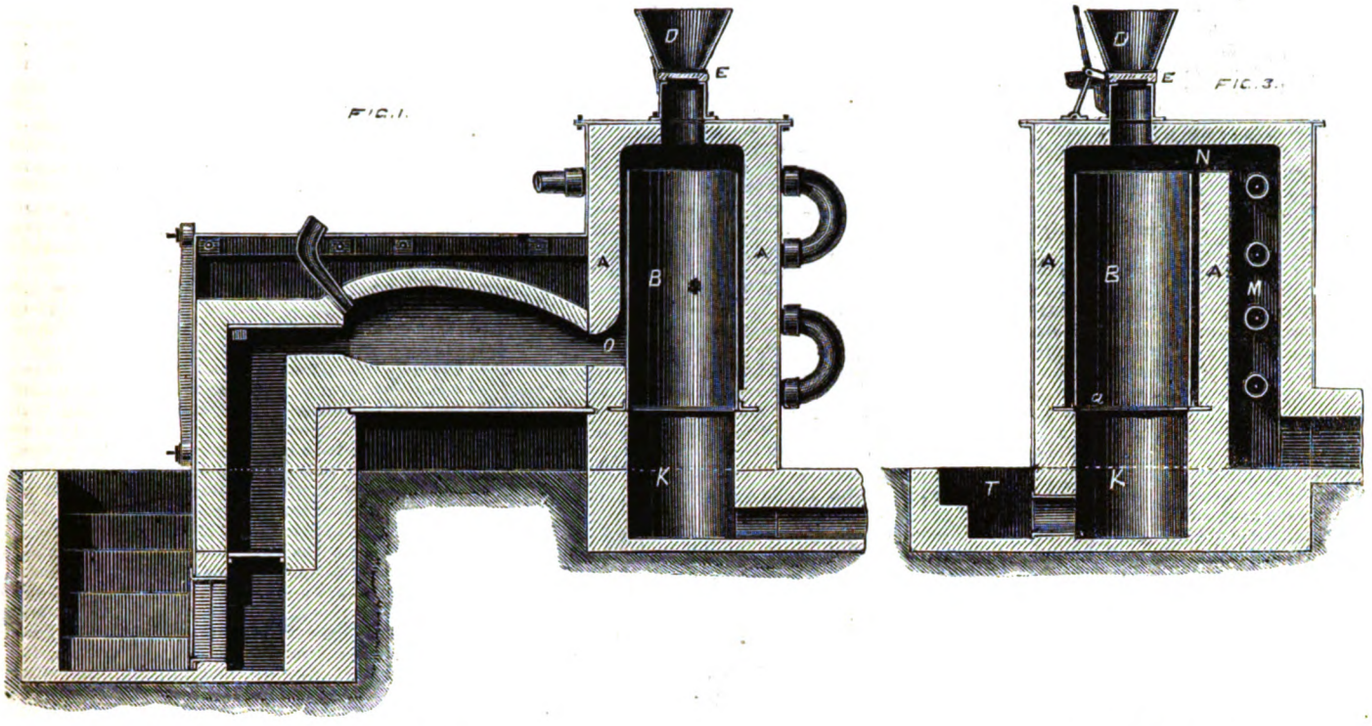
APPARATUS FOR PRODUCING COMBUSTIBLE GASES.

BY M. LEBEDEFF.

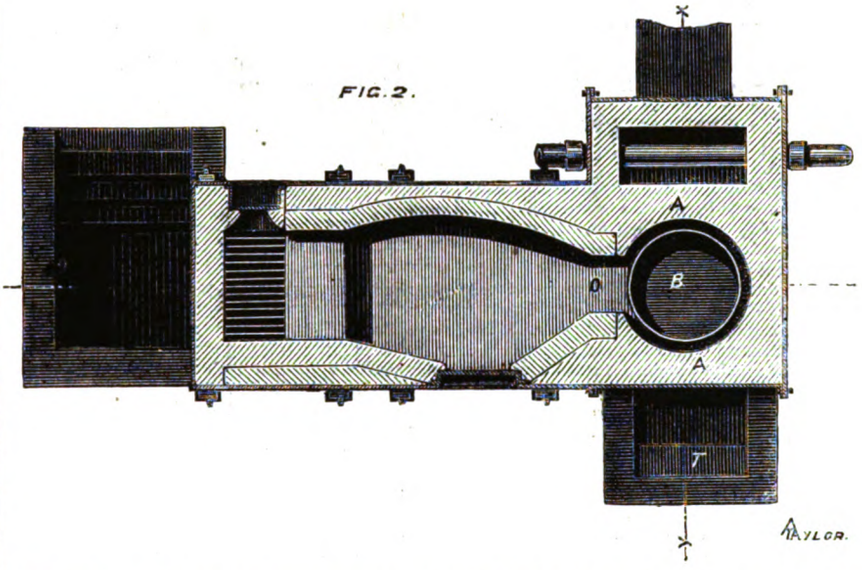


CONVERTING GASEOUS PRODUCTS INTO COMBUSTIBLE GASES.

THE invention illustrated in the above engraving has for its object the utilization in a very advantageous manner the waste heat of furnaces and fireplaces. It is the patented invention of M. Nicolas Lebedeff, a mining engineer, of St. Petersburg. It consists mainly in employing the waste heat to effect the regeneration of the gaseous products of combustion from the furnace or fireplace, that is, to convert the gases, which consist mainly of carbonic acid and vapour of water, into combustible gases, such as carbonic oxide and hydrogen. For this purpose the products of combustion are made to pass from the furnace partly through a cylinder of refractory material filled with carbonaceous matter, and partly through a space surrounding the cylinder, so as to heat the carbonaceous matter it contains. By this means that portion of the gases which passes through the cylinder is converted into combustible gas, which may be used for heating purposes either in the same furnace or elsewhere. The other portion of the gases, after imparting a portion of their heat to the contents of the cylinder, is conducted into a chamber where they are employed to heat the air required for the furnace.

Fig. 1 in the accompanying engraving shows a longitudinal section through a furnace and regenerator constructed according to M. Lebedeff's invention. Fig. 2 shows a sectional plan of the same, and fig. 3 shows a sectional elevation of the regenerator on line X X, fig. 2. The gases issuing from the furnace enter the regenerator A through the opening O, and in passing through the annular space surrounding the cylinder B they impart to the latter the requisite amount of heat for the regeneration of the gases passing through it. Arrived at the top of the cylinder the gases divide into two portions, of which one passes through the space N into the apparatus M for heating the air required for combustion in the furnace. The other portion passes down through the cylinder B, and in doing so is converted into combustible gases, which on issuing from the bottom of the cylinder are conducted through the passage K where required. The cylinder B is charged with carbonaceous matter through the hopper D provided with a sliding bottom E. The cylinder at the lower end is provided with a grating, and the attendant has access to the space below by means of the steps T for the purpose of removing the ashes of the burnt carbonaceous matter.

In constructing this apparatus the following points have to be attended to, firstly, the regenerator must be kept as close as possible to the furnace, of which the waste heat is to be utilized; secondly, the chimneys for producing the requisite draft must be provided with regulating dampers; thirdly, the gas passages must be impermeable to the external air, as otherwise explosions might take place. According to M. Lebedeff, this apparatus offers the following advantages:—Firstly, an economy in fuel to the extent



of fifty per cent., as for each equivalent of carbonic oxide only one-half of the carbon comes from the fuel, the other half being derived from the gases issuing from the furnace. Secondly, an increase of temperature on account of the decomposition of the aqueous particles contained in the fuel. Thirdly, all kinds of fuel of inferior quality may be employed. Fourthly, the apparatus is of very simple construction, thus permitting of its being applied at a very low cost to all kinds of furnaces, ovens, or kilns. In addition to the above the waste heat of a furnace may by this means be utilized at any distance away from it, and there is no necessity for this purpose to put, for instance, a boiler over the furnace.

THE SOCIETY OF ARTS' ALBERT MEDAL.

THE time draws near when the council of the Society of Arts will award the Albert Medal of the Society, and doubtless there are not a few expectant recipients. It is just possible, however, that the medal will be bestowed where least expected. But in order that every one who can show any title to it may have his claims fairly considered, the council invite members of the Society to forward to the secretary, at the Society's house, the names of such men of high distinction as they may think worthy of this honour. And its award is an honour, for it was instituted to reward distinguished merit in promoting arts, manufactures, or commerce. In the year 1864, this medal was awarded to Sir Rowland Hill, for his great services to arts, manufactures, and commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which have, however, not been confined to this country, but have extended over the civilized world. In 1865 it was awarded to the Emperor of the French, for distinguished merit in promoting, in many ways, by his personal exertions, the international progress of arts, manufactures, and commerce, the proofs of which are afforded by his judicious patronage of art, his enlightened commercial policy, and especially by the abolition of transports in favour of British subjects. The following year saw it inscribed with the name of one of England's greatest philosophers—Professor Faraday, to whom it was awarded for discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted arts, manufactures, and commerce. Last year it was given in duplicate to Mr. W. Fothergill Cooke and Professor Wheatstone, in recognition of their joint labours in establishing the first electric telegraph. Whose shall be the next name on the roll of honour?

ON THE PORT-GLASGOW WATER-WORKS.*

By MR. JAMES M. GALE, C.E.

IN the autumn of 1864, when these works were designed, Port-Glasgow contained a population of about 9,000, but from the increasing commerce of the River Clyde, and the development of ship-building and engineering works of all kinds in the towns on its banks, it was thought proper to provide an immediate supply of water for 12,000 people, and to establish the works in a district capable of furnishing a supply for 20,000 inhabitants. The daily supply per head it was considered expedient to provide for was 30 gallons, making a total daily supply for present purposes of 360,000 gallons a day; while the whole works were arranged so that the supply could be ultimately increased to 600,000 gallons a day.

Geologically the country to the south of Port-Glasgow is trap, which rises into a ridge, at one point 995ft. high, extending from Greenock to near Bishopton, a distance of about nine miles. This ridge separates the valley of the Gryfe from that of the Clyde, and is distant from one to two miles from the south bank of the Clyde. The streams flowing from the northern slopes of the ridge are short and rapid, and no site for a good storage reservoir existed on them, except one which had been appropriated by one of the large manufactories of Port-Glasgow, and which drained a considerable area of deep peat, and discharged water stained to an objectionable extent. A depression in the ridge about one and a-half mile south from the banks of the Clyde and three miles south-east of Port-Glasgow presented the only other position where a reservoir of sufficient size could be constructed, unless the Gryfe itself had been selected, while it possessed the additional recommendation that the ground draining into it was entirely without peat; and as the whole area consists of trap, the water flowing from it is extremely soft and brilliant, and admirably suited for all domestic purposes. The quantity of water which can be collected in this locality is more than sufficient to supply even a greater population than the 20,000 it was thought proper to look forward to, and it was accordingly selected as the source of supply.

The reservoir which has been constructed, being in a depression in the ridge above referred to, intercepts the drainage from an area of 162½ acres, which formerly flowed to the Gryfe, and a very short diversion cut brings the water into the reservoir from 62½ acres, which formerly flowed into the Finlayston Burn, a stream which discharges into the Clyde at Finlayston House—making the total drainage area to the reservoir 225 acres. No rain gauges have been kept in the district nearer than those in connection with the Shaws Water-works, but as these works are only about seven miles to the west, the results obtained there have been taken as affording sufficiently reliable data; and the amount of rainfall which can be collected has been assumed at 36in. for a dry year. An available fall of only 30in. over the area draining into the reservoir would give considerably more water than is wanted for 12,000 people, while another reservoir constructed on the Finlayston Burn at a point somewhat lower down the stream would intercept the drainage from about 250 acres of additional land, and together with the works which have been constructed, would be capable of supplying more than 20,000 people.

The delays and discussions which so frequently accompany or precede the construction of water-works were not experienced in the case of Port-Glasgow. The writer of this paper received orders from the Town Council to examine the country and report on the best source available for the town in September, 1864. The recommendations in the report were immediately adopted, and Parliamentary plans for the works were lodged in the same year, and the Act received the Royal Assent in July, 1865. The works were commenced in April, 1866, and were completed and formally opened on October 15, 1867. Throughout the whole time the greatest unanimity prevailed among the community of Port-Glasgow; and the land-owners whose land and streams were affected by the works not only did not oppose, but gave all the assistance in their power in carrying out the work.

The reservoir is partly formed upon the site of what must at one time have been a small natural lake, which had got nearly filled up by the washings from the adjoining slopes, and had formed a flat marshy basin, the low ground being of little value, but the whole site forming an admirable place for a reservoir. Two embankments were required—one at the south of Gryfe end of the reservoir, and another at the north of Finlayston Burn end, and the depth of water impounded above the level of the marsh is 15ft. The embankment at the south end is the most extensive. It is 275yds. long, and 35ft. high from the bottom of the puddle trench to the top of the embankment. The north embankment is only 77yds. long, and 16ft. high. Both embankments have inside slopes of three to one, and outside slopes of two to one; are 12ft. broad at top, are carried about 4ft. above top water level, and have puddle walls 8ft. thick at top, with a batter of one inch to the foot on each side. The byewash is 10ft. wide, is placed at the east end of the south embankment, and discharges into the stream flowing to the Gryfe. A cast-iron pipe, 10in. diameter, is placed through this embankment for discharging the compensation water to be given out of the Gryfe, and a weir is constructed behind the embankment for gauging the flow.

The reservoir contains 9,000,000 cubic feet, or 56,500,000 gallons, has a water surface of about 21¾ acres, and when full is 319·67ft. above the mean level of the sea. The compensation water to the Finlayston Burn has been fixed at four gallons a minute, but that for the stream flowing to the Gryfe has not yet been determined. After making ample allowances the reservoir contains 130 days' supply for 12,000 people at 30 gallons a head a day.

The water for the supply of the town is drawn from the reservoir by a 10in. cast-iron pipe through the north embankment, which communicates with a cast-iron stand-pipe inside the reservoir, 3ft. 6in. inside diameter, furnished with valves, by means of which the water can be drawn from the reservoir at three different levels. The valves are worked from the top of the stand-pipes, which communicates with the embankment by a wrought-iron foot bridge, and the openings into the stand-pipes are so arranged that the valves can be taken out and repaired or renewed, without interrupting the supply to the town.

The water is gauged as it flows from the reservoir over a weir at the outside tail of the embankment, and is conveyed by a fire-clay pipe conduit, 9in. diameter, for a distance of 495yds., and for a further distance of 2,005yds., by a 15in. fire-clay pipe conduit to the filters at Parkhill. The 9in. part of the conduit has a considerable fall, and is capable of conveying the 360,000 gallons a day, for which the works have been constructed. The 15in. part has a fall of 1 in 350, and is large enough to convey 600,000 gallons a day. It commences near the point where the next reservoir will be constructed when Port-Glasgow comes to require more water than the present works will give. The pipes forming the conduit were jointed with cement and concrete, with great care, so as to exclude all surface water.

The works at Parkhill consist of a gauge-well for gauging the flow of water as it is received from the conduit; a filter; a clear water-tank; a valve-well, with valves for regulating the flow from the tank; and a box for washing the filtering sand. The filter has an area of 270 square yards, and a depth of 4ft. of filtering materials, which are disposed in the following order:—

	Feet.	Inches.
Broken whinstone metal, 3in. ring	1	0
Do. 2in. ring	0	7
Gravel	0	3½
Perforated glazed fire-clay tiles 10in. square, 64 holes in each tile	0	1½
Sand from Brodick	2	0
	4	0

The tank is circular, 55ft. diameter; 13½ft. deep, 13ft. of which can be drawn off by the town main, contains 193,000 gallons, and when full is 271ft. above Ordnance datum. The walls are of ashlar, 18in. thick at the bottom, and 15in. at the top, and the whole is puddled so as to be perfectly water-tight. A frame, carrying copper-wirecloth strainers, is fixed to the inside end of the supply-pipe, to exclude all minute particles which may accidentally find their way into the clear water basin. The valve-well is circular, 7ft. inside diameter, with cast-iron pipes communicating with both the gauge-well and the filter, arranged in such a manner that water can be uninterruptedly supplied to the town, while either the filter or clear-water tank is under repair or being cleaned out. The apparatus for washing the filtering sand is similar to that first erected by the writer at the Gorbals Waterworks in 1854, and successfully worked ever since with little or no repair. It consists, in this case, of a wooden box, of capacity sufficient to contain 1½ cubic yard of sand, with a false bottom of perforated cast-iron plates, upon which the sand rests. Water, under a head of a few feet, is introduced between the true bottom of the box and the perforated plates, which causes an action in the sand resembling boiling. The attrition of the particles of the sand rubs the whole perfectly clean in about 15 minutes, with the assistance of very little manual labour, and with not a great expenditure of water. The cost of this operation, with similar apparatus, at the Gorbals works, amounts to 6d. per cubic yard of sand. All these works at Parkhill, with the exception of the filter, are designed for a supply of 360,000 gallons a day only, and ground has been purchased on which to erect an additional filter.

The main-pipe, from the clear-water basin to the town, is 9in. diameter, and 2¼ miles long, to the Court-houses, near the harbour. It is carried principally along the old road from Port-Glasgow to Glasgow, which is at a considerably higher level than the new road, the line of which should be taken for a second main when it is required. All the cast-iron pipes have turned and bored joints, and were driven home with a little fine cement to make the joint. Air-cocks are placed on all the summits on the line of main, and scour-cocks in all the hollows. The distributing-pipes ramify the streets of the town in the usual way. They are not interlaced in any way, but are each furnished with a valve where they leave the main, and a cleansing-cock at the further end. The fire-cocks, of which there have been 150 placed throughout the town, are of the kind known as Bateman and Moore's ball valves, and have cost about 27s. each complete. They are found to work well, and to require little repair, and they have the additional recommendation that they act as air-cocks. The full pressure, due to the elevation of the tank, is constantly on the distributing-pipes, and, in the event of fire, there should be a good supply of water.

There was nothing new introduced in the service-pipes and water-fittings, except it be the attachment of the service-pipes to the cast-iron distributing-pipes. Instead of the usual detached cock and ferrule, a cock was used with a ferrule attached at an angle of 45deg., the attachment to the pipe being made at an angle of 45deg. off the perpendicular. These cocks had been previously introduced by the writer in the towns of Dumbarton and Hamilton, where they have been quite successful, and cost less than the ordinary arrangement.

The cost of the whole works has been as follows:—

Reservoir	£1,339
Conduit, filter, and clear-water tank .	2,230
Pipe laying	1,018
Cast-iron pipes and special castings . .	3,620
Valves, fire-cocks, &c.	251
Land and expenses connected therewith	2,347
	£13,805

The contractor for the reservoir, conduit, filter, tank, and pipe-laying was Mr. John Murray, Glasgow; for the cast-iron pipes, Messrs. Robert Maclaren & Co., Glasgow; for the valves and fire-cocks, Messrs. Guest & Chrimes, Rotherham; and for the special castings, Messrs. Alston & Gourlay, Glasgow. The resident engineer was Mr. James Wilson, and the inspector of works, Mr. John Wilson. The whole of these gentlemen executed their work and discharged their duties to the entire satisfaction of the writer.

*Read before the Institution of Engineers in Scotland March 11, 1868.

GAS ENGINEERING.

NO greater proof is required of the incompleteness of knowledge upon any given subject than that afforded by the frequent publication of information thereon. For assuredly if everything were known, then should we require no teachers. In gas engineering we specially have to notice the occasional appearance of books, which, while purporting to serve a business purpose, are really the media of valuable information upon the subject of which they treat. Each one, too, goes beyond its predecessors in imparting practical knowledge, and thus bears testimony to the truth of our observation that generally the knowledge upon given subjects is incomplete. Some of these books give information by description, others by illustration. Of the latter class is one which has just been issued by Messrs Christie and Co., the gas engineers and contractors, of Bankside, Southwark, of which firm Mr. Alfred Williams (well known to our readers as the Honorary Secretary of the Society of Engineers

Digitized by Google

is the active and acting partner. To Mr. Williams, in fact, is due the production of the book before us, which of course does not pretend to be more than an illustrated price list, but in outward appearance it is a respectable-looking volume. On opening it we find it to consist of a series of twenty folding sheets of lithograph drawings, illustrative of every apparatus and implement used in the manufacture of gas. These plates are interspersed with brief descriptive matter, including dimensions and other information of value to managers of gas works. We first have some light iron roofs for the various buildings on a gas works, after which follow retorts, showing their settings and their details, together with all the necessary fittings. We then come to the condensers, of which there are two kinds illustrated—the ordinary and the annular—the latter being a great improvement upon the former.

Next in order is the exhauster, which is shown with the boiler engine and connections, as carried out in practice. Then come in succession the scrubbers, a series of purifiers with their well-arranged connections, station meters, gasholder tanks, and gasholders. The scrubbers employed by Messrs. Christie are specially noteworthy, being a great improvement upon those of ordinary construction. They are filled with drain tiles, which entirely prevents any addition of pressure by the use of the scrubber, and affords easy escapement for the tar. An interesting plate is that showing the various photometrical apparatus, and where we have the systems of Dr. Letheby, Mr. F. J. Evans, and Mr. Wright graphically illustrated. Following these are illustrations of meters, and of the numerous implements and tools used in gas works. We thus have a collection of drawings of machinery and apparatus embodying all the most recent improvements in practice, and which have been suggested by the long experience of Messrs. Christie and Co. as gas engineers. The execution of the drawings has been entrusted to Messrs. Spon, of Charing Cross—who, in fact, have brought out the book—and this is a guarantee that they are well done. We cannot conclude without specially noticing some well-designed gas stoves for cooking and heating; they are fitted with atmospheric burners, and work at a great economy as against coal stoves. The cooking stoves are well arranged, and are a special boon for domestic use in summer, as they are cool, cleanly, and ready for use at a moment's notice. *Apropos* of this stove we would suggest that our gas companies follow the excellent example set by one company of letting out these stoves on hire, charging a small rental upon them. This the Maidstone Gas Company does, and makes a good round sum annually, whilst the public are well pleased with the saving they effect by such an arrangement and the convenience they possess in such a stove. Having examined one of these stoves at Messrs. Christie's wharf we can strongly commend them to the public.

THE ROYAL AGRICULTURAL SOCIETY.

THE meeting of the Royal Agricultural Society, to be held in Leicester in July, promises to be an unusually brilliant affair. Already tradesmen are busy with their decorations, and "town improvements" are being advanced as rapidly as possible. The show-ground will be situate on the racecourse, which comprises 55 acres, of which 45 acres have been placed at the disposal of the Royal Agricultural Society and the Royal Horticultural Society, who will also hold their annual country exhibition at the same time. This large area, of which about 30 acres have been expressly levelled, is being rapidly enclosed with a hoarding by Mr. T. Penny, of Taunton, Somersetshire, who, it will be remembered, gave so much satisfaction in the erection of the fittings of the last show at Bury St. Edmunds. Already many of the offices are nearly completed. The Midland Railway Company have undertaken to construct a siding (of rather steep gradient), at their own expense, from the main line (south of Leicester) to the show-ground, and this, from the progress which has been made, promises soon to be workable. The space allotted for the show will be the largest yet put at the disposal of the Society, and will consist of one unbroken space, disposed of as follows:—Sheds for implements, 7,500ft. run; live stock, 6,020ft. run; seeds and models, 1,000ft. run; fodder sheds, 180ft run; machinery in motion, 1,390ft. run, in addition to horse-boxes and stalls to accommodate 387; offices, exercising grounds, &c. The show, being so centrally situated, is expected to attract a large influx of persons, and already accommodation is eagerly sought after.

NEW METHOD OF REEFING TOPSAILS.

BY CAPTAIN WEBB, R.N.

FIG. 1.

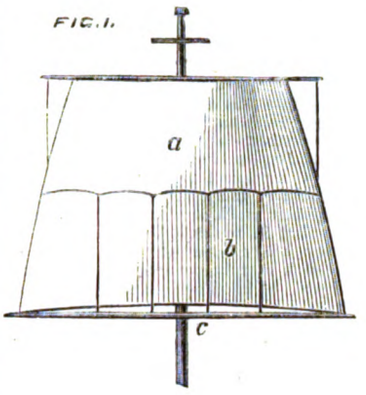

FIG. 3.

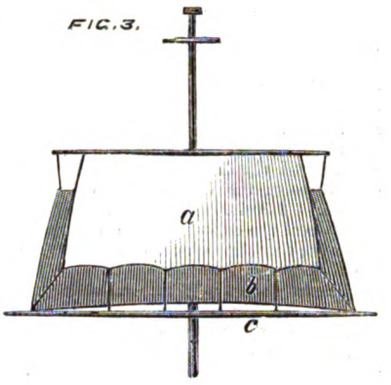

FIG. 2.

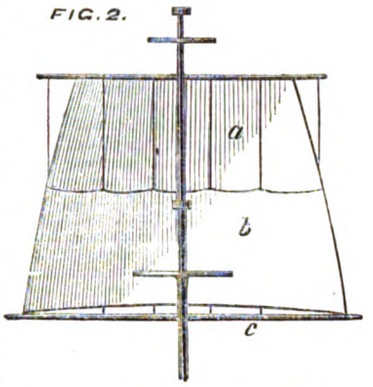

FIG. 4.

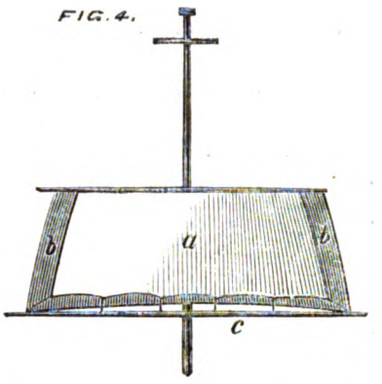

THE BRITISH ARMY.

THE strength of the army at home and abroad in 1866 was 201,641 officers and men. At home there were, on an average, in cavalry, infantry, artillery, and engineers, 4,470 officers and 79,654 men, of whom 3,021 officers and 53,456 men were in England and the Channel Islands. The residue of the home strength, 27,647 officers and men, were in Scotland and Ireland. The large proportion of 24,238 were stationed in the latter country. The proportions of military force in each of the three kingdoms to 10,000 civil population were—England and Channel Islands 26, Scotland 11, and Ireland 43. In the United Kingdom, in 1866, 49 officers, and 1,007 men died. The mortality of officers was 1·096 per cent.; that of the men was 1·264. Abroad there were 6,252 officers and 111,265 men. The number of soldiers was less by about 15,000 than the number abroad in 1864, and less by about 7,000 than the number in 1865. Seventy-nine officers and 1,723 men died abroad in 1866. The mortality was remarkably low, that of officers being 1·264 per cent. against 1·576 in 1865. The mortality of men was 1·549 against 2·102 in 1865. Of the 4,470 officers and the 79,654 non-commissioned officers and men at home in 1866, respectively, 776 and 12,165 were cavalry; 2,766 and 51,179 were infantry; 617 and 13,788 were artillery; and 311 and 2,522 were engineers. Of the 6,252 officers and the 111,265 non-commissioned officers and men abroad in 1866, respectively, 413 and 6,283 were cavalry, 4,192 and 85,882 were infantry, 1,216 and 17,347 were artillery, and 431 and 1,753 were engineers.

REEFING TOPSAILS.

SHIPS frequently have their sails blown away through the inability of the crew to reef with sufficient speed; and, when shorthanded, and sailing under close reefed topsails, advantage is not taken of a short lull of the wind to extend the sails, for fear of another increase of wind endangering the sails. This is all entirely obviated by an invention, recently patented by Captain Webb, R.N., of 4, Woolwich Common, and which has for its object the reefing of topsails from the deck in a speedy, simple, safe, and efficient manner, thereby obviating the necessity of going aloft, and rendering a small crew capable of working a ship in heavy weather. By this invention the topsails can be hoisted and increased in surface, or lowered and reefed with such celerity that no loss of speed need take place when the force of the wind becomes lessened, and the operation of reefing is thereby rendered a far less formidable affair. The alteration can readily be made from common to the patent topsails. The sails can be arranged and bent to the ordinary yards, at a small cost, and without any inconvenience.

The annexed engraving will enable our readers to understand the *modus operandi*, with the aid of the following description. The topsail is divided horizontally into two parts or halves, so that the topsail is composed of an upper and lower topsail. Fig. 1 represents a foreside view of the topsail, as ordinarily set, without reefing, and fig. 2 an afterside view of the same. *a* is the upper topsail, which is attached to the topsail yard in the usual manner. *b* is the lower topsail, the clews of which are attached to the yard *c* with sheets in the usual manner. The head of the lower topsail is fitted with reef tackles and head ropes to draw it taut; the reef tackles being fitted in the usual manner, and the head ropes leading through blocks on either quarter of the topsail yard, and leading from thence to the cleats on deck. The foot of the upper topsail is fitted with sheets and down hauls, the sheets leading through blocks on the clews of the lower topsail and through sheaves on the foreside of the lower yard *c*, and the down hauls leading through fair leaders on the foreside of the quarters of the lower yards, and thence to the cleats on deck. By means of these ropes the topsail is kept taut and fair when set.

When it is necessary to reef, the topsail yard is lowered to the required position, and the several sheets and ropes are hauled taut from the deck, by which operation the effective surface of the topsail is reduced, the upper topsail and lower topsail sliding over each other. Fig. 3 is a foreside view of the topsail so reduced as to be equivalent to a double reefed topsail. When it is necessary to close reef the topsail, the topsail yard is lowered down close to the head of the lower topsail, and the foot of the upper topsail is lowered down close to the lower yard, so that one sail is behind the other, the canvas being consequently doubled, and thereby greatly increasing its strength. Fig 4 is a foreside view of the topsail in the position lastly described. It appears to us that this invention meets the difficulty of reefing in the most simple and economical manner, while at the same time the efficiency of the sail is not in the least impaired.

VARIABLE CUT-OFF STEAM ENGINE.

WE last week gave a summary of a paper read by Mr. Horace McMurtrie, at a meeting of the Massachusetts Institute of Technology, which was reported in an American journal. Mr. McMurtrie has since written to that journal—the "Railway Times"—to make several corrections, which, in justice to the author, we here append. He says:—

Digitized by Google

"In the first place, you report me as stating:—'In relation to economy of fuel, that this engine consumed but 2lb. of coal per hour per horse power.' Although I claim an economy equal to any yet effected by any engine, I did not make such an assertion. Upon this subject I remarked that 'with boilers properly proportioned and set, and with a condensing engine of this make, I had no doubt this result could be obtained'—which is a very different statement. The present consumption of fuel with a non-condensing engine is about 2½lb. to 3lb. The socond error is respecting the reply made to Mr. E. B. Bigelow's questions, which were, that I should state the 'difference in principal between the Corliss engine and the one exhibited.' I am reported as replying that 'the principle of the cut-off was the same in both,' but that 'the eccentric used to regulate the cut-off in the Corliss engine was dispensed with,' etc.! This is all wrong, and the latter part of it an absurdity. My reply to Mr. Bigelow was, that 'the general principle of all variable cut-offs was the same, viz., that the variation in the load, through the agency of the governor, varied the grade of expansion; but that in the Wright engine, the valve gear, being operated entirely by the governor, the eccentric and its appendages used in the Corliss engine' were dispensed with."

TURRET SHIPS FOR COAST AND HARBOUR DEFENCE.

ABOUT eighteen months ago, the Dutch Government, after a long discussion as to the description of vessels which would most efficiently provide for the defence of their own harbours and coast, decided to construct a fleet of armour-clad vessels, some to be of a light draft of water for the navigation of their shallow inland waters, canals, and harbours, others with great speed and good sea-going qualities, to render them available, when necessary, for the defence of any portion of their sea-board. The construction of several of these vessels was entrusted to Messrs. Laird Brothers, Birkenhead. One of these, the "De Steir," was successfully launched at Messrs. Laird Brothers' works, at Birkenhead, on Thursday last, in the presence of Mr. Jansen, under whose superintendence the vessels are being built; Captain Hugenholtz, Commander of the "Prins Hendrik" during her recent cruise; Mr. May, Dutch Consul at Liverpool; M. Von Santen, Mr. John Laird, M.P., and a number of ladies and gentlemen, who took great interest in the proceedings, and in the christening of the vessel, which was gracefully performed by Miss Agnes Laird. "De Steir" is a twin screw iron-clad steam-ram, carrying one turret on Captain C. P. Coles' principle, armed with two 300-pounder 12½-ton rifled guns. After being launched the ram was taken into one of Messrs. Laird's adjoining docks, and as this vessel is of the same class as the Peruvian turret vessel "Huascar," built by Messrs. Laird Brothers, and referred to in the "Times" in an article pointing out the valuable qualities of this description of iron-clad turret-ships for coast defences, a short description may be interesting.

She is a vessel of 1,325 tons burden; length 200ft., breadth 38ft. and depth 19ft.; and her extreme draught of water, when completed for service, will not exceed 15ft. 6in. She is armour-plated with 6in. plates, from 3½ft. below the water-line up to the gunwale, for the greater part of her length, the plates tapering slightly towards the ends. The armour rests on a backing of 10in. teak, and this again on an inner skin of 1in. supported by the framing of the ship. Her turret, which is cylindrical, and constructed on Captain Cowper Coles' principle, is protected all round by armour-plating, which in no place is in thickness less than 8in., increased to 11in. round the ports, the plates resting upon a teak backing of 13in., with an inner iron skin of 1in. As we have said, the turret will carry two 300-pounder rifle guns, having a range of fire from 10 degrees of the line of keel forward and 6 degrees aft, so that she can in rapid succession deliver her fire at almost all points; while the facility with which her twin screws will enable her to turn will make her very handy in action. Her port sills are arranged at a height of 6ft. 6in. above water. The turret, in addition to the usual apparatus for working by hand, is fitted with steam gear, for more rapid movement is necessary. On the main deck is a shot-proof pilot tower, and a poop and forecastle, fitted with supplementary cabins, in addition to excellent accommodation for officers and crew below the main deck, under the protection of the armour. By an ingenious arrangement of hatchways, carried above the main deck, excellent light and ventilation for the below deck cabins is abundantly secured; and ample accommodation is reserved below the water line for magazines, store-rooms, coal bunkers, &c. The ram-stem is of iron and of great strength, projecting about 5ft. at such a depth under the water as to enable her to strike an enemy's ship below her armour plating. This formidable weapon of offence is built solid into her framework, and is so constructed as to resist the shock of the collision. Her machinery, which has been made at the same works, consists of two pairs of surface-condensing direct-acting engines, each of 175-horse power, giving 350-horse power collectively, and are so arranged as to work to a very high indicated power, each pair of engines driving a screw under the counter of about 12ft. 6in. diameter. Her boilers are fitted with super-heaters, and the machinery generally is made in accordance with the new Admiralty specifications for engines of this class. The engines and boilers will be placed on board in the course of this week. It is expected that her speed will be thirteen knots.

Messrs. Laird Brothers have also recently launched for the same Government two of the light draft of water vessels of the monitor class, which are now receiving their machinery and fittings in the same dock as that in which "De Steir" has been placed. They are named the "Panter" and "Krokodil," each carrying one turret, on Captain Coles' principle. The dimensions of the vessels are:—Length, 180ft.; breadth 44ft.; depth, 11ft. 6in.; and draft of water when ready for service, 8ft. 6in. They are armour-plated with 5½in. plates, from 3ft. below the water to the gunwale, reduced at extreme ends to 4½in. The armour rests upon a backing of solid teak, 10in. thick, strengthened by longitudinal webs of iron; and there is an inner skin of iron plates 1in. thick. The deck is secured against the crushing-in effect of a plunging fire, by beams of great strength placed very close together and covered with wrought-iron plates, 1in. thick amidships and ⅞in. at the ends, the deck itself being of teak planks 4½in. thick. The turret is protected by plates 8in. thick, increasing to 11in. at the ports. It carries two 300lb. rifled guns, which can be fired in line of keel forward and within four degrees aft. The monitors have also twin screws, and each will be fitted with two pairs of direct acting engines, each of the nominal horse-power of 70-horse, working collectively to 140-horse power. One important feature of both vessels is, that they are fitted with a double bottom divided into compartments, with contrivances for admitting water ballast, so that the vessels can be put down in the water at pleasure to the extent of one foot lower than their ordinary sailing draft, thus reducing the height of the side, as exposed to the enemy's shot, to 2ft. Each also carries an armour-plated pilot tower, and the base of the funnel is protected by armour-plates a certain height above the decks; while the hull is subdivided by a number of longitudinal and athwartship water-tight bulkheads. The accommodation for 75 to 100 men below deck, irrespective of the deck-house aft is ample, commodious, light, and airy, so that protection and comfort are ensured in that respect, when lying "snug" in the expectation of the enemy. The hatches, conveying air and light to the cabins and berths below deck, are carried 8ft. above the main deck, and their bases are protected by plates placed at sloping angles so as to deflect shot which would otherwise strike the foot of the hatchways.

The "Panter" is far advanced towards completion, and she will probably leave Messrs. Laird's dock in a few days for her preliminary trial trip, after which she will return to receive her gun-slides and guns. The "Krokodil" is also well advanced, and will be completed some time this month. The speed of these vessels, when fully equipped, will be about 8 knots. They are rigged with light pole masts, for signalling rather than for any practical purposes; as they are not intended to carry sails. Both vessels are fitted with light falling guard rails, which, in action, will lie flat on the deck. It is believed that these monitors, by being able to keep close inshore, will be found to be most formidable to any antagonists approaching the coast, for, with small size, presenting but a small object to the enemy, and a light draft of water, they are able to carry guns equal to those for which vessels of the largest class are pierced. These two vessels may be considered as improvements in the Brazilian turret ships "Bahia" and "Laria Barros," built by Laird Brothers, and both of which have been employed in the River Plate, the former as the flag-ship at the recent attack on Humaita.

The fitting-out dock which now contains the ram "Steir" and the sister monitors "Panter" and "Krokodil" is immediately in front of Messrs. Laird's engine and boiler shop and armour-plate sheds, and is within a radius commanded by the 50-ton crane, with which the finished framework of the turrets, weighing thirty tons and more, the machinery and other ponderous masses can be placed on board and adjusted in their place to the greatest nicety. In one of Messrs. Laird's adjoining docks her Majesty's turret ship "Captain," of 4,200 tons, is making rapid progress. She is plated with 8in. plates on a solid teak backing, will carry two turrets, on Captain Coles' principle, each armed with two 600-pounder rifled guns. She will have twin screws, and will be fitted with powerful machinery, giving her a high rate of speed. In another dock, nearly completed, is a composite—wood and iron—gun-boat, the "Teazer," which is to be armed with two pivot 7in. 6½ ton guns. She is one of eight gun-boats which are being specially constructed for service in the Chinese seas.

In No. 3 dock, just laid down, is the lower frame-work of her Majesty's broadside frigate "Vanguard," of 800-horse power, one of the four ships of the "Invincible" class, orders for which have recently been issued by the Admiralty. The Messrs. Laird have been commissioned to build the "Vanguard," in consequence of having furnished the best competitive plan for an iron-clad of any class, in competition with six other private shipbuilding firms. To ensure rapid progress with the work a shed is being erected over the dock, so that the men may not be interrupted in their work by the weather.—"Liverpool Albion."

Legal Intelligence.

COURT OF COMMON PLEAS.

April 21.

(Sittings in Banco, Easter Term, before Lord Chief Justice BOVILL, and Justices BYLES, KEATING, and SMITH.)

THE BRITISH COLUMBIA SAWMILL COMPANY v. NETTLESHIP.

THIS was an action tried at the last Guildhall sittings before the Chief Justice, and was brought on a bill of lading to recover the value of a box containing the fittings of a quantity of machinery, which was sent out to Vancouver's Island. On the arrival of the defendant's ship out there, the box in question was missing. The box had been delivered at the dock side to the defendant's agent to be put on board ship. The plaintiffs sought to recover not only the value of the machinery fittings in the box which was lost, but damages beyond, on the ground that all the other machinery sent out was useless without those fittings. At the trial the plaintiffs recovered a verdict for £3,000 damages.

Sir G. Honyman, Q.C. (with whom was Mr. Lanyon), now moved for a rule for a new trial, on the grounds that there was no evidence of the defendant's liability, or that the box had been placed in the defendant's custody on board the ship, for misreception of evidence, and to reduce the damages.

After a long argument, the Court were of opinion that there ought to be no rule on the first two grounds, but granted a rule *nisi* on the third ground—that the damages were excessive.

Rule *nisi* accordingly.

Correspondence.

DEFENCE OF FORTRESSES.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—In my last letter on this subject, the thirty-third line in the second column should be—

"Q 1 *l.*, *r. t.* . . . Q 1 left, right triangle."

And I beg to make use of this opportunity, by remarking that I gave the described subdivision of the range field of the guns merely as an example, and that most probably other and better methods could be devised.—I am, Sir, yours, &c.,

G. J. GÜNTHER.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

SCRUTATOR.—If you will compare the descriptions of Ormerod's and Aytoun's safety shackles, you will find that Aytoun's disengages the cage from the winding tackle, but drops it, whilst Ormerod's cage, at the moment it is disengaged, is suspended, and cannot fall. This is a distinction with a material difference.

Meetings for the Week.

MON.—Royal United Service Institution.—Major Scaky, R.E., on "Army Organization—Our Infantry Forces and Infantry Reserves," at 8.30 p.m. A discussion on this, and Major Bevan-Edwards' paper, entitled "An Organization for the Army of England," will be taken afterwards.

TUES.—The Institution of Civil Engineers.—Discussion upon the papers on "Irrigation in India and in Spain," at 8 p.m.

Royal Institution.—Dr. M. Foster on "The Development of Animals," at 3 p.m.

THURS. — Royal Institution. — Professor Odling on "Chemical Combination," at 3 p.m.

FRI.—Royal Institution.—Annual Meeting at 2 p.m. Mr. F. T. Palgrave on "How to Form Good Taste in Art," at 8 p.m.

SAT. — Royal Institution. — Professor Odling on "Chemical Combination," at 3 p.m.

Naval, Military, and Gunnery Items.

IT was announced at Chatham, on Wednesday, that Captain W. K. Hall, C.B., will retain his present appointment of Superintendent of Sheerness dockyard, by order of the Admiralty, until his promotion to flag rank.

THE "Minotaur" the other night was run into by a sailing ship, which wrought havoc with his boats, and the excuse of the skipper was at least ingenious. "I saw three masts, and thought I had cleared the ship," said he, "and put down my helm. Who, the deuce, could have thought there were five-masters knocking about?"

INTELLIGENCE from Japan announces that a boat's screw and officers belonging to the French man-of-war, "Dupleix," have been massacred at Osaca. The Japanese Government had offered satisfaction for the outrage, but all the foreign ministers, excepting the representative of Great Britain, had hauled down their flags.

ON Wednesday last, Vice-Admiral Sir Baldwin W. Walker, K.C.B., Naval Commander-in-Chief at the Nore, made an official final inspection of the screw frigate "Bristol," 31, 600-horse power, Capt. F. W. Wilson, on her completion as a training ship for naval cadets. The "Bristol" is under orders to proceed from the Nore to make her first cruise for the summer season, calling in at Spithead, on her way down Channel, for final instructions.

AN Australian paper states that the Duke of Edinburgh, after leaving Sydney, visits New Zealand, Tahiti, Honolulu, Callao, Valparaiso, Falkland Islands, Monte Video, Rio, Demerara, Trinidad, Tobago, Grenada, and Barbadoes, and thence home to Portsmouth, where he is to arrive in January, 1869. This is no yachting voyage, considering the "Galatea" will round Cape Horn in September. The "Galatea" has been docked at Sydney, and received a new false keel, and repairs to her new screw shaft bearing.

THE quarterly meeting of the Royal Naval Benevolent Society was held on Tuesday, at Willis's Rooms, King-street, St. James, under the presidency of the Earl of Lauderdale. The balance-sheet showed that the receipts had amounted to £1,367 15s. 5d. during the last quarter, and the expenditure had been £679 12s. 0½d., leaving a balance in the hands of the bankers of £688 3s. 4½d. The report of the special committee appointed at the last quarterly court to revise the by-laws was read, but it was resolved to adjourn the consideration of it for a month. A sum of £563 was voted for grants during the ensuing quarter, and the proceedings terminated.

SOME idea of the difficulty experienced by an army in traversing a mountainous country may be gathered from the fact that it took eleven hours for a small portion of the 1st Brigade, under Sir Charles Staveley, to make a march of under seven miles in Abyssinia. The descent of about 800ft. or 1,000ft. from the halting place at Belago to the plain beneath caused the greater part of the delay. With all the assistance of the infantry, numerous breakdowns occurred, owing for the most part to the miserably faulty condition of the pack-saddles with which the mule trains from India are equipped.

IT is stated in the American "Army and Navy Journal" that the "Wampanoag" is to be placed out of commission, because "she is found to be not a proper vessel for a cruiser during peace times, on account of the cost of running her." According to all accounts this vessel must be something of a white elephant. It cost a huge amount to build her, and while the expense of running her in peace times would be ruinous, her battery is too light to make her formidable in case of a war. In addition to this, she can only carry coal enough for six day's full steaming, while we are assured that, on her recent trial trip, it was found she would not tack under sail. Putting all these facts together, we could hardly wish a hostile power a worse fate than to be compelled to build and keep at sea a fleet of "Wampanoags."

Miscellanea.

A FREE library, containing about 10,000 volumes, was opened in Nottingham on Monday.

THE number of visitors to the Patent Office Museum for the week ending April 18, was 12,161; total number since the opening of the museum, free daily (May 12, 1858), 1,286,586.

A FIELD of Italian grass (a species of seed recently adopted in Surrey) is now being cut at Streatham, for green food for cattle, and the crop is fully one month earlier this year than at any previous spring since its introduction into this country.

ONE of the French law courts has just had to decide a singular question. A person recently deceased had left by will to a poor needlewoman, during her life, soup and boiled beef for every day in the year. The point to be established was the sum which such a legacy represented. The Tribunal has fixed it at 1f. 25c. per day.

IN order to approach the railway bridge over the Mississippi, connecting Dunleith with Dubuque, the Illinois Central Railway have found it necessary to undertake the boring of a tunnel 900ft. long, through solid rock. This formidable undertaking has been let to the Rock Island contractors, and they have already commenced operations.

AT the meeting of the Royal Geographical Society on Monday next, Sir Roderick I. Murchison, Bart., president, will occupy the chair. It is anticipated that the meeting will be very crowded on account of the vast interest which is felt in the despatches and letters which have been received from Dr. Livingstone, and which then will be read.

SEVERAL meetings of men employed in the works throughout the iron manufacturing districts have been held, for the purpose of determining what course shall be taken if the masters enforce the reduction of which they have given notice. At most of the meetings it was resolved to resist the reduction, but at some of them the workmen did not come to any definite conclusion.

AT the Seventh General Meeting of the Eleventh Session of the Institution of Engineers in Scotland, held on Wednesday, March 11, 1868, Mr. Jas. M. Gale, C.E., president, in the chair, the following candidates for admission to the Institution were elected as members:—Mr. S. S. G. Copestake, Glasgow Locomotive Works, and Mr. James Goodfellow, Caledonian Railway Works, St. Rollox.

THE visitors to the South Kensington Museum during the week ending April 18, which, being Easter week, was free, were 31,800, the museum being open each day from 10 a.m. till 10 p.m. To the National Portrait Exhibition, by payment, 3,441; Total—35,241. Average of corresponding week in former years, 24,692; total from the opening of the Museum, 7,329,874.

THE material advance in the copper standard and the advance of £4 in the tin standard which have occurred within the last few weeks, have caused considerable improvement in Cornish mining, and several concerns are being worked with increased vigour. There is no longer any surplus adult labour, and the supply may be said to be unequal to the demand. Full time is now the rule, and the mining districts are generally assuming a healthy appearance.

WE, "Times," are informed by the Italian Consul-General that the Italian Ministry, desirous of facilitating as much as possible the transport of the luggage of passengers passing by Susa, have made arrangements with the Central Italian Railway Company by which the baggage will not in future be examined, but merely *plombé* (sealed), to preserve its identity, and it will be forwarded to its destination under bond of the railway company. This rule will apply to such luggage as passengers may have with them.

YESTERDAY week, two labourers were clearing away the slag from the furnace at the Wigan Coal and Iron Company's Works, which had to be done by blasting. One man was holding the rammer and the other striking the blows, when the charge exploded, and the former had his right hand blown clean off, his left hand terribly shattered, and his right arm broken in several places. Amputation of both limbs was necessary, and both men lie in a precarious condition.

SLIGHT shocks of earthquake continued to be felt at St. Thomas, the heaviest of which is thus referred to in the "Tidende" of March 18th:—To-day exactly four months have elapsed since our island was visited by the terrific earthquake on the 18th of November last year, and yet we have to record another shock which occurred yesterday morning, at fifteen minutes after seven. The duration was about thirty seconds, but the vibrations felt were rather more horizontal than vertical, and not so powerful as on the 18th of November. It was observed that the sea receded several feet. No particular damage occurred further than the bursting of a few old condemnable wall-works.

FROM the report of the Minister of Public Works for 1869, we learn that on December 31, 1868, 48,200,000fr. will have been expended on the Mont Cenis tunnel. Eight millions more are to be spent in 1869. If the expenses continue at the same rate, and if the tunnel be completed, as is hoped, in 1871, its entire cost (without reckoning the two bits of railway that are to connect it with Susa and St. Michael, and which will be enormously costly) will not fall far short of £3,000,000 sterling. A portion of this will be borne by France, as is only just, for, after Italy, she is assuredly the country that will gain the most by the completion of the colossal work.

AN additional statue has now been placed at the principal entrance to the members' private arcade in New Palace-yard, viz., one of King John. There are now three statues placed in the front of this arcade, viz., Alfred the Great, William the Conqueror, and King John. The remaining three vacant niches will shortly have statues placed in them. These statues are of Portland stone, and stand 6ft. 6in. high. The bronze statue of the late Sir Robert Peel, which stood for some time uncovered at the central entrance to New Palace-yard, having been removed on account of the ineligibility of the site, will be shortly placed on a granite pedestal at the entrance to New Palace-yard fronting Parliament-street and Great George-street.

THE Lille journals reports a terrible catastrophe in that city. A few days since the large steam-engine boiler—60-horse power—in the establishment of MM. Dequoy and Co., spinners, exploded with a frightful crash, spreading death and destruction around. The workpeople rushed out as best they could, in great consternation. But the calamity did not end there, as the tall chimney of the factory, which was upwards of 60ft. high, fell in the course of a few minutes afterwards, overthrown, no doubt, by the shock of the explosion. The people of the entire neighbourhood were frightfully alarmed. The material loss cannot as yet be computed, but six of the workmen were killed, some of them fathers of families, and eight wounded more or less grievously. The cause of the explosion is thought to have been a sudden flow of water into the overheated boiler.

ON Saturday last a second show of spring flowers was held in the gardens of the Royal Horticultural Society at South Kensington. These displays are distinct from the great exhibition of the season, and bear a valuable character of their own. The bulbous and other varieties of plants which are reared in this country under glass during winter, as well as the early spring flowers, are now of themselves sufficient to furnish a show, without including the forced blooms which are produced naturally later. The prizes on Saturday were mostly for spring flowers proper, but besides these, several special premiums were given for roses, and a good show of this flower was contributed.

WHILE workmen were digging for the site of a new building in Trongate, Glasgow, a few days ago, they came upon a number of coins, embedded in the clay a few inches under the surface. It is believed that there were about 100 pieces in all, but they had got dispersed and carried off by the men before anything was said of the matter. By considerable effort, however, eighty of the coins have been recovered, and of these nearly thirty are clearly recognizable as Elizabethan. All of them are much worn, but the impression can, in almost every instance, be readily made out. There are six or eight of King James's Irish pieces. All these bear traces of long circulation, and, in some cases, the irregularity of the edges would seem to indicate that they had been clipped. The coinage of Charles is as numerously represented as that of Elizabeth. Of the Scotch 40-penny pieces two or three are in very perfect condition. Others have been a good deal knocked about, but the small size and thinness of this coin seems to have saved it from being "sweated." The whole of the pieces seem to have been coined by the old process of hammering. The edges bear no trace of milling, and the impressions in some cases seem to have been imperfectly made. A shilling of Charles, for instance, looks as if, being twice struck, its position had been shifted between the blows.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—2768, 2772, 2773, 2777, 2780, 2782, 2792, 2825

BUILDINGS AND BUILDING MATERIALS—2791

CHEMISTRY AND PHOTOGRAPHY—2760, 2785, 2801, 2816, 2828

CULTIVATION OF THE SOIL, including agricultural implements and machines—2763, 2804

ELECTRICAL APPARATUS—None.

FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2757, 2767, 2774, 2775, 2790, 2802, 2803, 2815 2833, 2841, 2843

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—2762, 2765, 2766, 2834

GENERAL MACHINERY—2759, 2770, 2779, 2787, 2788, 2793, 2794, 2799, 2800, 2809, 2811, 2814, 2824, 2826, 2830, 2836, 2842, 2845

LIGHTING, HEATING, AND VENTILATING—2820

METALS, including apparatus for their manufacture—2789, 2813, 2819, 2832

MISCELLANEOUS—2761, 2764, 2769, 2776, 2781, 2783, 2784, 2805, 2807, 2808, 2817, 2822, 2823, 2827, 2829, 2838, 2839, 2840, 2844, 2847, 2850

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2771, 2795, 2796, 2797, 2810, 2821, 2831

SHIPS AND BOATS, including their fittings—2798, 2843, 2849

STEAM ENGINES—2812

WARFARE—2778, 2837, 2846

2756 E. P. ALEXANDER. *Improvements in the manufacture of cast steel, and in furnaces to be employed therein.* (A communication.) Dated October 1, 1867.

This invention is not described apart from the drawings. —Patent completed.

2758 H. A. BONNEVILLE. *Improvements in machinery for spinning wool and other fibrous materials.* (A communication.) Dated October 1, 1867

This invention is not described apart from the drawings. —Patent completed.

2759 J. G. JONES. *Improvements in apparatus for hauling or winding ropes.* Dated October 1, 1867.

Here the patentee constructs a pulley or drum with nipping instruments to hold a rope securely when it is passed only partly around it, in the following manner:—He forms the pulley or drum with a groove passing round its periphery; the groove has inclined sides, and so becomes narrower as it proceeds towards the centre of the pulley or drum. Against the sides of this groove sliding pieces are arranged; there is a number of them around the circumference of the pulley or drum, and each pair of sliding pieces is fitted with a spring pressing them outwards from the centre of the pulley or drum. Lips on the sides of the groove limit the outward movement of the slides, and keep them in their places, and suitable stops in the groove prevent them moving laterally. When a rope is drawn tightly around the pulley or drum, it bears against the slides, and presses them inwards, overcoming their springs, until the incline of the groove causes the slides to tightly nip the rope, and as the pulley or drum revolves, it hauls on the rope and winds it forward.—Patent completed.

2760 G. ALLIBON and A. MANBRE. *Improvements in apparatus applicable to the conversion of cereal and vegetable substances into saccharine matter, in treating and purifying saccharine substances extracted from malt, fruits, and vegetables, in treating fatty matters, and in the manufacture of chemical products.* Dated October 1, 1867.

Here the patentees construct a close vessel, usually of wrought or cast iron, and of a cylindrical form; it is built up in segments, and, by preference, each segment is made semi-cylindrical, and of a convenient length; it is made with external flanges all round, and the flanges of the several segments fit accurately together, and are secured the one to the other by screw bolts. The segments are each covered internally with a sheet of lead, tin, copper, brass, silver, platinum, or other lining metal which will not act injuriously on the liquid with which the boiler or vessel is to be worked, or be injuriously acted on thereby. The edges of these sheets are turned down over the flanges of the segments, and when the segments are fixed together, the lining sheets are firmly clamped between the flanges. The ends of the boiler or vessel it is preferred to make hemispherical, and also in segments; usually they are made of cast iron, and strengthened with suitable ribs, whilst the cylindrical part of the boiler they prefer to make of wrought iron.—Patent completed.

2761 J. L. FIELD. *Improvements in candles, and in moulds for moulding the same.* Dated October 1, 1867.

This invention is not described apart from the drawings. —Patent completed.

2762 G. F. GREEN. *An improved combined billiard and dining or general table.* Dated October 1, 1867.

The object here is to combine with a dining or general table a billiard table, so that in private houses, for example, a separate room for a billiard table is dispensed with. For this purpose, upon the framework of an ordinary table the inventor mounts a billiard table capable of being raised up from such framework the required height by a worm shaft running from end to end of the frame, and geared into worm wheels, which latter are connected to jointed levers connected to lugs on the under side of the billiard table. The dining table is formed by loose covers fitted on to the edges of the billiard table, and when it is required to use it as a dining or ordinary table, such covers being placed on, the billiard table is lowered on to the framework, and it is then the requisite height for that purpose.—Patent abandoned.

2763 W. MITCHELL. *Improvements in apparatus for sharpening the blades of knives employed in mowing and reaping machines.* Dated October 1, 1867.

This invention relates, first, to an apparatus driven by gearing or manual labour; and, second, to an apparatus to be used in a similar manner to a file, both being designed for sharpening the angular knives employed in mowing and reaping machines, and particularly for entering and sharpening the inner angles or corners of such knives. The improvements consist, first, in the use and adaptation of a rotating disc or circular plate mounted on a shaft inclined from the vertical so as to place the disc at an angle upon the disc; a covering of emery composition is laid tapering from the periphery towards the centre, and the whole is driven by strap and pulley or gearing. The peculiar position and form of surface and narrow periphery of this emery-covered disc enables the operator to grind or sharpen each edge of the angular knives from the "point" to the "root" evenly, without leaving the inner angle unground, as by the present method employed for sharpening. Second, the improvements consist in the adaptation and use of a similar tapered emery surface, which is to be placed on a metal or wood foundation, and shaped and used like a file, one side of the emery file being narrow, and the other wide, the back or foundation being also tapered (the cross section being like a wedge), and the "tang" or handle being placed out of the centre and nearer one side of the file. These emery files thus formed are to be used in pairs, "right and left-handed," and are specially adapted for entering the angles and sharpening the said angular knives.—Patent completed.

2764 W. E. GEDGE. *Improvements in match boxes.* (A communication.) Dated October 1, 1867.

The outer appearance of these match boxes is, in every respect, similar to that of other boxes, but an inside arrangement isolates all the matches, and holds them in such a way that they cannot fall out. This arrangement is obtained by two sheets of sand or emery paper, previously undulated or corrugated; in bringing these two sheets together they form a series of tubes, each of which lodge a match; these latter being placed in them with the phosphorated part downwards, in such a way that, to withdraw them from their cells, a certain amount of traction must be exercised, and this traction will cause friction, and thus the match will issue from its case alight.—Patent abandoned.

2765 R. FLETCHER. *A new or improved castor.* Dated October 1, 1867.

This invention relates to castors for furniture or other purposes, and consists of a cup and ball and bearing plate. The ball is spherical and the cup flanged at the top, and open at the bottom. The diameter of the ball is a little greater than the depth of the cup, so that, when the bearing plate which closes the top of the cup is fixed thereto, the ball projects through and below the opening before mentioned in the bottom of the said cup. The covering and bearing plate is fitted with three or more rollers which rest upon the ball when the latter is placed in position. These rollers, when three are used, are so arranged that their lines of axes form an equilateral triangle, and when more than three are used their respective axes form a regular polygon. Being thus fitted, the ball is free to rotate in any direction in which the article supported thereby is moved.—Patent completed.

2766 T. E. CLARKE. *Improvements in the construction of bedsteads and mattresses.* Dated October 1, 1867.

This invention is not described apart from the drawings. —Patent completed.

2767 W. and S. SMITH. *Improvements in the construction and working of back rollers, carriers, and carriages in drawing, roving, and spinning machinery for wool, hair, silk, flax, and other fibrous substances.* Dated October 2, 1867.

This invention has for its object the more even working or winding backwards and forwards of the back rollers, carriers, and their carriages, on the above-named machines than any other modes hitherto employed; it is also a certain method of keeping the rollers true or straight during the alteration of the "ratches" from one length to another, and, consequently, effects a considerable saving in time and labour, as any one person can with ease make the alteration. By the application of these motions the back rollers and carriers are kept straight, or in an even line, as all parts must move simultaneously, thereby preventing a breakage in the pins and couplings; also avoiding a great amount of wear and tear in the couplings; consequently, there must be a considerable saving in the power required to drive these parts of the machinery. In applying this invention to the back rollers (and their carriages) of a spinning or "dandy" roving frame, for example, the patentees provide each back roller carriage with a screwed nut passing downwards through a slot in the carriage stand, having working through it a screw mounted in the carriage stand below in a line parallel with it; the outer end of each screw is furnished with a small bevel wheel gearing with a similar wheel keyed upon a shaft running at right angles to the screws for the whole length of the machine. This shaft is carried in suitable bearings, and is provided at one end with a winch handle, by means of which it can be turned. It will be evident that upon turning this shaft, the bevel wheels will cause all the screws to turn simultaneously, and thus advance or withdraw all the back roller carriages with their rollers at the same time, and at the same speed. The above is but one of the arrangements described in the specification.—Patent completed.

2768 R. H. TAUNTON. *Improvements in the manufacture of strip or sheet iron for certain purposes.* Dated October 2, 1867.

This invention relates to the making of strip or sheet iron for the manufacture of tubes for locomotive, marine, or other tubular boilers, or tubes required to be flanged or expanded. Hitherto a difficulty has existed in the manufacture of tubes for the purposes named, even when extra quality of iron is used, to permit the operator without fracture to spread the ends outward, so as to form flanges, an operation essentially important for securing iron tubes to such boilers; and this hitherto difficulty or defect has arisen from the fibrous course of the iron on the outsides of the sheets or strips being entirely in its lengthway direction. The object of this invention is to overcome this defect, which the patentee does by so arranging and building up the pile of iron from which he purposes rolling out the finished strip or sheet that, instead of the grain of the finished tube being in its lengthway course, it is so arranged that a sufficient portion of the grain is distributed by preference on both sides in a transverse direction, or more or less oblique, thereby permitting the tube to be hammered, beat, enlarged, and spread over into a flange without splitting or cracking on its lengthway or other direction under this operation.—Patent completed.

2769 F. PARKES. *Improvements in the manufacture of certain descriptions of nails.* Dated October 2, 1867.

The patentee claims the manufacture of nails known as "clasp," or such like description of nails requiring small heads and sharp points, in the manner substantially as described, that is to say, such nails being cut from the ends of metal strips rolled thick in the middle and thin at the edges.—Patent completed.

2770 A. C. HENDERSON. *Improvements in sewing machines.* (A communication.) Dated October 2, 1867.

The object here is to produce with one machine all the various species of stitches at present known, that is to say, the chain, the lock, and the shuttle stitch. The apparatus, as usual, is mounted on a table standing on cast-iron feet, and supported by a cast-iron plate, with openings therein for the play of the various parts. The details of the invention, as set forth in the specification, are too voluminous to be produced here.—Patent abandoned.

2771 C. J. APPLEBY. *Improvements in railway fastenings.* Dated October 2, 1867.

This invention consists in the application of steel collars of suitable form to the necks of bolts or railway fastenings, and the object of the invention is to prevent the great wear on bolts or fastenings caused by vibratory contact with steel or other rails.—Patent abandoned.

2772 C. RITCHIE. *Improvements in mechanism or arrangements applicable to steam boilers and their furnaces, the said mechanism or arrangements being especially applicable to those boilers and their furnaces with which gas is the combustible used.* Dated October 2, 1867.

This invention consists in the adoption in steam boilers of arrangements of mechanism whereby a float or other equivalent contrivance may be used in connection with a damper, or other such like appliance, in or appertaining to the flue or passage for carrying off the products of combustion and heated air, thus controlling the generation and pressure of steam, with suitable provision for regulating in an automatic manner the supply (of gas for boilers heated by gas), and of air and water to boilers heated by gas or other means.—Patent abandoned.

2773 J. H. NELSON and T. BRIGGS. *Improved means and apparatus for heating the feed water of steam boilers and other general purposes requiring heated water.* Dated October 2, 1867.

Here, in the main flue, beyond the boiler or boilers, the patentees place an auxiliary flued boiler, with a certain number of tubes or pipes in the flue of the said boiler, either in a horizontal or vertical position, according to circumstances, the size of the boiler and number of tubes being dependant upon that of the amount of heated water required. This boiler or economizer is fitted with the usual fittings of boilers, some of which will require to be extended through the brickwork of the flue, so as not to impair the efficiency of the latter. The economizer is filled with cold water, and a pipe is connected to the boiler or boilers. The fire being lighted, the flames and heat, after passing through and round the boiler or boilers, on their way to the chimney stack, surround and pass through the economizer, heating the water therein. The water so heated is admitted to the boiler or boilers, and a continuous supply maintained, all cold water after the first feed passing through the adjunct or feeding boiler, which, as it will have been seen, is heated by the waste heat on its passage to the chimney stack. The other vessels referred to in the title of the invention are dye pans and vats and other vessels used in manufactories where heated water is required, the water being drawn direct from the economizer instead of from the steam boiler or boilers (as is now the case) with economical results.—Patent completed.

2774 M. WRIGHT. *An improved species of fabric.* Dated October 2, 1867.

Here the inventor produces a fabric lustrous, and having a mingled appearance, the mingling being more regular than in fabrics known as "Debeges," and those of a similar class. He effects this by weaving what is known as Grundrell warp (consisting of two colours of cotton twisted together) with what is known as melange weft.—Patent abandoned.

2775 G. RAMSDEN, L. WEBSTER, and J. WALKER. *Improvements in fulling machines.* Dated October 2, 1867.

This invention consists in the employment of a flanged cylinder, and two, three, or more pressing rollers applied thereto at different points of its circumference, betwixt which the fabrics are caused to pass in a crimpled or crumpled state as they issue from the ordinary squeezing rollers, or from a conducting spout into which they are pushed, and thereby crimpled or crumpled.—Patent abandoned.

2776 F. J. JEFFERY. *Improvements in urinals.* Dated October 2, 1867.

This invention consists, first, in supporting the urinal proper on or by hinges or trunnions, or their mechanical equivalents, so that it can be folded up when out of use, and made to lie flush with the wall, washstand, or other structure in which it is fitted, and practically be invisible, presenting only its side or back, which can be ornamented in any desired manner. Second, in combining with urinals supported according to the first part of this invention a water supply pipe with a valve or tap therein, so that the folding down into position for use shall open the valve or tap, and allow water to flow, and the folding up close of such flow; and, third, in making urinals constructed according to the first or both the first and second parts of the invention self-emptying and closing. For this purpose the patentee forms a receptacle at the back of the urinal proper into which the liquids flow. When these reach a certain weight, the projecting part is overbalanced, the contents discharged at the back, and the flow of water shut off.—Patent completed.

2777 C. MACE. *Improvements in marine steam boilers.* Dated October 2, 1867.

Here openings are made in the sides of the boiler, and through the water spaces between the tubes, by the openings, a cleansing tool can be introduced laterally between the tubes, so as to clean in between them horizontally, and this in conjunction with cleaning them from the top as heretofore practised ensures the effectual removal of the scale and deposit from every part of the tube plate, and

Digitized by Google

from every part of the tubes. These side openings into the boiler are closed with doors or covers when the boiler is at work.—Patent completed.

2778 H. HASCHKE. *Improvements in breech-loading fire-arms.* (A communication.) Dated October 2, 1867.

This invention relates to an arrangement by which a breech block is drawn back and raised or turned upon a hinge, and the hammer by the same movement cocked or half cocked, by means of a lever at the side of the gun, provided with a knob for moving it. The invention also relates to an arrangement for extracting the empty cartridge case. Reference to the drawings is necessary for a clear description of the invention.—Patent completed.

2779 W. R. LAKE. *Improvements in machinery for sewing boots and shoes.* (A communication.) Dated October 2, 1867.

The object here is to produce sewing mechanism by which soles and welts can be united to the other portions of boots and shoes. The sewing mechanism is so made and arranged as to imitate in its operations the motions of the hand-in-hand sewing. The perforations through which the needle goes are made by an awl which recedes as the needle advances, the awl and needle being hung point to point on separate spindles or axes, or on the same axis if desired. The work is placed on a last, which is held adjustably in a last holder, and this last holder is movable on a vibrating or adjustable table, which is pressed upwards by a weighted lever, so as to press or bear the work constantly against the sewing mechanism, or against the sewing gauge. The frame which carries the sewing mechanism is made to vibrate on a weighted lever, instead of the table, if preferred. The sewing mechanism is combined with devices for stripping the leather from the awl and needle, and both the awl and the needle are operated by means of cam grooves or cams. The feed is produced by means of a feeding awl which has two movements, a vertical movement and a reciprocating lateral movement, and in conjunction with the feeding awl there is a feed dog which is connected to the same lever or arm that carries the feeding awl, the said dog having a blunt edge which rests in the usual "channel" made in the sole of a boot or shoe to receive the stitches, and the feed dog consequently serves to guide the work. The said feed dog has no vertical movement, but only a reciprocating lateral movement, and it serves also as a gauge for the work to rest against.—Patent completed.

2780 W. SPENCE. *Improvements in, and applicable to, ovens, boilers, and other apparatus in which heat is employed.* (A communication.) Dated October 3, 1867.

This invention has for its object the economy of fuel and labour, with the maintenance of an increased regularity of temperature, and consists in the adaptation and application to ovens, boilers, and other apparatus in which heat is employed, of an endless tube disposed in a coil or coils, in such a manner as to be capable of receiving heat from a furnace or fireplace, and through which heated water is caused to circulate.—Patent completed.

2781 R. DICK. *Improvements in heating blast for smelting and other furnaces, and in the apparatus or means connected therewith.* Dated October 3, 1867.

Here the waste gases of blast or smelting furnaces, in place of being allowed to escape into the atmosphere, are carried into a pipe or duct situated in any convenient position, the pipe or duct being surrounded by a series of annular chambers into which the blast from the blowing engine is led. On passing into the first annular chamber the blast escapes from it into the second annular chamber by an orifice situated at the side opposite to that from which it entered, and in passing through the series of chambers it continues to escape and enter them at alternate sides; thus a circulation of the blast around the heated pipe or duct is effected, and the blast becomes the recipient of the heat contained in the escaping gases. The blast after being heated is led from one of the chambers by a pipe into the tuyeres.—Patent abandoned.

2782 H. D. POCHIN and E. HUNT. *An improvement in the construction of furnaces, flues, and vessels which are subjected to high temperatures.* Dated October 3, 1867.

This invention consists in the use of chrome ore in the construction of furnaces, flues, and vessels, or such parts thereof as are subjected to intense heat.—Patent abandoned.

2783 G. P. DODGE. *Improvements in india-rubber mats.* Dated October 3, 1867.

This invention relates, chiefly, to mats for cleansing the feet, formed of strips of india-rubber interwoven or plaited together, and afterwards united by vulcanizing, and consists in using twisted or spiral strips instead of the flat strips hitherto employed.—Patent abandoned.

2784 W. E. GEDGE. *A portable laboratory, specially intended for photographic excursions.* (A communication.) Dated October 3, 1867.

Reference to the drawings is essential for an intelligible description of this invention, unless we devoted more space to it than we can here afford.—Patent abandoned.

2785 A. M. CLARK. *Improvements in the treatment of cotton and other fibrous materials used in dentistry.* (A communication.) Dated October 3, 1867.

This invention relates to an improved treatment of cotton or other fibrous materials, to be used for dental plates more particularly, and consists in mixing with cotton, flax, hemp, or other fibrous material which has been previously dissolved or treated with acids, as is now done in the making of collodion and gun cotton, shellac, or other equivalent material, with or without suitable colouring material in a state of solution, when the mixture is then dried on a glass or other surface.—Patent abandoned.

2786 E. B. DE RICHEBOURG. *A new and useful mode of advertising.* Dated October 3, 1867.

Here the inventor avails himself of the external and internal surfaces of all kinds of small boxes or cases of wood, cardboard, and other appropriate materials in daily use, for the purpose of containing various articles—such as lucifers, pipe lights, pens, wafers, sealing-wax, perfumery, blacking, preserved fruits, or biscuits—and which said surfaces he proposes utilizing by printing or fixing thereon advertisements of other persons than the manufacturers or vendors of the said goods.—Patent abandoned.

2787 G. TOWNSEND. *An improvement or improvements in the manufacture of machine needles.* Dated October 3, 1867.

This invention consists, first, in making machine needles with three or more longitudinal grooves, instead of two only, as at present employed. The patentee prefers to use three grooves, the third being situate just below the shank of the needle; the advantage of this third groove is that it receives the sewing material and insures the formation of the loop; or, to obtain the same result with two grooves only, he forms the back groove in different depths of sinking.—Patent completed.

2788 G. MELLOR. *Improvements in machinery for the manufacture of nails and spikes.* Dated October 3, 1867.

The patentee claims, first, the construction and arrangement or combination of the parts of feeding rolls for feeding the rod of iron into the machine, and the means of operating the said rolls, substantially as described and illustrated in the drawings. Second, the construction and arrangement or combination of the parts of the eccentric rolls and racked slides for gripping the rod during the heading process for pointing the nail or spike, and for preventing the lateral spreading of the nail or spike, and the means of operating the said rolls and slides, substantially as described and illustrated in the drawings. Third, the construction and arrangement or combination of the parts of the heading tool, and the means of operating the said heading tool, so as to make it act also as a stop, substantially as described and illustrated in the drawings. Lastly, the general arrangement or combination of the said feeding, gripping, pointing, and confining parts, and the cutting-off tools into a machine, substantially as described and illustrated in the drawings. We cannot here devote space to a description of the details of the arrangements for carrying out the invention.—Patent completed.

2789 A. T. BECKS. *Improvements in the utilization of Bessemer steel scrap.* Dated October 3, 1867.

The patentee claims treating the said scrap in a blast furnace of the kind called a lumping or charcoal fire, either with or without the addition of lime or chalk, substantially as described.—Patent completed.

2790 T. SAGAR and T. RICHMOND. *Improvements in looms for weaving.* Dated October 4, 1867.

This invention relates to the taking-up motion with a single positive taking-up roller. The novelty consists in an improvement in the method of drawing the ratchet wheel, or other wheel used for the like purpose. The inventors propose to use, instead of the ordinary catches or clicks, a number of thin metallic plates which will require no adjustment whatever for length; the thickness of the plates determines the motion of the ratchet wheel; and the motion of the plates which work the ratchet wheel is governed by the varying diameter of the cloth on the cloth beam by connecting rods, levers, or eccentrics, or other means. They also regulate the letting-off motion on the yarn beam in a similar manner. The invention relates also to the "weft fork" and grid. They propose to substitute for the ordinary weft fork (which has heretofore been made with the prongs open at the ends) one of a similar kind, with the exception that, instead of the prongs being open at the end, they are closed like a grid. They also propose to make the grid in the slay project so as to allow the weft fork to work through it.—Patent abandoned.

2791 S. JOHNSON. *Improvements in machinery for moulding, perforating, and pressing bricks and other articles.* Dated October 4, 1867.

This invention is not described apart from the drawings.—Patent completed.

2792 H. PINKUS. *Methods of constructing steam generators for engines, new furnaces connected therewith, and the mode of working them with machinery, in combination with the uses to which they are applicable.* Dated October 4, 1867.

This invention is not described apart from the drawings.—Patent completed.

2793 A. FORD. *An apparatus for assisting swimming.* Dated October 4, 1867.

Here the inventor provides a glove to be worn on each hand, between the fingers of which is placed a material which, when the hand is extended, shall represent a membrane, filling up the natural spaces between the fingers and the forefinger and thumb, and which forms folds between the fingers when they are approximated to each other, after the manner of a duck's foot.—Patent abandoned.

2794 J. GUTMANN. *Certain improvements in sewing machines.* Dated October 4, 1867.

This invention is not described apart from the drawings.—Patent completed.

2795 W. SMITH. *Improvements in points or switch indicators used on railways.* Dated October 4, 1867.

This invention relates to point or switch indicators for showing to the signalman and driver of an approaching train the position of the points or switches, for the purpose of preventing accidents. The inventor employs in connection with the ordinary semaphore signal or indicator an additional arm, which he calls the danger arm, and prefers that it should be on the right-hand side of the indicator pillar or post when the tongues of the points or switches are not properly open or closed for the main or branch lines. To the rod or stretcher that works the points or switches he joints one end of a connecting rod, the other end of which is jointed to a lever, to the top of which is jointed a bar, frame, or connecting rod having slots at each end, in which slots are placed pins or studs fixed to short arms of double levers, the long arms of which are jointed to a vertical rod extending to the upper part of the pillar or post, and connected to the lever of the additional or danger arm so that a very slight movement of the switch is sufficient to place the arm in its horizontal or danger position. At night he uses a lamp, inside of which is placed a slide or frame containing coloured glasses, which are moved between the flame and the lens of the lamp by means of a lever connected with the rod of the ordinary arm, thus indicating the position of the points or switches.—Patent abandoned.

2796 J. OFFORD. *Improvements in railway and other carriages and various parts of the same.* Dated October 4, 1867.

These improvements consist, first, in the application of india-rubber to the axle boxes of carriages. The patentee fixes two metal flanges to the axle box some distance apart from each other, and he then fits metal sockets covered with india-rubber on their outsides between the two metal flanges; these sockets are to hold the spokes of the wheel in their places. The invention consists, second, in making axle blocks of metal and india-rubber combined together in the process of vulcanizing. The patentee takes two plates of metal with holes made in them, or lugs to receive the bolts to fix them to the axle and spring; he then takes india-rubber, prepared for the purpose, and of the desired thickness, and places it between the two metal plates; he then subjects the two plates with the india-rubber between to a process of vulcanizing, which will cause the two plates of metal to adhere firmly to the india-rubber. The invention consists third, in making the glass frames of carriages of metal and fixing india-rubber or other soft material round their edges to prevent their rattling against the window frames. The invention consists, fourth, in preventing the rattling of carriage lamps. He makes metal sockets, and lines their insides with india-rubber, or other soft material, to isolate the lamp iron from the carriage, or the lamp from the lamp iron. The invention also includes the application of india-rubber to the doors and locks of railway carriages.—Patent completed.

2797 R. ELLIS. *Apparatus for disconnecting conveyances from animals drawing the same.* Dated October 4, 1867.

We cannot here quote the details of this invention.—Patent abandoned.

2798 G. H. D. MATHIAS. *Improvements in the construction of ships and vessels.* Dated October 4, 1867.

The object of this invention is to gain an increase of speed and stability for steam ships by so firmly connecting two sister ships that there cannot be the least fear of their parting at sea. The ships are built as ordinary vessels, only the proportion of the length to the breadth is about double that of ordinary steamers, about fifteen or sixteen to one. These vessels are constructed side by side with a framework in them (about four or five such in each vessel). This framework rises above the deck to some height, and is contrived so as to exactly receive the connecting tubes or girders; four or more tubes of open or lattice girder work are constructed; their length is about three times the width of one of the vessels. These tubes will also support a wooden deck extending over most of the space between the sister ships, and this wooden deck will be made of open grating work, fore and aft, to let any sea that is shipped pass through immediately.—Patent abandoned.

2799 J. H. JOHNSON. *Improvements in machinery or apparatus employed in the manufacture of bread.* (A communication.) Dated October 4, 1867.

This invention consists in the use in braid-making machines of a reciprocating "latch" needle, operating in combination with a vibrating lever, and certain thread guides, so as to produce a braid from a thread carried by the lever; also of a certain plate and spring combined with the above in order to flatten the braid as it leaves the machine. The invention cannot be fully described without reference to the drawings.—Patent completed.

2800 R. HATTERSLEY. *Improvements in mechanism or apparatus for distributing printers' type ready for hand or machine composing.* Dated October 4, 1867.

The object here is to distribute type from the line as set up for printing by operating by hand upon keys, the type being manipulated or acted upon entirely by the mechanism, the operator having simply to distinguish each type as it comes forward, and press a corresponding key to distribute the type into its proper receptacle with great rapidity. The improvements, when used for distributing type ready for use in a composing machine, are combined with a modified form of the machine for classing type, for which letters patent were granted to the present patentee December 17, 1862 (No. 3365), but when used for distributing type into the ordinary printers' type case, only a short length of the channels or grooves leading to the table are used, shoots being substituted, so that the type may slide down inclines by gravity to their own particular case. We cannot here produce the details of the invention.—Patent completed.

2801 J. ANDERSON. *Improvements in obtaining chlorine, sodium, potassium, phosphorus, and their compounds.* Dated October 5, 1867.

This invention has for its object the obtaining of chlorine, sodium, potassium, phosphorus, and their compounds, in an improved and economical manner, and it consists, principally, in the application of a very high temperature to materials containing the substances sought in the presence of other substances required in bringing about the necessary reactions, the requisite high temperature being applied by passing through the materials a gas, such as carbonic oxide, or nitrogen containing no free oxygen.—Patent completed.

2802 W. E. GEDGE. *An improved formation of wrapper or bale cloth specially adapted for packing combed wool.* (A communication.) Dated October 5, 1867.

This wrapper is composed of a strip of cloth having a length of about 11ft. 2in., by a breadth of about 2ft. 11¼in., to which are fitted two strips of the same width, and having each 5ft. 7in. in length. The most suitable dimensions for a wrapper for packing combed wool are those above given. The wool is placed in the centre of the wrapper, and the sides are folded over upon it and sewn together.—Patent abandoned.

2803 G. MARTIN. *Improvements in the treatment of mixed fabrics, and the extraction of wool therefrom, and in the construction of apparatus to be used for such treatment, and for other purposes.* Dated October 5, 1867.

Here, after the usual process of steeping the materials in acid or other chemical, the same are placed within a stove or vessel similar to the ordinary rotary boiler, but of such dimensions as may be necessary to carry the quantity of rags, cotton, or other material to be operated upon, the apparatus being actuated by suitable gearing connected with a source of motive power, as well understood. In order to raise the heat requisite to effect the objects of this invention, the trunnions at either end of the stove or vessel, and upon which it rotates, are made hollow; steam or hot water pipes or flues, charged with heated air, are so arranged as to pass through the trunnions for the purpose of heating the interior of the stove or vessel. The interior of the stove or vessel is provided with spikes, ledges, or other analogous contrivance or contrivances for agitating and separating the rags, cotton, mixed fabrics, or other materials to be operated upon or dried as the vessel rotates, the steam or moisture evolved or given off being carried away by an exhaust pipe which passes through the trunnions, or through suitable openings in the side or ends of the vessel itself.—Patent abandoned.

2804 J. S. WILLIAMSON. *An improved apparatus for drying corn, malt, or other similar substances.* Dated October 5, 1867.

This invention consists in passing corn or other substances upon a screen or screens through an intensely heated chamber, constructed either of iron or brick, whereby the smoke and gases generated by the fire are prevented from coming in contact with them. The screen or screens have perforated bottoms, and have a reciprocating motion imparted to them by a crank or other mechanical contrivance.—Patent abandoned.

Digitized by Google

2805 W. LOW and J. TREADWELL. *Improvements in riveting the soles of boots and shoes.* Dated October 5, 1867.

This invention consists in riveting the soles of boots and shoes in a groove or channel with a particular shaped rivet, in such a manner as to present all the appearance of a sewn boot or shoe, having also greater strength, and requiring fewer rivets.—Patent completed.

2806 A. M. GILLHAM. *An improved steam engine.* Dated October 5, 1867.

The main shaft or arbour is to have a right-hand and left-hand screw, having a suitable nut or nuts or one or more proper steadfasts in lieu thereof, working either therein or thereon; the said nut, nuts, or steadfasts are to be worked backward and forward by a piston with suitable connections, so as, for instance, that, in the one movement of the piston, one nut or steadfast shall be fast in such way as in moving on the shaft the said shaft shall be caused to revolve, and on the reverse movement of the piston the said nut or steadfast shall be released from such fixture, and the second nut or steadfast shall, in such like manner, and in lieu thereof, become fast, and traversing with the reversed movement of the piston in or on the reverse screw of the shaft aforesaid, shall cause the said shaft to revolve in the same direction as at the first.—Patent abandoned.

2807 A. BRADBURN and S. T. MARSH. *Improvements in jointed rules.* Dated October 5, 1867.

This invention consists in providing a means whereby jointed rules, whether single, double, or of more folds, may be fixed and set rigidly to any desired angle, or to form a straight-edge. This is effected, for instance, in the case of a single-jointed rule, by the employment of a slide or bolt working by a slot upon suitable pins or guides, and this slide or bolt is attached upon one of the inner edges of the rule, so as to slide in and out of the jointed position which is suitably recessed at given angles for such purpose, a thumb-piece or other similar means being provided for actuating the slide or bolt. In applying the invention to rules having a number of joints or folds, the patentees can use such number of these slides or bolts as may be requisite.—Patent completed.

2809 L. WILLIAMS. *An improved combined lift and force pump.* (A communication.) Dated October 5, 1867.

The object of this invention is to enable an ordinary pump to throw a constant stream of water with only one foot-valve. To a suitable casting or valve-box containing the foot-valve of the pump, placed immediately over the suction pipe, the inventor connects three barrels, the area of the middle barrel being equal to the combined area of the two outer barrels. The middle barrel is fitted with a ram, and the said barrel is fixed immediately over the foot-valve of the pumps; the other barrels are each fitted with a bucket, and the rods thereof, as also that of the ram, are connected by their upper ends to a cross head, the ends whereof work in guides, and to this said cross head a connecting rod is attached, communicating with any suitable prime mover. The kind of valve he proposes to employ is an equilibrium valve, well known by miners as the Cornish valve. Another important feature in this invention consists in adapting a hinged or sliding door to the valve-box, by which access can be readily had to the valve when necessary. The barrels containing the buckets are connected together by a branch pipe, so as to form one outlet for the flow of water. The ram and buckets move up and down together; the down stroke of the ram forces the water through the buckets, and the up stroke thereof forms a partial vacuum in the barrels, by which they are again filled with water at the same time the buckets are forcing the water out of their respective barrels, and by these means a continuous stream of water may be raised and thrown. Instead of three barrels, two only may be used, one fitted with a ram, and the other with a bucket, the action being precisely the same, viz., to raise and throw a constant stream of water. —Patent abandoned.

2810 J. PIDDINGTON. *Improvements in pneumatic springs, specially applicable to railway rolling stock.* (A communication.) Dated October 5, 1867.

This invention consists in employing the elasticity of air for the construction and arrangement of springs suitable for any kind of industrial requirement, but chiefly for the rolling stock of railways, as buffers, drawing and bearing springs. A cylinder closed at one end, and the inner surface of which is turned so as to be perfectly smooth, is made of such strength as to contain air at any fixed rate of pressure, an air-tight piston being so arranged as to work in the cylinder. If by the force of any weight or sudden shock the piston is driven back into the cylinder, the pressure of the air increases in proportion to the decrease of volume thus produced, and upon the force being entirely or partially removed, the elasticity of the air restores the piston to its original position, or to a position proportionate to the remaining weight or force to be sustained or resisted.—Patent completed.

2811 N. F. TAYLOR. *Improvements in means or apparatus to be used in impregnating air and aeriform fluids or gases with hydrocarbons, and in burners used in burning the inflammable air obtained.* Dated October 5 1867.

Here, upon endless chains or bands having motion given to them by a pair of rollers, and supporting at short intervals apart pieces of perforated flannel, felt, or sponge, or other open work capable of holding hydrocarbon liquid in suspension, is caused to travel a tube, or endless and elongated chamber, in which the pieces of flannel or other open or porous matter act, somewhat as a series of pistons or buckets, to prevent as much as possible the passage of the air or other aeriform fluid to be impregnated except through the porous substance. The hydrocarbon liquid is supplied to the lower part of this tube or endless chamber from a suitable reservoir placed by the side of it through a passage with a valve acted upon by a float into an attached chamber, which chamber communicates with the bottom of the tube or endless chamber by a tube or limb of the endless tube or chamber, up which it is caused to flow to the top, and then down the opposite side or limb thereof, and out at the lower part of such side or limb. The upper part of the endless tube or chamber is in communication with the upper part of the reservoir of the hydrocarbon, so as to equalize the pressure thereof. There is also an air passage from the float chamber to the upper part of the reservoir. The air or aeriform fluid to be impregnated is forced through the apparatus by bellows placed in a chamber where the movable head or heads of the bellows act as a piston or pistons with sliding valve passages operated from a shaft worked by a spring or weight and suitable gear. By these means the atmospheric air surrounds all parts of the endless chamber. —Patent completed.

2812 J. GOODFELLOW. *Improvements in steam engin* Dated October 7, 1867.

This invention consists in improved arrangements for reducing the pressure on the valve and reducing the friction to a minimum. The top of the valve is open, instead of closed, as at present, and on the top there is a plate cast or connected to a piston working in a short cylinder, there being a hole through the plate and piston to allow steam to pass to the top of the said piston to balance the pressure. Or instead of the hole a passage may be made from the steam pipe to the top of the piston. The inventor supplies steam to the valve through the central port generally used as the exhaust, and exhausts the steam through the outer parts generally used as the steam ports. The steam passes through the central port into the interior of the valve, and thence through the hole in the plate and piston to the top of the piston, and as there is nearly the same pressure of steam on the under side of the plate and top of the piston, the valve is released from the pressure of the steam, and enabled to be moved to and fro with a small amount of power and diminished friction, and similar arrangements may also be applied to a cut-off valve.—Patent abandoned.

2813 J. SMITH. *Improvements in machinery or apparatus for moulding metal.* Dated October 7, 1867.

One part of this invention consists in combining and arranging mechanical means for lifting the top moulding box and lowering the bottom moulding box either simultaneously or separately. To produce the desired effect the patentee employs two or more eccentrics fixed on a rotary shaft, and places them in two opposite positions, and connects them by rods or bars to the top and bottom boxes respectively, by the action of which motion will be given to the boxes in opposite directions to each other—Patent completed.

2814 H. FAULDER. *Improvements in machinery or apparatus for washing and cleaning currants and raisins or other similar fruit.* Dated October 7, 1867.

This invention consists of a novel combination of apparatus for washing, rinsing, and drying the said fruit. The washing of the fruit is effected in a vessel, the whole or a sufficient portion of the surface of which is perforated with holes of a suitable size to retain the fruit, and at the same time to allow of the passage of the extraneous matter. The said vessel is, by preference, so shaped as that the fruit can be readily thrown into the same from a scoop or shovel, and when sufficiently washed can be discharged therefrom by tilting or inverting the said vessel, for which purpose it may be hinged to the framing of the apparatus. During the process of washing, the said vessel is partially immersed in a cistern containing water, in which the currants are agitated by stirrers or beaters attached to a shaft which revolves in the vessel, the cleansing of the fruit being assisted by admitting a stream of clean water to the interior of the washing vessel, an overflow passage being provided to maintain the surface of the water in the cistern at a constant and suitable level. —Patent abandoned.

2815 C. J. GALLOWAY. *Improvements in looms for weaving.* Dated October 7, 1867.

This invention has reference to a former patent, dated September 18, 1867 (No. 2624), granted to C. Litster and G. Storey. One of the present improvements consists in employing, in the place of the piston and cylinder, a bellows or collapsible air-tight bag, which may either be actuated in the same manner as the piston in Litster and Storey's arrangement, or, by preference, the bellows or bag is acted upon by a spring of any suitable form, or an elastic cushion inflated or otherwise tending to compress the bellows. At the forward beat of the lathe a rod connected to the bellows comes in contact with and is thrust back by a stop on the loom frame, and thus causes the bellows to be distended. The bellows are held in this position by a catch on the lathe, which is so acted upon by a lever worked by the gearing to the healds of the loom, or by any other suitable part of the mechanism of the loom, that at every alternate backward beat of the lathe the catch is released, and the bellows are compressed by the spring, so as by the blast of air produced to throw the shuttle along the race. Another part of the invention has for its object to form a cushion in the shuttle-box for the shuttle to strike against. Another part of the invention consists in providing the internal surfaces of the shuttle-box with a packing of leather, india-rubber, cloth, or other suitable material of a yielding nature, between which the shuttle fits sufficiently tight to prevent its rebounding from the shuttle-box until it is forced out by the action of the blast.—Patent abandoned.

2816 C. D. ABEL. *A new or improved process and apparatus for refining camphor.* (A communication.) Dated October 7, 1867.

This invention consists in refining camphor by a process of distillation, and by running the same while in a fluid state into moulds, instead of by the process of sublimation heretofore employed, whereby the cost of manufacture is greatly reduced.—Patent abandoned.

2817 R. P. FAUCHEUX. *Improvements in pipes and cigar tubes.* Dated October 7, 1867.

This invention has for its object improvements in pipes and cigar tubes, and relates to the applications of means whereby the nicotine and other condensible noxious vapours given off during smoking are arrested and prevented passing into the mouth of the smoker. For this purpose the patentee forms on or fixes to the stem of the pipe or cigar tube a pointed tube which enters a tube or reservoir placed on the stem of the pipe or cigar tube. He also employs another pointed tube which also enters the tube or reservoir, which may be fixed at the middle, end, or other suitable part of the stem of the pipe or cigar tube. If desired, the tube or reservoir may be supplied with water, and in some cases he forms such reservoir in two parts separated from each other by a portion of the stem of the pipe or cigar tube, each part having one of the pointed tubes entering therein.—Patent completed.

2818 J. A. MAYS. *Improvements in mining and other lamps, and in lamp and candle cases and holders.* Dated October 7, 1867.

Provisional protection has not been granted for this invention.

2819 D. SWAN. *Improvements in the manufacture of zinc.* Dated October 7, 1867.

This invention consists in separating the zinc from the materials operated on, and condensing it in the form of fume, which is collected and afterwards treated by well-known processes to obtain the pure metal. For this purpose, a cupola blast furnace, or other convenient furnace, is employed, and into it the ores or materials are introduced with such a quantity of coke or other carbonaceous matter as is sufficient to bring the entire mass to the heat that will reduce and volatilize the zinc, when the impurities will sink to the bottom of the furnaces, whence they can be withdrawn from time to time. In order to collect the zinc fume the furnace is provided with a flue leading into a series of chambers of sufficient capacity to allow the whole of the vapours to condense, and the zinc is collected in these chambers and is removed thence to be treated in the ordinary way.—Patent abandoned.

2820 H. TROTTER. *Improvements in the manufacture and packing of fire-lighters and artificial fuel.* Dated October 7, 1867.

Here turf is first cut into sods from the bog in the ordinary way, and then weathered and dried in the usual manner. The sods are then taken into a hot room and thoroughly dried, after which they are taken to a sawmill and cut into pieces of suitable form and size, according to the purpose for which they are intended. These thoroughly dried pieces of turf are then either dipped into a thick solution of clay and water first, and, when dried, immersed in cold coal tar oil alone, or they are immersed in a sufficient quantity of cold coal tar oil mixed with clay, which latter regulates in either case the infusion of the oil into the turf, which retains its solidity and requires no further labour or expense in drying out the surplus oil with which the turf is overcharged, as is the case when the turf is saturated with oil alone, and it also leaves a coating of clay which fills up the pores of the turf and prepares it for the next process. The pieces of turf thus prepared are now dipped into hot resin, which is mixed and tempered with tar oil or mineral shale grease or oil (about 1lb. to 2lb. of resin) to make the resin together, and not so liable to break, and also to cause it to flow and spread over a larger surface by being more liquid. The dipped pieces of turf are then thrown into sawdust from the turf, which may be mixed with a little ground cannel or other coal to increase the heating properties, and are afterwards packed into pasteboard, strawboard, wooden or tin canisters, or other vessels or parcels capable of obtaining the same, with a sufficient quantity of sawdust, ground turf, or other cheap dust or like material to cover them well over when packed, the packing material being in most cases consumed with the fire lighter or fuel.—Patent abandoned.

2821 T. OLLIS. *Improvements in registering apparatus applicable to omnibus and other vehicles.* Dated October 7 1867.

This invention consists in the application of apparatus similar to that used for stamping or endorsing purposes, for registering or indicating the number of passengers that have travelled by an omnibus or other vehicle. We cannot here give space to the details of the invention.—Patent completed.

2822 J. H. BROWN. *Improvements in utilizing refuse animal matters, and producing skins and sheets therefrom.* Dated October 7, 1867.

This invention has for its object the production of skins or sheets for the purposes of writing, drawing, tracing, bookbinding, box and case covering, and other purposes for which vellum, parchment, cotton, cloth, and the various sorts of leather are employed. For these purposes the inventor takes the refuse skins, or parts of skins, fleshings, roundings, tendons, and all other suitable animal matters possessing a fibral character, and having cleansed them of all dirt and impurities by submitting them to a caustic bath composed of quick lime and alkali and water, in which they are to remain until they are quite soft and flexible; they are then removed, and by means of a rotary knife, or other suitable machinery, are cut into slivers, and beaten into a plastic mass. In this condition he adds sulphurous, sulphuric, hydrochloric, nitric, acetic, or other suitable acids, in the proportion of 1 or 2 per cent. of the water required to bring the mass into a partly fluid state. It now undergoes a thorough disintegration by beating in a rag engine used by paper makers, until it assumes the character of what is called by paper makers "half stuff." It is now submitted to the bleaching process in the same manner as rags are, and freed from the lime and acid obtained during the bleaching process by means of washing and the usual processes, as employed in the production of paper from rags. It is probable that a petition will be lodged for an extension of time for completing this patent, but at present it is in that stage which we designate as—Patent abandoned.

2823 R. GARRATT. *An improvement in ball and other cocks* Dated October 8, 1867.

This consists of an improvement in the construction of ball and other water cocks, which is particularly applicable where the supply is at a high pressure. The end of the supply pipe is turned upwards, and in it is mounted a central spindle capable of sliding up and down. On this spindle is fixed an inverted cup of lead or other metal, inside which is a disc of india-rubber, forming a water-tight valve, which, when the spindle is pressed down, effectually closes the orifice of the supply pipe and shuts off the flow of water. The body of the cock which encloses this valve may be of a globular or other convenient form, having an opening below for the escape of the water, and another at the top through which the upper part of the valve spindle works. This valve spindle is connected to the ordinary lever and ball when a self-acting arrangement is required, and if otherwise the spindle is provided with a screw thread working in a screw formed in the opening through which it passes out, and the valve is opened or closed by turning the spindle round by means of a key or otherwise.—Patent abandoned.

2824 E. BENINGFIELD. *An improved lifting machine, applicable as a fire-escape and for repairing and decorating houses and other buildings.* Dated October 8, 1867.

Here the inventor takes three pieces of light metal tubing, or tough light wood, from about 20ft. to 30ft. long, more or less, and hinges or otherwise connects each piece about midway of its entire length, so as to be capable of doubling up when out of use, and of forming three entire long legs when undoubled for use, forming, in fact, three long legs as a tripod stand.—Patent abandoned.

2825 J. DEAN and T. TURTON. *An improved apparatus for the prevention or consumption of smoke.* Dated October 8, 1867.

This invention consists in an arrangement of serpentine

Digitized by Google

flues, whereby the smoke and other unconsumed products of combustion are prevented from passing away directly to the chimney until the whole has been consumed, and not only is smoke thus prevented, but a great economy fuel is also effected, as little or no waste heat from the fuel passes away uselessly up the chimney.—Patent abandoned.

2826 J. B. HULME. *An improved apparatus to be used in excavating.* Dated October 8, 1867.

This invention relates to an improved apparatus for "getting" the earth to be excavated. The patentee employs a pick, which, instead of being worked by hand, is fixed on a shaft driven by a small engine, and he prefers to give the pick a continuous revolving motion, which may be done by the ordinary crank motion. The engine and pick are mounted on a suitable frame, which is supported in such a manner that it may easily be raised or lowered or moved from side to side, as may be required, and so that it may be turned round to enable the pick to work in different directions.—Patent completed.

2827 J., S. A., G. E., and F. F. READING. *A new or improved mode of securing or uniting stay, corset, or legging busks.* Dated October 8, 1867.

This invention applies to the description of busks composed of two strips, usually of steel, and connected together, wholly, or partly, by means of hooks and studs, and consists in the addition of a spring bolt sliding in a case which locks the shank of one of the studs within the seat of the hook, which prevents the stud so locked from disengaging until the bolt is withdrawn from the hook sufficient to allow the stud shank to pass.—Patent abandoned.

2828 A. TICOZZI. *An improved preparation or lotion for diseases of the eyes.* Dated October 8, 1867.

To 1 quart of water the inventor adds ½oz. of extract of onions, ½oz. of powdered sugar, ½oz. of sulphate of zinc, and 1oz. of white copperas, which contains magnesia, cream of tartar, and arsenic. When all the ingredients are dissolved in the water, the liquor must be filtered, and then it will be fit for use.—Patent abandoned.

2829 R. BEARD. *Improvements in stoppers for bottles, jars and other vessels.* Dated October 8, 1867.

One part of this invention relates to the rendering wood stoppers, such as are described in the specification of a patent granted to N. Thompson, dated January 1, 1866 (No. 3), or others of similar construction, impervious to air and water, and causing such stoppers to fit or pack more closely to the neck of the bottle. This is accomplished by coating the outer surface of the stopper with a composition which can be rendered sufficiently hard to drive well into the bottle, and to extract cleanly from the same, and yet possessing sufficient pliability to form a tight packing into the neck of the bottle by giving or yielding to any inequalities therein. This composition by closing or hermetically covering the pores of the wood on the outer side prevents the escape of air or gas from the bottle, or the oozing of any fluid; still the wood not being impregnated thereby is left in its natural state, and will swell or expand in the bottle, and the composition also possessing sufficient elasticity to expand with it. By preference the inventor uses a composition of drying oil (well boiled), and resins, into which he mixes cotton or other fibre and pigment to give any desired colour and assist in giving the desired solidity; or a composition of resins, fibre, and pigment without the oil may be used. Vulcanite or ebonite composition may also be employed.—Patent abandoned.

2830 F. LOVE, W. ARMSTRONG, and L. WIDDOWSON. *Improvements in apparatus for boring holes in stone, shale, and minerals.* Dated October 8, 1867.

Here the inventors employ a drill or auger carried at one end of a long screw; the screw works through a nut or nuts on disc plates, or other support, carried by a post capable of being lengthened or shortened, so that it may be fixed between the floor and roof of a mine, or between its sides. At the opposite end of the screw is a crank handle or pulley or wheel by which rotary motion may be given to the screw, or the screw may be otherwise driven a forward motion is thus imparted to the drill or auger at the same time that it receives a revolving motion. The stem of the drill is twisted, or of a spiral form, so that the pieces cut away are by it discharged at the mouth of the hole that is being bored. The nut or nuts or other supports through which the screw works can be raised or lowered on the post so that the drill can be set to work at any desired height, and the nut or nuts (or disc plate or other support) are also so mounted as to be capable of turning on an axis at right angles to the length of the post; the drills can thus be set at any desired angle to the face of the rock or work.—Patent abandoned.

2831 J. B. BROWN. *Improvements in railway carriage and other lamps.* Dated October 8, 1867.

In constructing railway carriage lamps suitable for burning petroleum and other oils the inventor encloses the burner in a glass bowl, as heretofore, but, according to this invention, he makes this also the reservoir for the oil which is contained in the lower part of it, protected by a cover or diaphragm of glass inserted into the bowl, so as to rest upon a flange within it, or it might be otherwise supported. In the centre of this cover or diaphragm is an opening to which a petroleum oil burner is fitted, and the wick dips down into the oil. The burner carries a glass chimney which surrounds the flame. Air is supplied to the glass bowl by perforations through it a short distance above the glass cover or diaphragm. A flange at the top of the bowl is set into the end of a metal drum which enters and fits the aperture in the roof of the carriage, and over this there is a cylindrical hood perforated with small holes to check any sudden current of air past the chimney of the lamp. Down the sides of the drum air passages are formed which aid in supplying air to the bowl. Within the metal drum a reflector is placed to throw down the light from the flame; it also serves to enclose the bowl at the top. The chimney passes through the centre of the reflector, and its upper end is enclosed in a casing of wire gauze, which the reflector carries, and which is intended to check any blast of air descending the chimney or otherwise.—Patent abandoned.

2832 J. PLAYER. *Improvements in the manufacture and refining of iron and steel.* Dated October 8, 1867.

This invention consists in the refining, dephosphorizing, and desulphurizing crude pig iron by mixing it in a furnace, cupola, or refinery (in addition to the coke or other fuel by which it is melted and suitable fluxes) with ores or minerals containing a large percentage of titanium, manganese, or copper mixed with iron; for instance, as minerals found in Norway, New Zealand, and elsewhere, and sold and known as titanic iron ore, ilmenite, and by other names.—Patent abandoned.

2833 E. G. WOLFFGANG. *Improvements in the manufacture of ribbons.* (A communication.) Dated October 8, 1867.

This invention has for its object the manufacture of ribbons of cotton velvet with silk, satin edges, or stripes, and consists in the mode described of preparing the velvet to receive strips of silk satin as required, and of applying such strips to the same. For this purpose the face of the velvet is indented in stripes of the requisite width, and at the requisite distances apart, by passing it through a pair of rollers, the lower one of which is smooth, and the upper one has ribs or projections formed on it, corresponding with the required widths and positions of the stripes. The silk satin out of which the strips are intended to be formed is covered on the back with a thin coating of caoutchouc, or other suitable adhesive substance, and then divided into strips of the required width by its being passed between two suitably formed steel cylindrical cutters. The strips are applied to the velvet by the pressure of suitably formed rollers, which are heated, and by means of their heat dissolve the caoutchouc or adhesive substance, thereby causing the strips to adhere firmly to the velvet as required.—Patent abandoned.

2834 R. REID and E. H. CRAIGIE. *Improvements in mattresses, sofas, couches, ottomans, easy chairs, railway carriage seats, and other such like or similar articles.* Dated October 8, 1867.

This invention is not described apart from the drawings.—Patent completed.

2836 J. BARKER. *Certain improvements in the method of consuming smoke, and in apparatus connected therewith.* Dated October 9, 1867.

This invention consists in the application of jets or flames of gas, or other equivalent, to ignite the gas which is abundantly contained in the smoke after it has passed along the flue, and is passing to the chimney, for which purpose the inventor applies one or more gas supply pipes in the space behind the flue (or in the flues, if desired), and provides burners in such pipes in such a position that the draught from the furnace will not extinguish them, which is accomplished by placing them in the opposite side of the pipe to the draught, so that the back part of the pipe protects the gas flames. When gas is admitted to these tubes and ignited, such gas flames are surrounded by the gas and smoke from the furnace, and the said gas becomes ignited by the jets, and the combustion extends and is maintained the whole length of the flue, which also consumes the carbon in the smoke.—Patent abandoned.

2837 J. H. JOHNSON. *Improvements in projectiles.* (A communication.) Dated October 9, 1867.

This invention relates to the manufacture of shells, and other self-exploding projectiles, and consists, essentially, in so constructing such projectiles that the necessity for caps or priming is obviated, and, consequently, greater simplicity and economy of construction are obtained. The invention cannot be described without reference to the drawings.—Patent completed.

2838 H. WALLWORK. *Improvements in machinery for the manufacture of hats.* Dated October 9, 1867.

One part of this invention relates to machinery for "curling" or shaping the brims of hats, that is, shaping and turning up the edge of the brims, and the invention consists in improved arrangements and combinations of mechanism for the purpose. The hat, previously to being shaped or "curled," must have its brim softened by heat, and the improvements in arrangements for this purpose consist in applying the heat so that it will only act upon the brim, and not also upon the body of the hat, as hitherto. The patentee accomplishes this part of the invention by making the heating chest or bed with holes through it opposite the body of the hat, so that the brim only of the hat comes over the heated surface, and also by causing a current of cold air to circulate within or over the body of the hat to keep it cool, such current being produced by a fan or other means. A similar heating chest to that above described is used for giving the finish to the "curl" when the brim of the hat is "bound."—Patent completed.

2839 J. JAMES and T. JONES. *Improvements in the manufacture of rails, bars, and other articles of iron, and in the apparatus employed therefor.* Dated October 9, 1867.

This invention is not described apart from the drawings.—Patent completed.

2840 W. POTTS. *Improvements in gaseliers.* Dated October 9, 1867.

The patentee claims the combination of a hollow screw and stuffing box, and the parts connected therewith, substantially as described and illustrated, whereby, on the rotation of the said screw, the movable part of the gaselier is raised and lowered without the arms and body of the lamp moving round with the screw.—Patent completed.

2841 J. SPEIGHT. *Improvements in machinery or apparatus for spinning, twisting, and roving worsted or other fibrous substances to facilitate the doffing.* Dated October 9, 1867.

This invention relates to that class of machinery or apparatus for spinning, twisting, or roving, known as throstle frames and cap frames, and the improvements consist in the employment of duplicate spindles or bobbin studs, that is, in having two sets of spindles or studs so arranged that, while one set is in position for spinning, twisting, and roving, the other set is in position for doffing. Each set, according to one method, is mounted on a shaft capable of turning on its axis, and also of sliding endwise, such shafts being placed and operated so that each set of spindles or studs may change position alternately, or as and when required.—Patent completed.

2842 R. SMITH. *Improvements in mounting and driving millstones.* Dated October 9, 1867.

The patentee claims fixing one of the mill stones on a rotating vertical axis, whilst the other stone is hung upon a universal joint or gimbals contained in the eye or opening in the centre of the stone. He also claims the combining with stones so mounted and driven a set screw or screws to control the stone hung on the universal joint or gimbals.—Patent completed.

2843 E. G. P. THOMAS. *Improvements in dyeing black and grey, and in preparing materials therefor.* (A communication.) Dated October 9, 1867.

At the present time there are well-known processes by which an aniline black colour may be printed upon cotton, but there is no known process by which either wool or cotton can be successfully dyed with aniline black. These results may, however, be attained by the following processes. To dye wool—The wool is first mordanted by maintaining it for about an hour in a boiling bath composed in the following manner:—Water, 1 litre; bichromate of potash, 10 grammes; sulphate of copper, 6 grammes; sulphuric acid, 1 gramme. The wool is then washed and introduced into a bath of oxalate of aniline containing a slight excess of oxalic acid. This bath, which should contain about 40 grammes of oxalate per litre of water, will enable the dyer to obtain in a few moments a most intense black. The wool should not be dipped into the bath until the latter has acquired a temperature of about 40deg. Centigrade. The heat must then be continued, but it should not be raised to the boiling point.—Patent abandoned.

2844 T. NELSON. *Improvements in preparing the surfaces of paper or other material for drawing purposes, and in the application of the same to lithographic and other kinds of printing.* Dated October 9, 1867.

Here the patentee employs a plate or cylinder of metal or other material, or a sheet of film of any substance or material with a minute granulated or lined pattern on the surface for impressing the paper or other material. The paper or other material so impressed is then ready for ordinary drawing purposes. The following is the manner in which the patentee usually operates:—He takes a sheet of copper or other metal, and he grains the surface (it may be by the aqua tint process, or by the use of a graver by hand, or by a ruling machine and he lays a sheet of paper on the plate so prepared, and passes it, together with the plate, between calendering or hot-pressing rollers.—Patent completed.

2845 W. WARREN. *Improvements in the arrangement and construction of street sweeping and cleaning machines.* Dated October 9, 1867.

This invention relates to improvements in the arrangement and construction of machines for sweeping and cleaning streets of the character described in the specification of a patent granted to J. Whitworth, dated August 2, 1842 (No. 9435), and one part of these improvements consists in constructing the axle driving the endless chain of brushes in two parts socketed together, or otherwise arranged so as to render their action independent of each other, which arrangement enables the patentee to apply driving gear to each of the supporting and travelling wheels of the cart, so as to give motion to endless chains of brushes or cleaning instruments carried by axes, the parts of which are also arranged to act independently. The endless chains and brushes are also arranged in separate sections, so as to work separately, or in combination. By this arrangement of the driving gear the power is equally applied (in giving motion to the sweeping and cleaning apparatus) in place of actuating it from one side only of the machine, as heretofore practised. By this arrangement of the driving gear the width of the cleaning apparatus may be greatly increased without increasing the draught power required to draw the machines.—Patent completed.

2846 C. AVERY. *Increasing the celerity and safety of loading guns and pistols at the breech, and of discharging the same.* Dated October 10, 1867.

This invention relates to firearms wherein the breech is closed by a block pivoted at its rear end to the sides of the breech chamber, which has an aperture in the top, the forward end of the block being turned upward through this aperture when the breech is opened. The improvements consist, chiefly, in the novel arrangement of the breech block, and in the peculiar construction and combination of the devices for operating the said block to open and close the breech, and for securing the same when the breech is closed; also in the peculiar arrangement of the trigger and main spring, in the devices employed in connection with the same, and the firing pin; and in the means for preventing the accidental discharge of the piece before the breech is properly closed. The said improvements also consist in the novel mode of fixing and adjusting the bayonet. The breech block is made to slide back away from the end of the barrel, and to turn upward upon its pivot to allow the cartridge to be inserted into the charge chamber, which is formed in the said block; the latter is operated by a hinged piece which is fitted below the breech chamber, and is forced down when released by its locking bolt by the main spring, which is a flat piece of steel bent into the proper form, and lying in a recess in the breech shoe. The locking bolt is drawn back by a lever and forced into its recess by a spiral spring. When the breech is closed, the block is kept solidly in place by a projection on the hinged piece which lies in the breech chamber behind the said block, and is connected thereto by a link or swivel; the firing pin is arranged to penetrate the under side of the charge chamber, and is driven into contact with the cartridge by a hammer which is pivoted to the hinged piece. This hammer is held when the arm is cocked by the trigger, which is arranged in line with the hammer and bolt lever, the said hammer, lever, and trigger being protected by a trigger guard of suitable form attached to the hinged piece. The bayonet is attached to a ring or ferrule, and is fitted to slide in a groove at the under side of the barrel, and when pushed forward is held by a spring catch.—Patent completed.

2847 R. BROTHERTON and J. MALDRON. *Improvements in the manufacture of lamp-posts.* Dated October 10, 1867.

The patentees claim making the principal post of the lamp, and the crossbar of the said post, of wrought-iron tubing, and fixing the crossbar, lamp-iron, and cast-iron or wrought-iron skeleton frame to the said post, substantially as described and illustrated.—Patent completed.

2848 T. BLACKHURST. *A new or improved composition to be used to prevent the oxidation of iron, the fouling of ships' bottoms, and other submerged things, and preserving wood from decay and from worms, and also preserving iron and wood exposed to the action of the atmosphere.* Dated October 10, 1867.

This composition is made of pitch and crude naphtha or light oil, the said pitch being the residuum after distillation of coal gas tar. The crude naphtha or light oil is the first runnings from the still in the process of distillation of coal gas tar, the specific gravity of which is, usually, about 900 deg., water being 1,000deg. The patentee mixes these ingredients together in very nearly the following proportions—namely, pitch, 1lb., crude naphtha or light oil, 4oz. to 6oz.; he then puts these ingredients into a vessel, taking care to stir them occasionally until the pitch is dissolved, or has arrived at the consistency of paint.—Patent completed.

Digitized by Google

2849 A. F. HOBHOUSE. *Improvements in apparatus for propelling vessels.* (A communication.) Dated October 10, 1867.

This apparatus consists, chiefly, of a chamber intended to be immersed in water, alternately contracting and expanding, or closing and opening, and by its contraction or closing expelling the water contained within it in the direction required, and also thereby propelling the vessel to which it is attached.—Patent completed.

2850 W. R. LAKE. *An improved device for bunging barrels or casks.* (A communication.) Dated October 10, 1867.

Here the patentee employs a metallic bushing which is to be both screwed into the stave and riveted into the same. The bung is then screwed into the bushing, and a cap plate screwed down over it, so as to thoroughly protect it during transportation. An air channel is cut in one side of the bung for the purpose of admitting air to the interior of the cask for vent when the bung is but slightly withdrawn.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated January 14, 1868.

124 A. Cowling and W. Turner, Eccleshall-road, Sheffield, brass turners. An improvement in the construction or ornamentation of tape measure cases.

Dated February 18, 1868.

176 E. Dorsett, London-street, City. Improvements in the utilization of coal tar and the products arising from the distillation thereof, and in the apparatus employed therein.

Dated January 29, 1868.

306 R. Wilson, Manchester, ironmonger. Improvements in the method of, or means for, forming connections or joints to pipes and other articles for conveying fluids and liquids.

Dated February 24, 1868.

612 R. Nicolls, Aldermanbury, City, fancy trimming manufacturer. A new or improved combined material or fabric to be applied to the manufacture of bags, reticules, writing cases, wristbands, cuffs, collars, belts, and various other articles.

Dated February 26, 1868.

644 E. R. Walker, Fenton, Stoke-upon-Trent, Staffordshire, engineer. Improvements in transmitting motive power to potters' machinery.

Dated March 5, 1867.

766 J. B. Fell, Sparke Bridge, near Newton-in-Cartmel, Lancashire, engineer. Improvements in, or applicable to, locomotive engines, carriages, and permanent way.

768 H. Conybeare, Duke-street, Westminster. Improvements in the manufacture of rails for railways.

Dated March 17, 1868.

910 W. E. Newton, Chancery-lane. Improvements in the process of preparing iron ore for smelting, and in furnaces therefor. (A communication.)

Dated March 19, 1868.

936 J. E. Lane, Great Berkhampstead, Hertfordshire. Improvements in apparatus for heating or warming buildings or apartments, and for other similar purposes.

Dated March 20, 1868.

946 J. G. Tatters, W. Keeble, and B. Newberry, Plymouth, Devonshire. Improvements in the preparation of cigars and mode of lighting the same.

Dated March 21, 1868.

968 R. G. Greenhow, Llanidloes, Montgomeryshire. Improvements in breech-loading firearms and cartridges.

Dated March 30, 1868.

1082 A. B. Walker, Warrington, Lancashire, brewer. Improvements in the application of hot blast or heated air for evaporating salt, brine, and other liquids, sugar, or chemicals, also for heating gas and oil retorts, raising steam in boilers, boiling worts in breweries and distilleries, which improvements are also applicable for bleaching, tanning, and baking, likewise improvements in apparatus used in some of the aforesaid applications.

1085 J. Jordan, Liverpool, engineer. Improvements in the construction of firebars for furnaces.

Dated March 31, 1868.

1086 W. Austin, Greville-street, Hatton-garden, Middlesex, match and box manufacturer. Improvements in the composition, boxes, and surfaces for obtaining instantaneous light from chemically prepared matches intended to be ignited by friction.

1087 F. Taylor, Carey-street, Chancery-lane. Improvements in the fittings of railway carriages.

1089 J. Sinclair, Stirling, North Britain, engineer. Improvements in screw propellers.

1091 H. B. Woodcock, Low Moor, Yorkshire, forge manager. A new manufacture of metal for axles, shafts, rails, tyres, and other purposes.

1093 L. F. P. Riviere, Mark-lane, Middlesex, merchant. An improved velocipede.

1094 J. H. Weston, Kennington-road, Surrey, gas engineer. Improvements in the means or apparatus for lighting and ventilating the interior of buildings, combining a decorative effect.

1095 H. Bessemer, Queen-street-place, Cannon-street, City. Improvements in the manufacture of malleable iron and steel, in the heating and melting of metals, and in the machinery or apparatus employed for such purposes.

1096 J. H. Johnson, Lincoln's Inn-fields. Improvements in sewing machines. (A communication.)

Dated April 1, 1868.

1097 T. Coulдrey, jun., Kirkdale, Lancashire. Improvements in pumps for ships and other purposes, and in the construction of buckets or valves for the same.

1099 A. Scatchard, Cambridge-road, Mile End. Improvements in the apparatus used in the manufacture of aerated bread.

1101 W. A. W. Sleigh, Bayswater, Middlesex, and A. Pye, widow, Howard-street, Strand. An improved appliance for protecting trousers from mud. (A communication.)

1102 W. Smith, Glasgow. Improvements in the manufacture of pig iron.

1104 G. Davies, Serle-street, Lincoln's Inn. Improvements in the construction of centrifugal ventilators or fans. (A communication.)

1105 J. Norris and T. Quarm, Great Russell-street, Bloomsbury, engineers. Improvements in cooking apparatus.

1106 J. Walker and J. Candlin, Wolverhampton, machinists. Improvements in flooring sash and bench cramps.

1107 G. Kynoch, percussion cap manufacturer, and W. Whitehill, manager, Birmingham. Improvements in cartridges.

1109 R. J. Morison, Great St. Helen's, Bishopgate-street, City, merchant. Improvements in cotton gins. (A communication.)

Dated April 2, 1868.

1113 E. Leahy, Cardington-street, Euston-square, London. An improved movable railway for ordinary carriages.

1114 T. Baker, Buckingham Villas, Stratford, Essex. Improvements in umbrellas, sunshades, and parasols.

1116 H. Lafone, merchant, and J. Nicholas, oil refiner, Liverpool. Improvements in the mode of, and means or furnaces for, burning petroleum and other like liquids.

Dated April 3, 1868.

1122 A. De Metz, Wolverhampton, manufacturer. Improvements in commodes or vessels to be used as water-closets, expectorating utensils, or for other purposes.

1124 C. D. Abel, Southampton-buildings, Chancery-lane. A new or improved process and apparatus for refining camphor. (A communication.)

1126 J. M'Culloch, Shawlands, Renfrewshire. Improvements in utilizing old or waste tarpaulin in the manufacture of grease and other useful products, and in apparatus therefor.

1130 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of cast steel and malleable iron from cast iron, and in the apparatus or means employed therein. (A communication.)

1132 G. Piggott, Birmingham, manufacturer. Improvements in electric telegraphs.

1134 J. G. Tongue, Southampton-buildings, Chancery-lane. Improvements in lamps or apparatus for lighting or illuminating purposes. (A communication.)

Dated April 4, 1868.

1136 H. C. Butcher, Wellington-street, Strand. An improved tobacco pipe.

1140 T. Faucheux, Caversham-road, Middlesex, engineer. Improvements in the construction of axles of the wheels of railway rolling stock and other vehicles and other axles and driving shafts.

1142 F. A. E. G. de Massas, Hoxton, Middlesex. Improvements in machinery for cleaning cotton seeds.

1144 R. Nabbs, Peckwater-street, Kentish Town-road. Improvements in locks and latches.

1146 G. Davies, Serle-street, Lincoln's Inn. Improvements in apparatus for washing and separating ores and other materials. (A communication.)

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated April 11, 1868.

1212 S. W. Huntington, Augusta, Kennebec, State or Maine, U.S. A new and useful mode of preparing of veneering paper, cloth, leather, &c.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," April 21, 1868.

3477 F. Roper. Apparatus for driving straw elevators.
3485 O. Barrett and H. Leggott. Knife cleaner.
3506 W. H. Barlow. Apparatus for measuring approximately the quantities of earth work in continuous cuttings or banks.
3508 W. B. Leachman. Rotary water engine.
3512 G. Holcroft and W. N. Dack. Steam engines.
3514 W. J. Fraser. Tubular steam boilers.
3519 J. M. Napier. Appliances for serving mustard.
3522 T. A. Weston. Saws. (A communication.)
3527 J. Ward. Lamps.
3532 W. G. Hanning, G. B. Knott, and L. C. F. Clerc. Lamps. (Partly a communication.)
3534 P. Bawden. Machinery for the manufacture of bricks.
3535 E. R. Sintzenich. Treating paper.
3540 J. Robinson. Manufacture of mohair fabrics.
3542 E. R. Sintzenich. Treatment of gutta-percha. (A communication.)
3546 J. Williams. Abacus for imparting instruction in arithmetic.
3549 A. Bullough. Looms for weaving.
3550 J. G. Settle. Door bolts.
3551 T. Pebardy. Surgical appendages.
3554 H. Atkinson. Gas retort ovens. (A communication.)
3558 W. and F. Bates. Washing machines.
3567 E. and A. Tatham. Manufacture of sinkers for hosiery.
3581 W. Huskisson. Manufacture of bicarbonate of potash.
3584 A. Shrimpton. Papering needles
3585 W. Simons and A. Carmichael. Moulding.
3612 A. Cochran. Machinery for finishing woven fabrics.
3628 E. Lord. Reducing the friction of revolving surfaces.
3657 A. M. Clark. Colouring matter. (A communication.)
3667 G. J. and T. C. Hinde. Manufacture of iron and steel.
3704 A. M. Clark. Permanent way of railways. (A communication.)
3719 J. H. Johnson. Machinery for spinning cotton. (A communication.)
3720 A. M. Clark. Road-sweeping machines. (A communication.)
200 J. H. Johnson. Ships for containing and transporting oils. (A communication.)
215 J. H. Johnson. Furnaces. (A communication.)
740 E. Clifton. Adjustable door handles.
913 J. M. Ure. Apparatus for lifting the driving wheels of a locomotive off the rails.
990 W. E. Gedge. Smoke-consuming fireplace. (A communication.)
1037 W. Manwaring. Reaping machines.
1042 J. Lyall. Looms for weaving.
1057 H. Jones and W. F. De La Rue. Whist counters.
1075 B. Mitford. Apparatus for communicating with deaf and dumb persons.
1078 J. H. Johnson. Manufacture of cast steel. (A communication.)
1085 J. Jordan. Firebars.
1130 J. H. Johnson. Manufacture of cast steel. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed April 15, 1868.

2892	M. Vogl and H. Van Dyk	2939	M. J. Matthews
		2941	W. R. Lake
2894	T. H. Baker and T. Woodroffe	2943	L. Newton and J. Swailes
2895	M. Samuelson	2952	W. Crossley and T. C. Hutchinson
2896	W. R. Lake	2969	W. Beale
2905	D. Pidgeon and W. Manwaring	3054	J. Maddocks
2908	M. Wilkin and J. Clark	3067	O. C. Evans
		3069	W. R. Lake
2914	L. Hamel	3072	A. Chaplin
2916	T. Bell and J. Richardson	3126	R. Leake and J. Beckett
2918	J. Bannehr	3180	C. B. Hodgetts
2920	W. Tredgold and J. M'Neil	3222	J. Morrison
		3285	T. H. Tilley
2922	F. Prudencio, F. Cooper and J. F. Cotterell	3341	E. Townshend
		3570	W. Conisbee
		3685	J. Goodfellow
2925	E. Casper	397	J. A. Jones
2931	H. J. Bale	616	W. R. Lake
2934	J. King	647	A. V. Newton

Sealed April 17, 1868.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, MAY 1, 1868.

COOKING FOR THE ARMY.

BEYOND a doubt the physical condition of an army is almost wholly dependant upon the character of the food supplied to it, and the manner in which it is prepared. This important point was greatly neglected until Captain Grant, some years since, effected a reformation by introducing some radical improvements in the messing of soldiers. The matter has gone on improving up to the present time, when we find Captain Warren taking the question up, and bringing it to a very successful and practical issue. This officer has turned his attention to the better and more economical cooking of food for some time past, and he has succeeded in perfecting an apparatus which answers admirably in every respect. This apparatus formed the subject of a paper by Captain Warren, which was read at the Royal United Service Institution on Friday last. The apparatus consists, primarily, of a stand or plinth, about 8in. high, upon which the body, containing the oven, furnace, and two boilers, are placed. The apparatus thus fitted stands about 4ft. high by 2ft. square on the top. At each side is a tray supported by arms, and which can be closed up when the apparatus is not in use. When in use a tin meat steamer is placed on one and a potato cooker on the other of these trays, the tops of the steamers being level with the top of the oven. Over the potato steamer is another with a perforated bottom for the same purpose, whilst over the oven are two cookers for meat and soup, and over the meat cooker first referred to is another steamer, with a perforated bottom, for puddings or potatoes. Thus put together the apparatus is of T-shape in elevation. Steam is supplied to the steamers from the boiler by pipes through the sides and top of the body of the stove. The boiler is supplied with water through pipes at the back, which are fitted with steam whistles, and give warning directly the water is low. The fire is lighted with a little wood and coal, and with a good draught steam is got up in thirty minutes. The fire is never replenished with more than 2lb. of coal at a time, and the total consumption of fuel (sea coal) should not exceed 25lb. of coal per day per company of 100 men, for breakfast, dinner, and tea.

Captain Warren's apparatus, as now made with an enlarged oven, is calculated to cook for 120 men, or two companies. One of these was in operation in the servants' hall of the Institution during the lecture, and in it was cooked soup, fowl, joints, puddings, and potatoes, all of which were done to perfection. The following statement shows how rations for 120 men can be prepared, each mess being kept separate:—

Company A, consisting (say) of 60 men, in	3 messes
Company B, consisting (say) of 60 men, in	3 ,,
Total . . .	6 messes

	Men.
1st mess. A full bake, or roast in oven, consisting of joint and potatoes under	20
2nd mess. One meat pie in oven, or a second joint and potatoes	20
3rd mess. Meat and soup in top cooker	20
4th mess. Stew	20
5th mess. Warrenized meat in right-hand cooker. (This is cooked in hot air without water) .	20
6th mess. Ten meat puddings in top right-hand cooker . . .	20
Total . . .	120

In addition, 120lb. potatoes are cooked simultaneously in the potato steamer. A dish, termed a sea-pie, consisting of meat and paste in layers, can also be prepared in the top cookers. The total consumption of fuel for the day for 120 men is found to average under 28lb. As regards the economy of this apparatus, it is to be observed that in the early trials of the apparatus at Aldershot, the economy in fuel showed a reduction of fifty per cent. over the steel boilers and ovens. This, Captain Warren states, would have been far exceeded had not the company system been adopted, as the larger the numbers cooked for, the greater the reduction in the consumption of fuel.

Besides the saving by fuel in this apparatus, a reduction in the waste of meat is effected by the process now termed "Warrenizing." This point—as well as that of economy of fuel—was investigated by a committee by direction of the Horse Guards, and they arrived at the most satisfactory conclusions. The points to which they directed their attention were—The time of cooking; the quantity of fuel used; the quality of the food when cooked; and, the general adaptability for use by soldiers. In the first experiment, the meals of an entire company of forty-seven men were cooked in Warren's apparatus and in the usual Deane's boilers and ovens. The result was that coffee for breakfast was prepared in Captain Warren's apparatus in 45min., but in Deane's boiler the time was only 20min. The dinners, however, were the test, and here three messes, one of soup, one of stew and potatoes, and one of baked meat and potatoes, were prepared in Warren's apparatus in 3hrs. 35min., whilst in Deane's the time was 3hrs. 45min. The teas were prepared in each apparatus in 1hr. 45min.; the total time, therefore, was—Warren, 6hrs. 5min.; Deane, 5hrs. 50min.; the latter having the advantage in point of time. This, however, is not so material to the issue, because a certain weight and quantity of food cannot be properly cooked under a certain time, which must be tolerably constant. When, however, we turn to the economy of fuel we find a different result, the total quantity used in Warren's being 23lb. of coal and 1lb. of wood, and in Deane's 71lb. of coal and 3lb. of wood. The coal used was a very fast burning inland coal. The ordinary allowance for forty-seven men being 50lb. of coal, it will be seen that the Warren apparatus was 27lb. or more than fifty per cent. under the allowance, whilst the Deane was 21lb. over. With regard to the third and fourth points—the quality of the food cooked, and the adaptability of the apparatus—the report states that in both cases the food was excellent, and that the Warren apparatus was specially adapted for the army, and was superior in many respects to the Deane boilers and ovens. These results are more than confirmed by the numerous reports from commanding officers, who speak very highly of Captain Warren's apparatus. In fact, most ample evidence was afforded by the viands which were prepared on the occasion of Captain Warren's lecture.

The saving to the country in the matter of coal for cooking in the army, resulting from this invention, is something very considerable. Taking the economy effected, as shown by the published reports, and putting the average cost of coal at £1 1s. per ton, we find a difference of £8,722 per annum at home, and quite independently of the Indian and other foreign establishments. Under these circumstances, then, it is but fair to expect that an officer, who has devoted so much time to the subject, and whose invention is admitted on all hands to be of the most perfect character, should receive some acknowledgment of his important services. This view of the subject, of course, formed no part of the lecture, nor was it in any way referred to. But we happen to know that the question has been raised elsewhere, and we hope it will not be lost sight of until it has been satisfactorily answered. The truth is, Captain Warren has applied to the War Office for remuneration, and after a great deal of hard fighting we believe he managed to obtain his travelling expenses—which, however, were reduced to £78—and £240, for nearly two years' constant work, after having proved how a saving of fifty per cent. in fuel could be effected. We are glad to say that Captain Warren was awarded a medal by the jurors of the Paris Exhibition, where the apparatus was shown. This led him to entertain renewed hopes of reward from his own Government, but these hopes have not yet been realized; so, as a last resource, the gallant Captain has written to the Secretary of State for War, setting forth the whole facts of the case, and asking to be placed on the same footing as other inventors. The War Office Circular, No. 942, March 3, 1866, states that "no invention will be adopted into the service without considering the claims of the person interested to a suitable remuneration." Captain Warren's invention has been adopted into the service, and we think that the least that can be done is to remunerate him in a suitable manner. Precedents for such rewards are to be found in the case of Captain Grant, the pioneer of reform in army cooking, and in those of Colonel Boxer and Major Palliser. In accordance, therefore, with these precedents—which we could easily multiply—we unhesitatingly say it will be a crying shame if reward is withheld from one who has so benefited the army and the nation.

SOIREE OF THE ROYAL SOCIETY.

THE second soirée of the Royal Society for the present year was given last Saturday evening by General Sabine, R.A., the President of the Society, and, as on the first occasion, proved highly attractive. It might aptly be termed an electrical evening, so greatly did apparatus in this branch of science preponderate. The rooms were thronged throughout the evening by a distinguished company of *savants*, who gathered round the General to the number of about 400. The company included all the Vice-Presidents, principal officers, and a very large number of Fellows of the Royal Society, also men of mark in politics, diplomacy, law, and physic, among whom were Lord Chelmsford, Sir H. Keating, Sir C. Trevelyan, the Persian Minister, the Swedish Minister, Viscount Eversley, Sir W. Erle, the Dean of Ely, the Dean of Chichester, Sir C. Wentworth Dilke, Sir J. Pennefather, the Earl of Mountcharles, &c., &c.

Turning to the electrical apparatus, we will first notice Mr. Apps' collection. Here we found an improved magnet and dia-magnetic apparatus combined, which is capable of sustaining 5cwt. with the current from a single cell. There was also an improved arrangement of vacuum tubes in connection with a large electro-magnetic engine, and a galvanometer of greatly improved construction. By this latter instrument currents from the lowest to the highest power may be tested with equal facility. The chief point of interest, however, was Mr. Apps' patent inductorium, which gave sparks 18in. in length through air. The discharges from a very large size Leyden jar, arranged as a secondary condenser according to Mr. Grove's original experiment, were from 3in. to 4in. in length, extremely thick and rapid. The great advantage of these induction coils over others is, that the insulation is permanent. There is a great saving of battery power, the contact breaker acts perfectly regular, and is under

Digitized by Google

very easy control, and either small or large battery power may be used. For heating or calorific effects, and for experiments with the Leyden jar and fulminating or snapping panes, two or three times the usual battery power may be used. For a given battery power, the effects are more than double those produced by coils on the old system. Many experiments, quite impossible with other coils, can be tried with safety; such, for instance, as that of testing the nature of the induction of the secondary upon the primary wire at the moment of discharge. Any experiment involving a connection between the primary and secondary may be performed with safety. Comment from us upon the merits of Mr. Apps' inductorium is superfluous in the face of the remark made by Mr. Grove at the soirée, that the coil was "decidedly the finest and most powerful he had ever seen."

Mr. Ladd exhibited a new form of break to be used with inductoriums, which was constructed by him from a design by Mr. Jerry Barrett. It was shown in action with M. Gassiot's large induction coil, which gave 12in. sparks. The object obtained by this break is, that it is self-acting, and, by a peculiar arrangement of a second hammer, long sparks can be obtained with great regularity and rapidity. Mr. Ladd also showed a new form of mercurial air-pump with which a vacuum of the most perfect description could be obtained. A new form of medical magneto machine by Mr. Ladd, with a circular magnet giving the currents all in one direction, was used to decompose water in a small cell under a microscope, which it did very freely, showing great power for so small and compact a machine. On the same table was also exhibited Mr. Warren De la Rue's new battery, consisting of 200 cells, by which an electric light was shown. In this battery chloride of silver takes the place of the copper or platinum of ordinary batteries. Mr. J. Browning had several astronomical instruments, and an excellent little magneto-electrical machine, in which the current flows continuously in one direction. This instrument is for medical use, for which purpose it is most appropriate, on account of the continuity of the current. The magnet is bent in a circular curve, and thus one bobbin only is required. Mr. Cromwell F. Varley exhibited and worked a most interesting and highly ingenious system of artificial telegraph cables, by which he showed the retardation of electric signals through long circuits by electrostatic induction. We also observed some original electric machines, by the same gentleman, for converting mechanical force direct into electric power without friction, by influence only. Considerable interest was taken by the company in some beautiful experiments showing the advanced state of stratification produced by electricity in phosphoric vacua, which was shown by a machine exhibited by Mr. Jerry Barrett.

Captain Colomb, R.N., with whose system of flashing signals our readers are familiar, exhibited, in conjunction with Captain Bolton, of the 12th Regiment, a new signal light, to which the name of the Chatham light has been given. This light has been designed to meet the want of a safe, powerful, and cheap light for signalling by means of the flashing system. It is certainly the simplest and cheapest portable signal light we have seen. It consists of a lamp on the top of a pole in communication with a box of inflammable powder and a pair of hand-worked bellows, which blow the powder in puffs across the flame when it ignites. To enter a little more into detail, we may observe that an outer chamber, below the flame of the lamp, is filled with a powder termed "Chatham powder." This powder is highly inflammable when burned in the Chatham light, but will not ignite in any other way. The outer chamber being filled with the powder, closes up the bottom of an inner chamber, and leaves an air space therein. By means of the bellows a current of air is made to pass up an air-hole, which current finally emerges in a sharp jet from an opening. This jet of air striking on the surface of the powder (which is very light) disturbs it, and mixes it thoroughly with the loose air in the inner chamber. This air, so mingled with the powder thus held in suspension, issues in two jets from two pipes. Between and below the mouths of these two pipes is the flame of a spirit lamp. The jets of air charged with Chatham powder meeting above this flame, at once burst into the most brilliant and dazzling light. So long, therefore, as pressure is kept up on the bellows, the light is continuous, but the moment pressure ceases, the light ceases also. In this way the long and short flashes necessary for making signals are produced with the greatest ease and certainty. The light is surrounded by a glass cylinder, in order to protect it from rain and wind, and within it is a gauze cylinder to protect the glass from heat. The present lamps are made for a range of about ten miles, but there is no actual limit to the range of the light, as this can be varied in the same lamp by varying the strength of the powder. This apparatus has been adopted for the Abyssinian Expedition, a number of the lamps having been taken out by the Signal Corps. This lamp appears to possess the necessary requirements for the purpose to which it is applied. There are no springs or any parts likely to get out of order, and the lamp may be trusted in the roughest and most inexperienced hands.

Mr. E. J. Reed, the Chief Constructor of the Navy, exhibited some beautiful models of ships in the entrance saloon. There was a model of the "Invincible," showing the system of upper deck batteries with all-round fire. There was also a model of the new Indian troop-ship "Serapis," full rigged, and a model design for an armour-plated breast-work monitor of 10,000 indicated horse power, and fifteen knots speed, having 15in. armour on the hull, and 18in. on the turrets. Mr. F. N. Gisborne exhibited his mechanical engine-room signals, and some specimens of auriferous quartz from the gold reefs of Nova Scotia. The steering compass has recently been greatly improved by the Earl of Caithness, and one of these gravitating compasses was exhibited by Mr. W. Nunn. We shall not allude further to the subject here, as we hope shortly to place it in detail before our readers. Mr. Nunn also exhibited his convertible signal lamp, which will be found fully described and illustrated in the MECHANICS' MAGAZINE for March 24, 1865. It suffices, therefore, to mention here that this lamp meets all the requirements of the Order in Council, dated January 9, 1863, which regulates the lights to be carried by small yachts, fishing vessels, and similar craft. This lamp renders it unnecessary for this class of vessels to carry more than one lamp. It is so constructed that, when the vessel is under weigh, the green and red lights can be shown at a moment's notice, and in such a manner that the green light shall not be visible on the port side, nor the red light on the starboard side; either can be shown separately, or the light can be entirely darkened at pleasure. When boats are at anchor, or attached to their nets, the same lamp, by a very simple contrivance, can be instantly converted into a globular anchor lamp, showing an unbroken light all round the horizon. In addition to this lamp, Mr. Nunn exhibited his binnacle for enabling mariners to take cross bearings.

Messrs. Weir's atmospheric telegraph apparatus attracted attention, on account of its simplicity and efficient action. These signals are now being fitted on board some of our war steamers, for steering and engine-room purposes, for which they are specially adapted. The operator can, with his thumb and finger, give all his orders. Tell-tales on the dial of the communicator, moving automatically by connection with the engine shaft or rudder, instantly communicate the fact of orders being or not being obeyed. These signals are most effective for ships in preventing collisions at sea, and by their instantaneous action are very valuable in fogs, when the common system of giving orders by the motion of the hand, or even by lights, would be unintelligible. In war steamers entering an enemy's port at night, all orders can be given and received instantly and noiselessly without a word being spoken. The communicator being portable can be readily and quickly removed to any part of the ship. Messrs. Weir exhibited three other applications of their atmospheric telegraph. First, a model was shown of a railway engine, passenger carriage, and guard's van. In the railway engine a bell is placed, which is connected with a small tube leading to the guard's van, and attached to a metallic flexible sided air vessel, to which is attached a push or button. The guard can, by pressing his thumb on this button, ring a bell near the engine driver. A similar air chamber and button is placed in each passenger compartment, and on a passenger pressing his thumb on this button a bell will ring upon the engine as well as in the guard's van. But to deter passengers from using these bells unnecessarily, the button, on being pressed, locks itself, and it cannot be replaced until the guard unlocks it. At the moment of pressing the button and giving the alarm, a shutter is thrown out from the side of the carriage, which shows the guard in which compartment the alarm has been given. The connection between the carriages is very simple, and the coupling and uncoupling is accomplished instantaneously. Second, an apparatus (also shown by model) is placed under the rail about a mile or so from the station to which the train is approaching. When the train passes over this spot a bell rings at the station, giving warning that the train is coming. Before the train enters the station it passes over a similar apparatus, which at once, by a pneumatic tube leading to the warning signals, blocks the line with lights and the semaphore arm, and the line thus remains blocked until the porter removes it with his haul. The third application was shown by another apparatus, by which, on pressing the thumb on a button, the bell rings at a distance, and at the same time a shutter rises and discloses the order. Thus it will be seen that the atmospheric principle, as patented, can be applied to a variety of purposes in every-day use. The value of this principle is its great simplicity, uniformity of action, and non-liability to get out of order. We may add that the apparatus can be seen at all times at 10, Philpot-lane, London.

Amongst the various apparatus of a miscellaneous but interesting character may be noticed an excellent machine for testing aneroid barometers by slow exhaustion, which was constructed by Messrs. Elliot, and exhibited by Colonel Strange. There was also a model illustrating the action of one of the applications of Captain Moncrieff's protected barbette system, as applied to a 7-inch rifled gun. A practical trial of this invention is being arranged, and we hope soon to place all particulars before our readers. Nicholl's system of bituminous cables for underground telegraphs was also shown. It is laid in 10ft. lengths, and the joints are simple, strong, and rapidly made. The insulating material is not liable to decomposition, and four men can, in one day, lay one mile of cable, containing several wires, and which are not liable to wilful or accidental damage. It is stated that the cost does not exceed that of any existing system. Mr. Henry Perigal sent a dissected model of the coffer in the Great Pyramid of Gizeh, showing that the same component parts will form the walls and bottom, or will exactly fill the interior, of the coffer. Says Mr. Perigal:—Each end = one-ninth of interior = half one side; each

Digitized by Google

side = two-ninths of interior; ends + sides = walls = two-thirds of interior; bottom = one-third of interior = half of walls; interior = half of exterior volume. Professor W. H. Miller exhibited a most interesting Clepsydra clock, or frictionless escapement, which deserved a more prominent position than it occupied. Messrs. T. Cooke and Sons exhibited two important inventions. One was a clock for giving motion to the great equatorial refracting telescope, constructed for Mr. R. S. Newhall, and the other was a sidereal and mean time clock, in which one of the times is converted into the other by a system of light wheels. There were, besides, numerous paintings, drawings, and statues, and the rooms were decorated with some choice and rare plants and flowers, lent by the Royal Botanic Society, which added to the pleasure of the evening.

THE INSTITUTE OF NAVAL ARCHITECTS.

IN continuing our notice of the interesting papers read at the recent meeting of this Society, we first turn to the Chief Constructor of the Navy, who is one of the vice-presidents of this Institution, and who contributed a very valuable paper, the object of which was to show that monitors are a class of vessel which cannot be trusted at sea under canvas. Before he proceeded to the immediate subject of his paper, Mr. Reed pointed out the difference of stability as the term is usually understood by theoretical men and as it is employed by nautical men, as a synonym for steadiness; and it was one of the most convincing arguments Mr. Reed could have used, had he wished to teach us the lesson that we must be sure of the meaning of the terms we use before we can begin to argue upon them, when he showed that the "Achilles," which has earned the reputation of being the steadiest ironclad in our Channel fleet, owes that reputation to the fact of its having the least stability; while, on the other hand, the "Lord Clyde," whose stability is great, is a very ugly roller. Another important point not neglected was the difference between statical and dynamical stability. The former is the moment of the couple formed by the two equal forces, the weight of the ship acting downwards through its centre of gravity, and the buoyancy acting upwards through the centre of buoyancy, when the ship is heeled over to any angle; while the latter is the work necessary to heel the ship from its upright position over to that angle. If a curve be drawn whose abscissæ represent different angles of heel, and ordinates represent the statical stability at those angles, the area between any ordinate, the curve, and the line on which the abscissæ are measured, will represent the dynamical stability. Mr. Reed exhibited some diagrams of the curves so obtained for the "Duncan" as it is, cutdown to a freeboard of 3ft. 6in., and fitted with two heavy turrets, and the "Duncan" as it was once. Formerly, the statical stability varied very nearly as the angle of heel, the consequence of which was that under canvas it would have been a safe vessel. The moment of the wind on the sails decreasing with the inclination, and the stability increasing, must, in time, become equal, and, after that, the stability having the better of the wind, brings the ship to rest. Under the action of these two forces, the vessel will oscillate about the position which, after a time (considering the wind uniform), it will take up, owing to friction, and then the two forces will have equal moments, and the ship will remain inclined at a constant angle of heel.

For small angles of heel, all this is true for the "Duncan" monitor, but as soon as we come to an inclination of only 7deg., the edge of the deck comes to the level of the water, and the law of stability suffers a break of continuity. The stability still increases, but only until 10½deg. is reached, after which it steadily decreases, and before we get to 25deg. it has vanished. The buoyancy of the vessel after that helps the wind to turn her over. We cannot conceive a vessel endowed with more dangerous properties than this. Take the same vessel weighted so that its freeboard is diminished to 2ft. 6in., and, again, 2ft. Instead of a maximum stability occurring at 10½deg., it now is met with as early as 8deg. and 6½deg. respectively, and the angle for which the stability is zero has shifted to 18½deg. and 16deg. respectively. This is quite enough to convince us that a berth on a monitor under canvas in a stiff breeze is anything but desirable, except to persons of a suicidal turn of mind. In fact, we entirely believe that it would be little short of madness in the captain of a monitor to make any great use of his sailing power; in other words, monitors are not fit to go to sea. They are fair weather sailers, and nothing more. One has recently been built for the Melbourne Government, and a temporary side and upper deck were thought necessary to give it anything like a fair chance of finding its way to the Antipodes.

With reference to dynamical stability, we may say that Mr. Reed's diagram showed clearly that the "Duncan" as a monitor, with 3ft. 6in. freeboard, had, in dynamical stability, scarcely half of what it had before its conversion, and that, reducing the freeboard as before to 2ft. 6in. and 2ft., we reduce the dynamical stability, in the first case, to one-third of what it has with its present freeboard, and in the latter case to practically nothing.

An interesting discussion followed this paper, but we are sorry to be forced to say that the opening of this discussion was disfigured by a personal attack on Mr. Reed. Had his assailant's language been half as expressive as his tone, we think he must have been shown the door, but, luckily for him, his eloquence is not of the highest order, and he escaped with a slap in the face from Mr. Scott Russell, and a quiet lecture from Dr. Woolley.

Muzzle-pivoting gun carriages for naval armaments are now demanding and securing great attention on all sides. It was always a matter of moment to save our men and guns from the action of an adversary's projectiles, but now that guns cost from ten to one hundred times as much as formerly, and the men to work them are hardly to be got at any price, to protect both has become a vital question. The narrow loopholes and embrasures of the past, show the value of this protection in the opinion of our ancestors, but now, with the whole of the broadside of the old 74 combined into a single gun, or, at most, some half-dozen, it is evident our risks are commensurately increased, and we are staking our safety, or perhaps our existence, on a single cast of the die. To narrow our ports, and thus afford protection, is further necessitated by the lengthened inaction of the guns. The massive machines now in use, and the ponderous projectiles which they gorge, cannot be manipulated in a hurry. Tons of metal have now to be handled, where our forefathers saw difficulties in cwts. In the paper read by Captain Heathorn, R.A., we have many points of great interest brought out in connection with muzzle-pivoting guns. The methods he divides into the following classes:—1. Those that absolutely or approximately muzzle-pivot a gun on a fixed material pivot. 2. Those that do the same thing on an imaginary pivot. 3. Those that, using the imaginary pivot, have the mechanical arrangement for producing muzzle-pivoting motion wholly apart and separate from that employed to lift the body of the gun through the necessary passage in space, which necessity is, of course, common to all. The Captain promised to enlarge on this subject at the United Service Institution, in a paper he has since read. We have been on the *qui vive*, for the benefit of our readers, to see the additional light which he is well qualified to throw upon this interesting and important matter, and the paper has already been noticed in this journal. In minimum embrasures we think we see the great desideratum of more complete protection to the men and materials of our ships of war; and as ofttimes per contra reasoning and examples (partaking of the *reductio ad absurdum*) are most powerful auxiliaries to the direct argument, so we think that the instructive experience of large ports in the case of the Brazilian war vessels, instanced by Mr. Barnaby, must act as a serious warning to them and to us.

At the Friday morning meeting, Lord Hardwicke in the chair, Vice-Admiral Sir Edward Belcher, K.C.B., read a somewhat lengthy paper on naval construction from 1800 to the present time. It is manifest that such a review must afford ample scope to even a superficial observer, of whom we do not mean to call Sir Edward one. His paper, indeed, brings forward many points of great interest, and, in regard to our present modes of construction, of unsurpassed importance. It must be conceded on all hands that our ironclad fleets are not intended to keep the seas. They are wholly incapacitated for that by their heavy draught, and consequent want of speed; their unseaworthiness, their contracted stowage of fuel, and for other reasons. They must, therefore, be chiefly used, if used at all, in home and harbour defence. This at once compels us to have as many fleets as we have homes to defend—no small matter, considering the fabulous sums our ships now cost. Bnt it has always struck us as a probable result of the present construction of armour clads, rams, &c., that whenever they shall be called into action, we shall experience a woeful disappointment, if not suffer an irreparable catastrophe. If a ram, for instance, can get a fair opportunity to have "a go" at an adversary, no doubt she will inflict serious if not fatal damage. But what of herself? How is she to get free from the wreck which she has wrought? Wasp-like, she may sting, but, whether leaving her sting behind or not, she will in all probability pay the forfeit of her own existence. It is not so certain, however, that she will be able to secure at will a favourable position and opportunity for an assault. The unwieldy projecting submerged ram will be to herself a source of constant trouble and danger. Sir Edward considers the best form of ram to be the overhanging prow of ships of good speed; for these would, as he says of the "Warrior," "make terrific rams above water." The impact of the submerged ram on her adversary would tend to throw it inwards on to herself, while the "Warrior"-like ram would throw the adversary outwards on to her beam ends, cut her down, and finally run over her. A struggle between two of our large unwieldy ironclads at close quarters, if such could be imagined, must be war *a l'outrance*. It would be the tale of the Kilkenny cats once again, with only this difference, that these respectable mythic animals left their caudal extensions to point the moral of their fate, while our unmanageable, panting mammoths, with a slight variety of the nursery rhymes—

> "Would never come home,
> But leave their tales behind them."

Sir Edward introduces also the consideration of modes of propulsion. However valuable screws may be, they are exceedingly liable to injury from shot or fouling. The turbine is wholly exempt from such risks, and, moreover, aids the rudder in rapidly turning the vessel, almost as if it were on a pivot. After the lapse of the conventional twenty years of probation, or reprobation, at the Admiralty, this principle has had a trial. But we think with the speakers on this paper,

Digitized by Google

that it would be well if some suggestive board were established to recommend inventions of promise to the authorities. This would do away with the system of "dry-nursing" and "stepmothers" to which the mental bantlings of inventors are now too subject, and prevent the transfer to other countries of ideas which might be judiciously worked up into important principles. We cannot sum up our opinions on this paper better than in the words of the noble chairman; and wishing Sir Edward somewhat of a clearer style, and a better reporter, with sincerity we say to him "go a-head." The chairman's remarks were:—"The question raised by my excellent friend Admiral Belcher is for the purpose of endeavouring to elicit from us a prophecy as to what will be the future of the navy. Gentlemen, I will venture to prophesy that within the next twenty-five years or thirty years ships will be propelled by steam—that there is no doubt of. The form of propulsion will be the turbine. The vessels will be full-rigged, and the armour-plate will be very much reduced, but not lost sight of. That is my prophecy as to what will happen in twenty-five years."

ELECTRICITY AND TELEGRAPHY.

WE are happy to announce that the Malta and Alexandria Telegraph has at length been repaired. The repairs were successfully completed on the 25th ult. The great delay has been owing partly to the inclement weather preventing the "Hawk" from attempting any operations, and partly from the number of faults that have taken place. It is to the circumstance of the re-opening of this cable that we probably owe the fact of having the late glorious news from Abyssinia so soon. Considering the distance that had to be traversed over such a difficult country, and the amount of sea passage up the Red Sea, it must be acknowledged that the message from Magdala, arriving within a fortnight of the victory, deserves mention as being a case of extraordinary despatch.

The Persian Gulf cable continues to be interrupted, and in consequence of the repairing ship, the "Amber Witch," being at Bombay undergoing repairs, it is very probable that it will be some time before communication will be again restored. In order to expedite messages over the broken section, steamer arrangements have been completed between Gwador and Mussendom for the conveyance of messages, so that the delay in the transit over that section is now expected not to exceed from forty to ninety hours.

We lately announced the presence over here of General Smith, President of the International Ocean Telegraph Company, for the purpose of having a second cable made and laid between Key West, Florida, and the Havana. The contract for the cable has been given to the India-rubber, Gutta-percha, and Telegraph Works Company, who are now progressing rapidly with its manufacture at their works at Silvertown. The cable is to be slightly shorter than the previous one, and is protected externally by a bituminous compound outside the galvanized iron wires. Sir Charles Bright is the superintending engineer for the American company, who are, on this occasion, going to lay the cable themselves. We believe Sir Charles goes out to lay the cable for them. The steamship "Narva" is engaged for this work, in consequence of her being found so well qualified for it as she proved on the first occasion. The expedition will leave England about a month earlier this year, so it is to be hoped that the work may be successfully accomplished before the sick season sets in.

We hear that there is a strong probability of the extension of telegraphic communication to Jamaica and to Panama, a company having been specially formed for that purpose in America. A proposition has been brought before the Jamaica Legislature for connecting that island with the United States. The cable now working so successfully between Florida and the Island of Cuba has materially increased confidence in submarine lines, and we hope shortly to hear of some definite steps being taken with the view of bringing about more extended communication with the West Indies.

For the first time, some experiments on a large scale of military telegraphy are to take place this year at the camp of Chalons; for this purpose several employés of the French telegraph lines have been drafted off and placed under officers specially appointed.

The Mexican Government have just given to M. Villarti a concession for a telegraphic line from Leon to the coast, and placing Mexico in communication with the Mexican ports of the Pacific. The works of the line from San Luis-Potosi to Matamoras are rapidly advancing. This system once complete there will then only remain to construct one section between Brownsville and Saint Antonio—Texas—to place Mexico itself in direct communication with New York.

M. Gerard has lately tried a most interesting experiment, which he has communicated to the Academy of Sciences, at Paris, in which he sees a new system of electric telegraphy, and he believes that later we shall be able to succeed in obtaining from this principle very powerful machines. His experiment is simply placing above an electro-magnet a metallic ring formed of wire of a greatly but regularly varying diameter, so that on the one side the wire is very fine, on the other very thick. These conditions being fulfilled, the electro-magnet when excited is capable of giving movement to the ring.

We lately noticed the fact that in the electric light the current could be spontaneously re-established after a cessation of a small amount—about the twentieth of a second. This fact has been taken advantage of to illuminate two lights by the action of one current, the interruptions being made of less duration than the above time, the currents being sent in two different directions, and two lamps are kept consequently in a state of illumination. For each of these the interruption is very short, and the current is spontaneously re-established without the necessity of bringing the charcoal points together. Owing to the retention of an image upon the retina of the eye, the light, though intermittent, appears continuous.

We learn from "Cosmos" that M. Leroux has obtained from the following expedient an electric light of a fixedness and an intensity greater than by the machines usually employed. In a certain direction he throws a small jet of oxygen upon the incandescent carbon; they waste slower, and the voltaic arc, in place of a variable oscillation on account of the impurities of the carbon, rests fixed in the position opposite to the oxygen jet, showing on that face the greatest quantity of the illuminating power of the lamp.

The Indo-European Telegraph Company have just issued their prospectus, and so favourably has the scheme been received that the applications for shares in the various continental towns greatly exceed in number those allotted to them. We may, therefore, hope to see almost immediate steps taken to commence this work, and probably by this time next year we may be able to congratulate our readers upon direct communication with India. Of the plans brought before the public none offer so speedy, direct, and economical a means as the present. Agreements have been concluded with the Electric and International Telegraph and Reuter's Telegram Companies for the use of two wires from London to the Prussian coast, and from that point a concession has been obtained from the Prussian Government who undertake to erect at their cost two wires to Thorn, and concessions are also obtained from the Russian and Persian Governments for the erection of two wires from Thorn, via the Black Sea, which is coasted by a submarine cable to avoid the mountainous passes in Asia, to Teheran. Messages passing through have to pay certain royalties to each government, but the charge per message, deducting these royalties, working expenses, and other charges, will leave ample room for profit. The concession and all arrangements have been carried out and obtained by the Messrs. Siemens, who hand over their rights to the company, and who undertake the necessary work, which, with their large continental staff, will be a comparatively easy undertaking. The difficulty hitherto experienced in obtaining a line through the various states of Europe has, through the exertions of the Messrs. Siemens, assisted by some Government influence, been overcome, and we may therefore congratulate ourselves that we have obtained now, through them, certainty almost absolute, of a direct and uninterrupted communication with our possessions in the East. We may, therefore, expect that, by the employ of our experienced operators, messages will be received with but little transmission, and free from those sources of error which heretofore have rendered our telegraphic service with the East a hazardous proceeding.

Opposition to the Government Telegraph Bill has set in, and we have now before us a pamphlet stating the case of the Electric and International Telegraph Company against the Government project. We have also the parliamentary papers giving the reports to the Government in favour of it; press of matter prevents us from discussing the question in our present number, but we hope next week to give our readers some details of this subject.

PHOTOGRAPHY.

ACTINOMETERS—WASHING APPARATUS FOR SILVER PRINTS—NEW MATERIAL FOR PHOTOGRAPHIC DISHES—ALLEGED EXTRAORDINARY PHOTOGRAPHIC DISCOVERY.

IN several photographic processes a sensitive and reliable actinometer would be very valuable. In carbon printing an actinometer is a great aid, because the picture cannot be seen as it is produced by light, so that only in the subsequent washing operations does the operator discover, whether or not the film has been long enough exposed, and then it is too late to remedy any defect. Out of the numerous methods of approximately measuring the chemical activity of light, Professor Roscoe's more scientific methods are not found to be practically useful in photography, and the only plans hitherto brought into commercial use are very simple. Mr. Bing made a "step-by-step" actinometer consisting of many sheets of glass each successive piece being rather smaller than its predecessor. These were laid over each other, the largest downwards, so as to form a flat ladder, the light at one end of the bundle having to penetrate only one sheet of glass, but at the other end having to penetrate the whole number, whilst between the two ends it had to penetrate all the different thicknesses successively. When a piece of sensitive silver or bichromate paper is placed beneath such an arrangement, it will first be changed by light where the glass is thin, but as the layers grow thicker, the chemical change is retarded in proportion. Each thickness of glass is numbered, and the paper used must always be prepared in the same way, so that it shall not vary in sensitiveness. With every new negative, the amount of actinic action it requires to print properly must be ascertained by comparison with the foregoing little instrument, and when this is once done, and the negative marked with the number of the actinometric thickness of glass, which corresponds with the time it must be exposed to light, the actinometer will in future give evidence when the film has been subjected to light the proper time. Dr. Vogel has since made a new little actinometer on the same principle, different thicknesses of paper being substituted for the different thicknesses of glass.

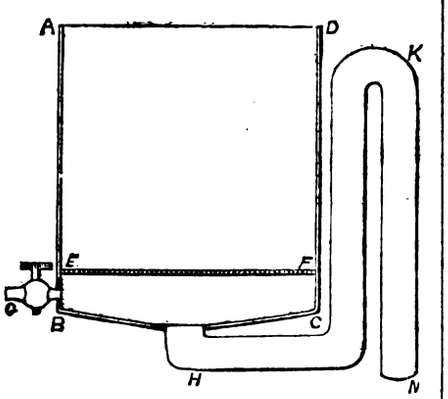
Such actinometers, likewise the more scientific contrivances of Professor Roscoe, only give the aggregate amount of actinic action after the lapse of a prolonged space of time. They do not show the momentary changes caused by every passing cloud, and other atmospheric influences, and are of no value in instantaneous photography. Every photographer who has practised this beautiful and difficult branch of the science, knows that there are great differences in the light, which one day enable him to get rapid pictures with comparative ease, and on another render his attempts hopeless, though to the eye and memory both days may appear to be equally sunshiny and bright. The chemicals and lenses may be alike in both instances, so that the differences cannot be laid at their door. Moreover, the records that were taken for a time at the observatory of the British Association, at Kew, show on special days a very great increase above the average in the chemical intensity of daylight. It would thus be a great boon to the instantaneous photographer if he could know not only the days when the actinic rays penetrate the atmosphere most freely, but the very moment when he can expose his plate to most advantage. At present the only mode by which this can be done is by the actinometer described some weeks ago in these columns, wherein a method is pointed out of making an iron needle

Digitized by Google

swing round in proportion to the amount of actinism present each instant in the etherial waves.

To make the present silver prints as durable as possible, thorough washing in many changes of water is absolutely necessary directly the pictures are finished. An efficient method of doing this, when only a few pictures are to be washed, is to lay them one by one upon a plate or other slab of porcelain, then, beneath a tap of running water, sponge them well on both sides. The sponge sucks out the chemicals which adhere so persistently to the pores of the paper, so that after five minutes' treatment in this way, and half an hour's subsequent soaking in running water, the prints are better washed than if simply left for many hours in running water, in the usual way. Moreover, quick washing preserves the brilliancy of the prints in a greater degree.

In commerce, this amount of attention can rarely be given to the washing of great numbers of prints, so that numerous washing machines have been invented, some of them also being very objectionable. Mr. G. Dawson, M.A., of King's College, showed us last week a very ingenious and simple washing machine, just brought under photographic notice by an anonymous writer in one of the journals. It is found so efficient that already two or three persons are claiming to be the real and original inventors of the same, though it would seem that such a trivial matter is scarcely



worth quarrelling about. The accompanying cut shows the principle of the apparatus. A B C D is a zinc tank, with a false bottom made of perforated zinc at E F. The prints are put in the upper part of this vessel, and water from a large source of supply is turned on through the tap G. It then enters the tank, rises through the perforated zinc, and lifts up the prints, which are thus kept moving in the water in the vessel. The tank thus gradually fills, but directly the level of the water nearly reaches the top A D, the great iron pipe H K N acts as a syphon, and lets all the water now impregnated with chemicals from the prints run away. This large pipe must be a little flattened at the bend K. After the water is thus all drawn off, the tank slowly fills again by the small stream constantly running through the tap G; when full it is again suddenly emptied, and so on as long as the operator pleases. Thus large quantities of prints may be left to themselves for hours, and the little hydraulic arrangement will wash them efficiently in successive changes of water.

We were shown at the same time, in the photographic laboratory at King's College, a method employed by Mr. Griggs, of the India Museum, to abolish the ordinary glass or porcelain photographic dishes, except for nitrate of silver solutions. His plan is to get a flat square piece of wood, the size of the dish required, and nail four narrow strips of wood upon it near the four edges, the ridge formed by these strips being intended to serve the purpose of the rim of the dish. Then he paints the bottom and sides with india-rubber solution, and, lastly, presses down all over the wooden dish a sheet of "Hancock's india-rubber canvas," and nails the extreme edges down over the outside of the tray. This canvas costs only about 2s. 3d. per square yard, so that dishes thus made are much cheaper than those made of glass or porcelain, and are not liable to breakage. They are not well fitted for nitrate of silver solutions, but other photographic chemicals may be used in them with impunity.

A provincial photographer, of the name of M'Lachlan, for some months past has been writing to the photographic periodicals, saying that he had made an important discovery, but would not publish it except upon some very complicated conditions, involving the appointment of a committee and other curious items. However, at the last meeting of the Photographic Society, in Conduit-street, he said that he had discovered that a solution of nitrate of silver, exposed for a long time to light, is changed in its chemical properties. He said that, if nitrate of silver be dissolved in water in the proportion of one ounce of the salt by weight to one ounce of the water by measure, and a portion of this solution be exposed to light for two or three months, its chemical and photographic characteristics will be altered. He alleged that if one drop of solution of caustic potash—strength, one grain to the ounce—be added to the unsunned nitrate solution, oxide of silver will be precipitated. But if the sunned portion be treated in the same way, the precipitate formed is immediately redissolved; in fact, this solution will bear a considerable addition of the weak potash solution before it will throw down a permanent precipitate. He said that the solution after being thus treated with potash possesses remarkable and useful photographic properties, which he has investigated for many years. He also stated what these new properties were, but it is scarcely worth while to reproduce the other statements here till the main fact about the change in nitrate of silver is authenticated. Mr. Glaisher, F.R.S., who presided at the meeting, asked Mr. M'Lachlan to write a paper on the subject, so that the different points of his discovery may be fully considered at the next meeting. This he promised to do. The society also at once appointed a committee to investigate the subject. Mr. M'Lachlan states that one of the results of his discovery is, that hundreds of negatives without spot or blemish may be taken consecutively with certainty in a small quantity of the improved bath solution. If these statements turn out to be correct, the importance of the discovery is very great, not only from a photographic point of view, but in consequence of the new field it seems to open for investigation in molecular physics. If the statements turn out to be inaccurate, the speaker thereof had better retire forthwith to those regions whence he came. The fact that bad samples of nitrate of silver may be very much improved for photographic use by sunning is not encouraging. When solution of nitrate of silver contaminated with organic matter is exposed for a few hours or days to sunlight, much of the impurity is precipitated.

Mr. Spiller, F.C.S., of Woolwich Arsenal, thinks that particular impurities in nitrate of silver may possibly cause the alleged change in the solution by sunlight, and he is trying experiments on the point.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

A MODE OF STOPPING POROUS CYLINDERS FOR HYDRAULIC PRESSES—A SIMPLE WAY OF BREAKING IRON—A PROCESS FOR OBTAINING PURE IRON—PROCESSES FOR TREATING SEWAGE.

KOHN, an engineer in Berlin, gives the following as a method of effectually stopping up a porous cylinder cast for a hydraulic press. The cylinder is to be heated over a charcoal fire to about 170deg. Fahr. It is then to be filled up with rosin and suspended by a crane over fire until the liquefied rosin is seen sweating through on the outside. The excess of rosin is then poured out and the cylinder allowed to cool, when the pores will be found completely stopped, and no water can possibly pass.

The same engineer gives a simple way of breaking a mass of iron, which we hardly think is novel In a mass 2ft. square and 4ft. long, he bored a perpendicular hole 1in. in diameter, and between 3in. and 4in. deep. This he filled with water and closed with an accurately fitting iron bolt. One heavy blow on this bolt broke the mass into two pieces.

Troost gives a method of obtaining very pure soft iron. He melts cast iron in a lime crucible by means of the oxy-hydrogen flame, directed downwards, we presume. When the metal is fused he increases the proportion of oxygen, and thus burns away the silicon, carbon, and sulphur. The slag formed is absorbed by the crucible. When the operation is finished, a button of very pure metal remains at the bottom of the crucible. This process would be extremely useful on the large scale if oxygen could be procured at a cheap rate, but pending the discovery of means whereby oxygen can be prepared for industrial purposes, pure iron obtained in this way must remain a metallurgical curiosity.

The question of the disposal and useful application of sewage is one that continues to agitate the public mind in London and a great many other cities. It may not be out of place, therefore, to refer to a report by Dumas, on a process recently experimented with at Paris. In carrying out this plan the sewage is collected in reservoirs, and precipitated with a solution of sulphate of alumina. The quantity is not stated, but the cost of the precipitant is said to be one centime to the cubic metre of sewage—that is, less than half a farthing a cubic yard. The precipitate is quickly deposited, and contains all the phosphoric acid, and nine-tenths of nitrogen, and organic matters in the original sewage, and it is therefore a valuable manure. The weight of dry precipitate obtained is six kilogrammes (7lbs.) per cubic metre. The supernatant liquor is limpid and completely deodorized, and may be run into a stream without any fear of disagreeable consequences. It is only right to say that the use of sulphate of alumina has been suggested in this country, but with addition of lime and sulphuric acid, which have greatly lessened the value of the precipitate for agricultural purposes. There are many towns in England where this precipitation by sulphate of alumina alone might perhaps be carried on with profit.

Another suggestion much less reasonable has been made for the extraction of ammonia from town sewage. The inventor of this process adds phosphoric acid and magnesia to the sewage, with the idea of precipitating the ammonia in the form of ammonio-magnesian phosphate. The precipitate he gets, he collects and dries, and then distils with quicklime in gas retorts, condensing the ammonia which passes over in the usual way. The residue in the retort will contain the phosphoric acid, and be applicable for manure. As a method of obtaining ammonia, this process is not worth a thought. But while writing on sewage, we may remark that a similar precipitation formed the subject of a patent by Mr. Blyth, the chemist to the Board of Health, which never, we think, attracted the attention it deserved. The patent has long expired, and the information contained in it is fully at the service of the public. The sewage being conducted into reservoirs, a calculated proportion of superphosphate of lime was added, and the mixture strongly agitated. Lime water was then added in sufficient quantity to render the whole rather alkaline. The mixture was again strongly agitated, and then allowed to deposit. A precipitate was thus obtained rich in ammonia, and all the suspended matters were carried down by it to the bottom of the reservoir. This we believe to be a valuable process, but it requires intelligent superintendence.

DR. LIVINGSTONE.

NOT less on account of the great explorer than on that of Dr. Stenhouse, will our readers be interested in the perusal of the following extract of a letter from Dr. Livingstone to Mr. James Young, the paraffin manufacturer, of Limefield:—"Country of the Chipeta, Feb. 1, 1867. I am sorry that I never could write to Dr. Stenhouse about his invention. The sheet his agent gave me to place on the ground beneath my bed has been invaluable as a tent overhead. He offered me a covering of a lighter kind, and I regret exceedingly not having accepted it. The Mackintosh sheets I have tried are not to be mentioned in comparison. This black sheet is lighter and lasts wonderfully, while the india-rubber sheet so glues itself together that you soon tear it to pieces in drawing the folds asunder. The first pair of boots have lasted during a five hundred mile tramp, often over a rough stony soil and in the driest and hottest season. I gave away the first pair, not because the uppers were broken or the soles worn out, but because the inner seam had given way at the toes and the heels were gone. I ought to have had a pair not Stenhoused to try against the others. I am now putting a second pair to a severe test daily, wet outside and in and then exposed to a broiling sun. If they last long at this I shall let the Doctor know. I think his invention really very valuable, and I wish you would give him this extract as a sort of acknowledgment for kindly providing that brick of a sheet."

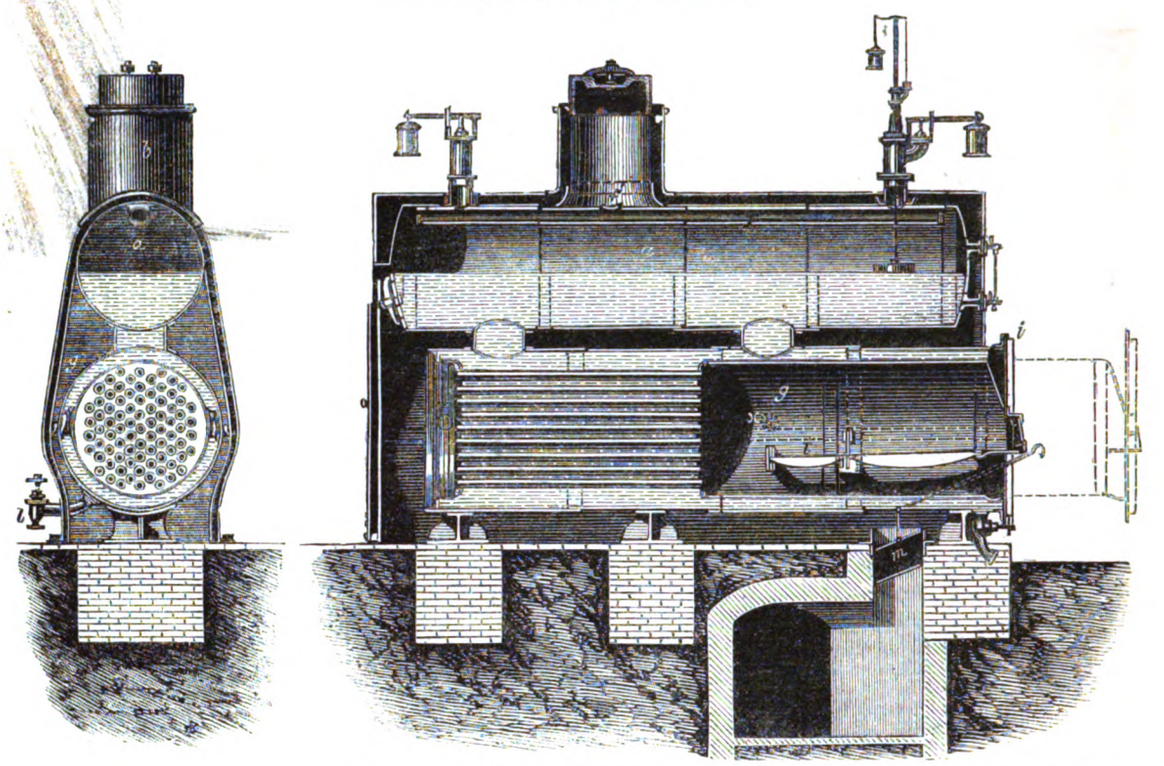
SPECIAL STEAM BOILER.

BY MESSRS. FARCOT AND SONS.

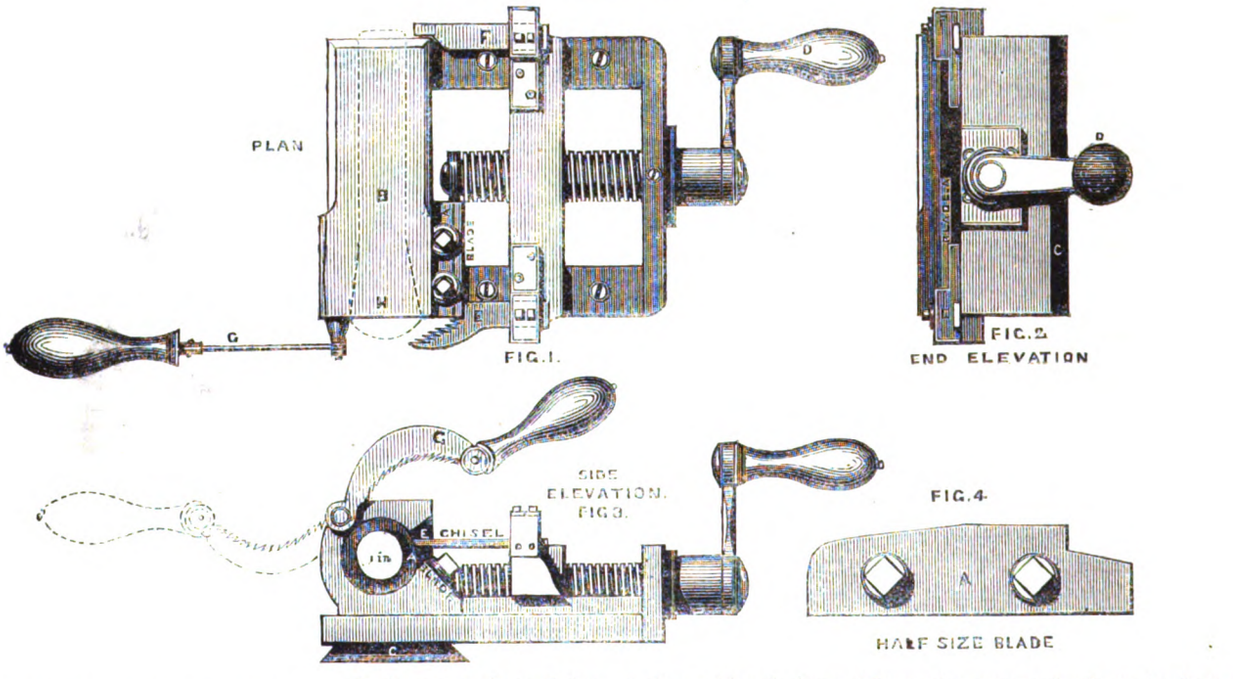


SPECIAL STEAM BOILER.

THE above illustration represents a boiler by Messrs. Farcot and Sons, of St. Ouen, and which is constructed after a system introduced by that firm. It will be seen from the engraving that the boiler consists of two chambers placed one above the other, and connected by waterways. The lower chamber contains the firegrate and tubes, and is so constructed that they may be drawn out for the purpose of cleaning them. The small rollers *v* and *x* are intended as supports to the tubes and grates when so removed. The whole boiler is surrounded by a casing of iron plates strengthened with angle irons, and which casing forms an external flue for conducting the heated gas from the lower boiler to the chimney.

PATENT TREENAIL CUTTER.

BY MR. ADDIS, C.E.



PATENT TREENAIL CUTTER.

MR. ADDIS, C.E., of Bombay, has recently patented the neat little mechanism for making treenails illustrated in the accompanying engraving. It is intended to facilitate and render perfect the formation of treenails which are being extensively used on some lines of railway. These machines have been successfully employed in the patentee's workshops, each machine delivering, on an average, 500 treenails a day, at a cost of 18 rupees a thousand. They were also effectually used at Erode, on the Madras Railway, where there were no provisions made for large deliveries, and their want seriously felt. The machine is a simple and inexpensive one, and consists of a single cutting tool A secured in a box B, which is rendered capable of being removed for repairs or renewals; the mode of operation is exceedingly simple, and can be conducted by an ordinary labourer. The timber for the purpose is first roughly shaped and cut into lengths from 18in. to 20in., so as to be admitted into the box B. One of the pieces is centred on a puppet, and by motion communicated in any convenient way is made to revolve. The machine, which is placed on the bed of a lathe, and by means of a

Digitized by Google

groove C, is slided forward, and on its approach to the wooden pin the chisel E is gently advanced by working the handle D, which serves to remove all superfluity on the surface of the intended treenails, which, during its transit through the box B, is formed and rendered smooth and clean by the cutter A within. After the pin has passed the whole length of the box B, the chisel E is worked home, which completes and finishes the treenail by forming the head, and adapting it for the cap, while the other end is bevelled by chisel E. Lastly, the saw G is pressed down on to the treenail, which detaches it from the puppet, leaving it formed, as shown by the dotted line H, in fig. 1. By the application of an inndependent motive power, so as to dispense with direct manual motion, the utility of these machines may be greatly enhanced. In the engraving, fig. 1 shows the machine in working order, with appliances for adjusting; figs. 2 and 3 side elevation. Fig. 4 represents the cutting blade of the machine.

A SEARCH FOR SOLID BODIES IN THE ATMOSPHERE.*

By Dr. R. Angus Smith.

I HAVE so frequently for many years attempted to find, and have found, organic substances which have passed from the air into liquids in which they were collected, that perhaps the Society will scarcely attend to another attempt although it indicates, I think, some progress. It was in the year 1847 that I first collected what I believe was matter from the respiration and perspiration, and found that as it was kept it grew into distinct confirmed forms. Whilst examining some matters relating to the cattle plague I found one or two remarkable points. I had before that time used aspirators to pass the air through liquids, except in the oxidation experiments. At that time I used simply a bottle which contained a little water. The bottle was filled with the air of the place and the water shaken in it. The difference of air was remarkable. A very few repetitions would cause the liquid to be muddy, and the particles found in many places were distinctly organic.

It may, however, interest the Society to hear of a few of these previous attempts, the latest made till recently. I shall therefore read from a report to be found in the appendix to that on the cattle plague.

Mr. Crookes also brought me some cotton through which air from an infected place had passed. It was examined at the same time. Taking cotton in the mass nothing decided was seen; but when it was washed some of the separate films were coated over with small—nearly round—bodies, presenting no structure, or at least only feeble traces of it, and perhaps to be called cells. I had not sent gun-cotton, as I intended, to Mr. Crookes, fearing the rules of the post; otherwise there would have been more certainty that the bodies spoken of did not exist previously on the cotton. However, Mr. Dancer, who has examined cotton with the microscope oftener than most persons, even of those experienced in the subject, had never observed a similar appearance. The liquid had also a number of similar bodies floating in it.

It was then that Mr. Crookes sent a liquid which he had condensed from the air of an infected cow-shed at a space a little above the head of a diseased cow. It was also examined, and it presented similar indications of very numerous small bodies. Not being a professed microscopist I shall not attempt a description, but add that they clearly belonged to the organic world, and were not in all cases mere débris. We found also one body a good deal larger than the rest; it resembled somewhat a paramecium, although clearly not one. We found no motion whatever, and only this latter substance could be adduced as an absolute proof of anything organized being present. Next day I examined the same liquid: and, whether from the fact of time being given for development or from other causes, there was a very adundant motion. There were at least six specimens in the field at a time, of a body resembling the euglena, although smaller than I have seen it. When these minute bodies occur it is clear that more may exist, and germs in this early stage are too indefinite to be described. The existence of vital sparks in the organic substances in the air alluded to is all I wish to assert, confirming by a different method the observations of others. It might, of course, be said that since the bottle was opened at Mr. Dancer's the air at that place may have communicated them. I answer that, before it was opened, a good glass could detect floating matter, some of it, however, as in the microscope proved, indefinite enough.

Finding this, and fearing that the long time needful to collect liquid from the atmosphere might expose it also to much dust, I used a bottle of about 100 cubic inches dimensions, and putting with it a very little water, not above five cub. centimetres, I pumped out the air of the bottle, allowing the air of the place to enter. This was done six times for each sample, the water shaken each time, and the result examined. This was done with the same bottle that was used in my early experiments with permanganate, and by the same method, except that water instead of that salt was used. At first considerable numbers of moving particles were found; but it was needful to examine the water used, and here occurred a difficulty. It was not until we had carefully treated with chemicals and then distilled the water again and again that we could trust it. Particles seemed to rise with the vapour, and if so, why not with the evaporating water of impure places.

Having kept an assistant at the work for a week, and having myself examined the air of three cow-houses, I came to the conclusion that the air of cow-houses and stables is to be recognized as containing more particles than the air of the street in which my laboratory is, and of the room in which I sit, and that it contains minute bodies, which sometimes move, if not at first, yet after a time, even if the bottle has not been opened in the interval. There is found in reality a considerable mass of débris with hairs or fine fibres, which even the eye, or at least a good pocket lens, can detect. After making about two dozen trials, we have not been able to obtain it otherwise. Even in the quiet office at the laboratory there seemed some indications.

I found similar indications in the cow-house with healthy cows; so I do not pretend to have distinguished the poison of cattle plague in these forms; but it is clear that where these exist there may be room for any ferment or fomites of disease; and I do not doubt that one class is the poison itself in its earliest stage. It would be interesting to develope it farther. I have recorded elsewhere that I condensed the liquid from the air of a flower garden, and found in it, or imagined I found, the smell of flowers. I do not remember that I looked much to the solid or floating particles, thinking them to be blown from the ground, but it does not effect the result, whether they be found constantly in the air or are raised by the action of currents.

Lately I tried the same plan on a larger scale. A bottle of the capacity of 4990 c.c. was filled with air and shaken with water. The bottle was again filled and shaken with the same water, and this was repeated 500 times, nearly equal to 2½ million cbc., or 2,495 litres. As this could not be done in a short time, there were considerable variety of weather, but chiefly dry, with a westerly wind. The operation was conducted behind my laboratory, in the neighbourhood of places not very clear, it is true, but from which the wind was blowing to all parts of the town. I did not observe any dust blowing, but if there were dust, it was such as we may be called on to breathe. The liquid was clouded, and the unaided eye could perceive that particles very light were floating. When examined by a microscope the scene was varied in very high degree—there was evidently organic life. I thought it better to carry the whole to Mr. Dancer and to leave him to do the rest, as my knowledge of microscopic forms is so trifling compared to his.

THE BOILER INSURANCE COMPANY.

WE have lately had occasion to notice the annual reports of the various companies which have been established for the inspection of steam boilers with a view to preventing explosions. How well they have succeeded in deserving the confidence of the public is evidenced by the immunity enjoyed by those who avail themselves of their assistance. We have taken these reports seriatim, in the order in which they were received by us, and we now come to that of Mr. Longridge, the engineer to the Boiler Insurance and Steam Power Company, Manchester. Mr. Longridge's report is carefully prepared, and extends to a considerable length, embodying a series of practical remarks which it would be well for every steam user to read and ponder upon. Mr. Longridge opens by admitting the explosion of one boiler under his inspection, and this is the second company which met with an accident during last year. However, in this instance—as in the previous one—no injury to life or limb was sustained. The report goes on to deal with defects, and the various causes which lead to accident. All these matters have been treated in previous notices, so that we need not again refer to them here. One point, however, which we have not previously touched upon should certainly have notice here, and that is, the difficulty of getting steam users to submit to a proper inspection. It may seem strange, but it is no less true, that, notwithstanding the numerous fatal explosions that have occurred, resulting from defects which could not have escaped the notice of a competent inspector, many of the users of steam power appear to be indifferent as to the condition of their boilers. They will rather incur the risk of an explosion than stop their works one day in the year that their boilers might be thoroughly examined. All seem to expect that any examination that may be required shall be made at one of the general annual holidays, when their works are necessarily idle. Even then many of them will not be at the trouble or expense of having the boilers properly cleaned and the flues swept, without which a satisfactory examination is impossible; but possibly in some cases this want of preparation may be the result of mere forgetfulness. As an example, we may refer to one instance where, by special appointment, an inspector was sent a distance of nearly one hundred miles, and as there were six boilers to be examined he proceeded thither the day before that appointed for the examination. Proceeding to the mill early on the following morning he found it closed, and no preparation whatever made. On seeing the owner he was requested to stay another day, but as this was impossible, on account of other engagements, orders were given forthwith to cool the boilers by running cold water into them, and to sweep the flues. This was accordingly done, but, it is scarcely necessary to add, the cleaning and subsequent examination were anything but satisfactory, and in consequence of the excessive heat in the flues, the inspector was very unwell for many days after. We cannot too strongly condemn this conduct, which is unfair to the company. Every facility should be afforded to their agents for making the inspection under fair conditions. If this is not done the company ought hardly to be held responsible for accident. Mr. Longridge's report is illustrated with five lithograph drawings from photographs of exploded boilers.

COLOUR OF SUN SPOTS.

MR. S. BROUGHTON recently informed the Literary and Philosophical Society that on observing with high powers a group of fine spots on the sun, one of which was of considerable magnitude, it occurred to him to remove the dark glass, and by keeping the eye much beyond the focus of the heating rays, and at such a distance that the spot almost filled the apparent field of the eye-piece, to see if any phenomena could be observed different from those seen through the dark glass. The spot was at once seen to be of a dark blood red; but, thinking this perhaps might be from the strong contrast of colour, he attached a disc of plaster of Paris to the telescope, and projected the image of the spot on it. On looking at this with a common pocket magnifier, the image was observed to be a dark blood red, although the observatory was not darkened, and the disc merely shielded from the direct rays by an intervening opaque substance. If these observations are confirmed, it will corroborate the opinion long held that the spots are not black, but appear so by contrast, and, as it would seem, from the intervention of the coloured glass.

Dr. Shortt is expected shortly to arrive here from India, bringing with him about a dozen and a-half of the walking fishes of India, Murrul and Korava, many of them intended as a present to the Zoological Society's Gardens from Dr. Day. The largest species, known as Ophiocephalus striatus, grow to upwards of 3ft. in length, and, if they succeed in England, will make a capital addition to our lakes and canals. The smaller variety, Ophiocephalus gachua, will perhaps be more interesting than useful, as they only grow to about 1ft. in length. Pains have been taken to accustom them by degrees to confinement before shipping them in tin boxes. Dr. Day is said to have come to the conclusion that they breathe air direct from the atmosphere, as well as air in solution in the water in which they live.

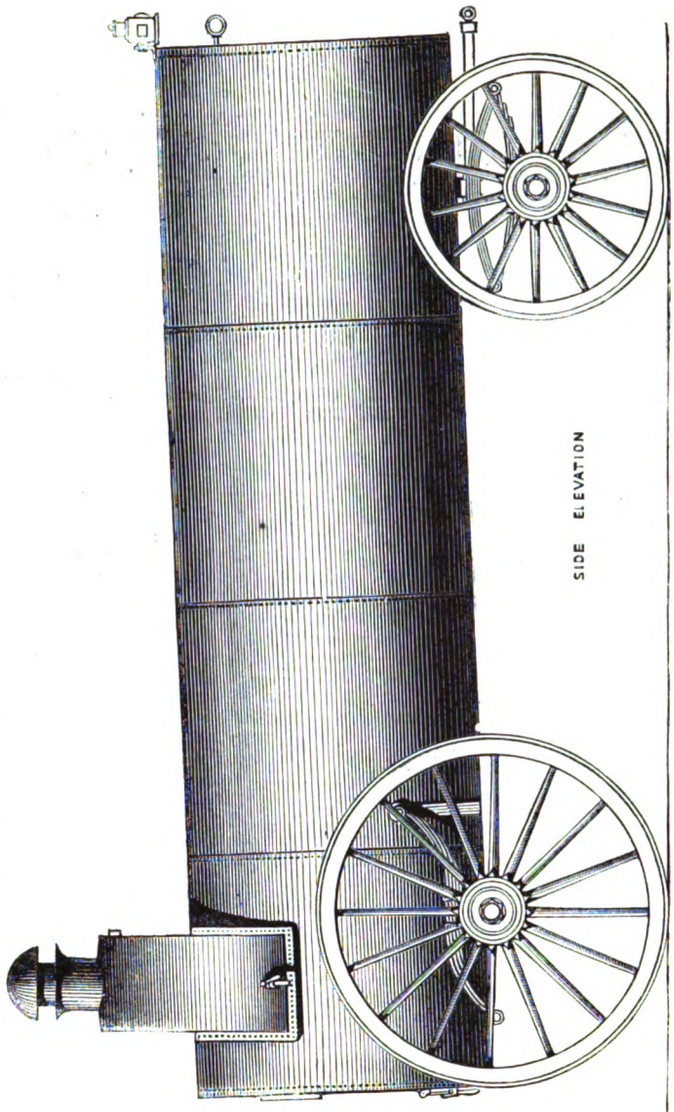
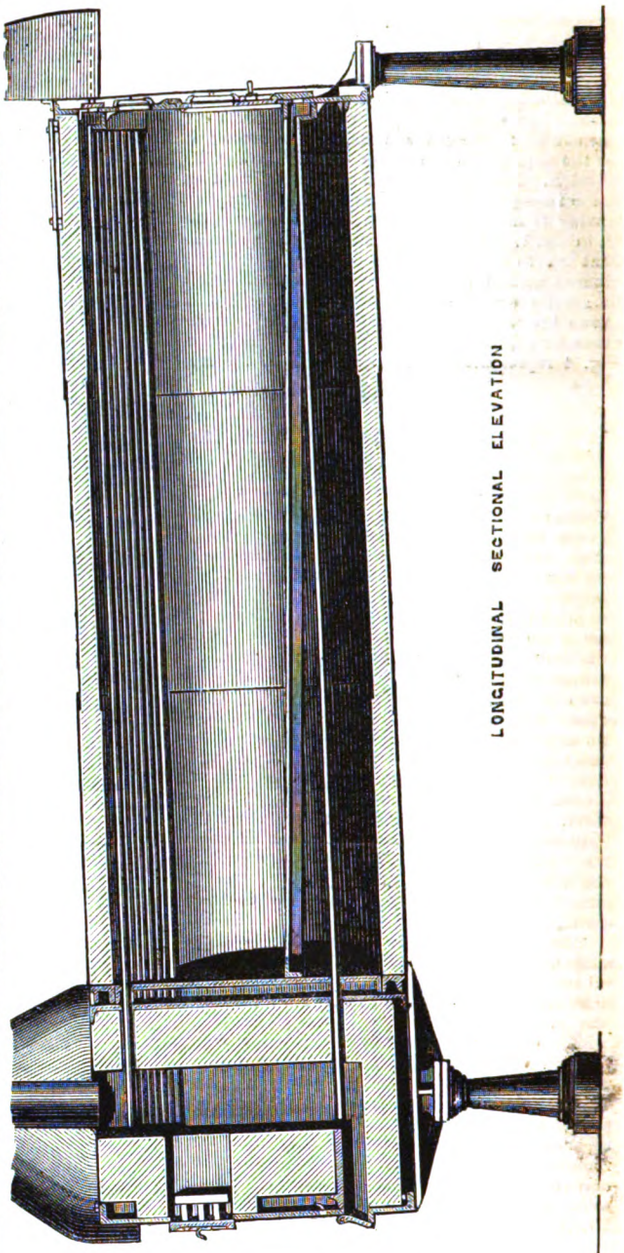
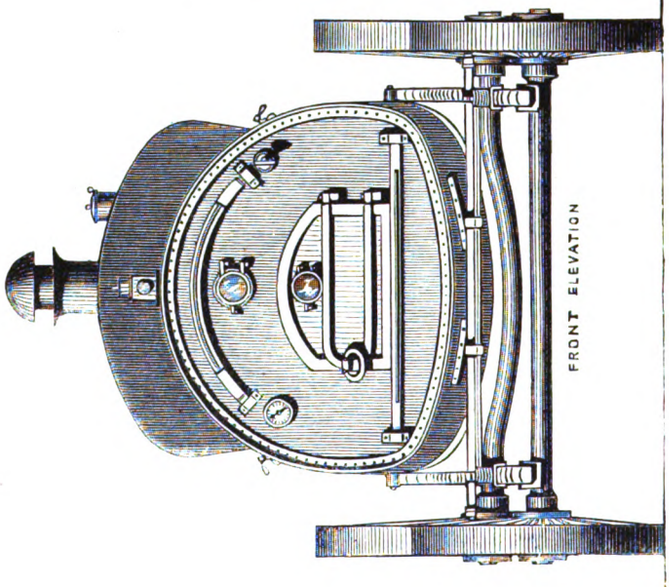
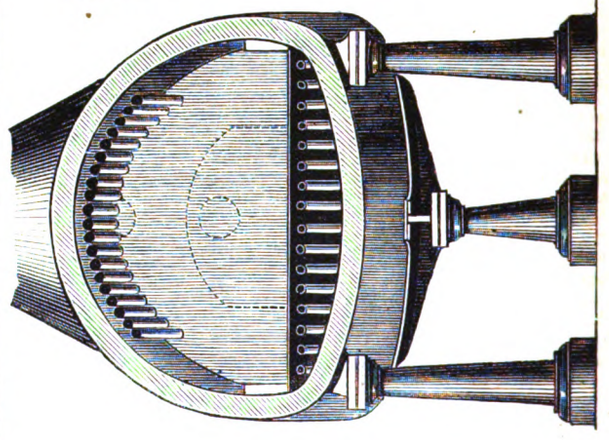
PORTABLE AND STATIONARY OVENS.

BY MR. A. M. PERKINS.









PORTABLE AND STATIONARY OVENS.

WE this week give engravings of the portable oven introduced by Mr. A. M. Perkins, as an improvement on the hot water ovens long manufactured by the well-known firm of which he is a member. These ovens have been approved and adopted by our own War Department, and since the exhibition of the oven in Paris last year, an important order for them has been given by a foreign government, and the attention of the French Commissariat Department has been directed to them by the Emperor himself. The mode of conveying heat from the fire into the body of the oven is decidedly original, and as the entire apparatus, as in the case of the portable, and the very similar stationary oven are of iron, their description will probably be interesting to others besides those for whose use they are more especially intended. The principal object of the inventor has been to dispense with the use of numerous joints which were necessary in the hot-water oven, and for this purpose he has substituted for the continuous circulation principle a set of simple butt-welded boiler tubes, each perfectly separate in its operation, and hermetically sealed at each end.

A carefully ascertained quantity of water is introduced into each of these tubes previous to closing it, and it is by the continuous evaporation of this water that the heat is transmitted from the fire to the oven. As will be seen in our engravings, the fire is made at one end of the oven in a

BY THE TERRE-NOIRE WORKS.

FIG. 1

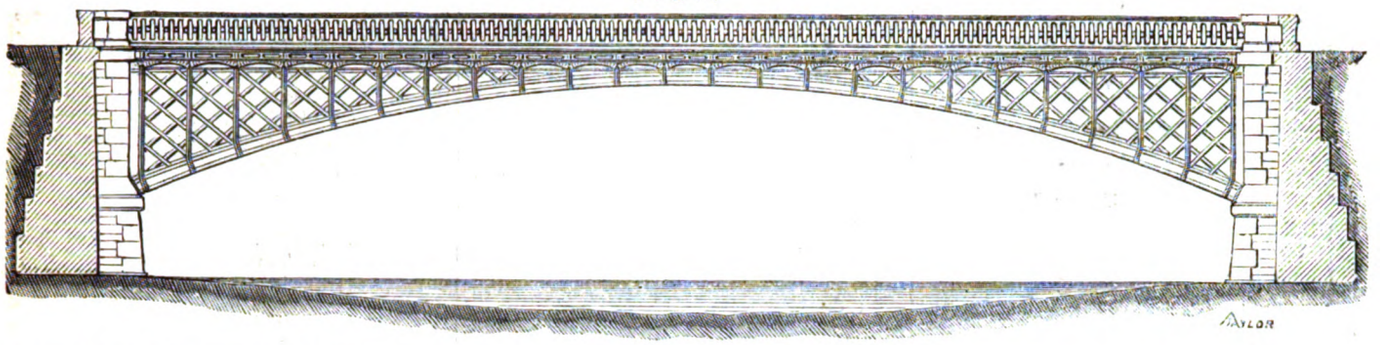

FIG. 2

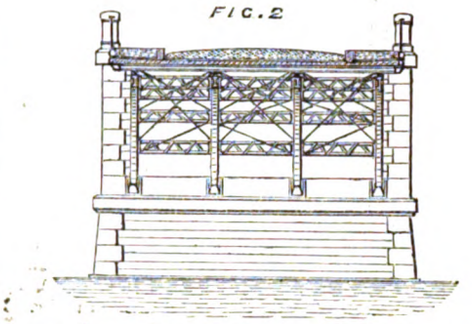

FIG. 3

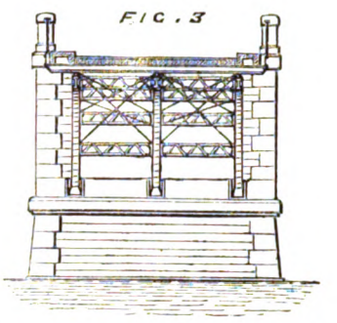


firebox of Stourbridge ware; the lower range of tubes passing under the bottom plate of the oven, have their ends projecting a few inches into the fireplace, and, in fact, form the firebars; the upper range have about an equal projection over the fire, and the smoke passes amongst them on its way to the chimney; both ranges of tubes are given a considerable slope towards the fire so as to provide for the return of the water, which is being continuously but very slowly condensed in the oven, as the steam imparts to it the heat it brings forward from the fire. The casing of the oven is double, the space between them being filled with non-conducting material. The stationary ovens are of cast iron, and peat or other substances are used for the non-conducting envelope, but in the case of the portable oven the double casing is of sheet iron, and the filling material is vegetable black, of which only 40lb. are required to fill the space of 3in. thick encircling the entire oven, and so completely intercepting the heat that when the temperature is 450deg. inside the outer surface of the oven is absolutely cold.

Our engravings show a side elevation of the portable oven and sections of the stationary one, which, however, in all essential particulars except the supporting pillars are also correct sections of the portable. The hood-like projection at the fire-door end of the portable oven is only a boiler placed around the chimney for the assistance of any other cooking operations in the camp. As may be supposed, the economy of fuel in these ovens is very great, the Deputy Commissariat-General, War Department, states that whilst the common oven for a given quantity of bread required 224lb. of coke to heat it, Mr. Perkins' oven only used 56lb. for the same quantity. Scarcely anything can be more conclusive of its economy.

USE OF STEEL IN BRIDGES.

SOME time ago, previously to the discovery of the numerous difficulties that attend the production of a reliable and homogeneous description of steel, it was confidently expected that it would supersede cast and wrought iron, in a manner similar to that in which those materials have been substituted for their ancient predecessor timber. These anticipations, it is needless to remark, have not yet been realized. Partly owing to the want of accurate information respecting the constructive qualities of the material, and partly to its high price, it has made little or no progress towards deposing ordinary iron from the position it holds. One insuperable drawback against its general adoption is the apathy displayed by the Board of Trade, and their entire unrecognition of its merits. So long as that great and inappealable authority continues to ignore its superior qualities, and refuses to make any alteration in its arbitrary rules with respect to metallic structures for railway purposes, so long will it be impossible for the engineer having regard to economy, to adopt it in his designs. If no greater strain than the stereotyped one of five tons per square inch is to be placed upon a material calculated upon the assumption of its minimum strength to be able to bear eight, then, since it is a more expensive article than the material competent only to bear that strain, its employment is at once doubly forbidden. Although we are, as usual with the Anglo-Saxon, in the background regarding any modern improvement and advancement, scientific or otherwise, yet, fortunately, other nations are neither so timid nor so lethargic, and the contents of the present article, together with the accompanying illustration, will convince our readers that the new material is receiving, at any rate, elsewhere, the attention it deserves.

Among the many interesting specimens of construction exhibited at the late "Exposition" was the steel bridge connecting the Quai d'Orsay across the passage which brought the Champ de Mars into communication with the Seine. It is the first work of a similar character built in France, and wherein Bessemer steel has been used as the principal component. Some years ago, the price of steel was so high that it would have been preposterous to have thought of applying it to bridge construction, but latterly the manufacture of that substance by the Bessemer process has placed in the hands of engineers and architects a new agent of construction. At the establishment of Terre-Noire this well-known process has been put into operation, and upon a large scale, in the manufacture of rails, plates, bars, and other special forms suitable for mechanical purposes. By the employment of certain ores, especially adapted for the process, and by the adoption of various precautions in its different steps, many of the difficulties hitherto attending its success have been overcome, and it is possible to produce steel, *a la* Bessemer, possessing different degrees of hardness and elasticity, according to the use it is intended for. When once this fact is clearly established, steel will no longer occupy the place of an unknown and untried material, but will take that position in the constructive arts it is indisputably entitled to. In comparing the steel manufactured at Terre-Noire with ordinary iron, there would be an economy of forty per cent. obtained by the use of the former, so far as the theoretical sections and weights were concerned. The saving, it must be borne in mind, has a double value, as it affects not merely the actual quantity used, but also diminishes the cost of transport. Having made these preliminary remarks, let us now turn our attention to the system adopted in our example, the conditions it fulfils, and the results that have been obtained from it. The bridge of the Quai d'Orsay is represented in fig. 1 in elevation, and in transverse section in figs. 2 and 3. It has a span of 82ft., and supports a paved roadway, the footpaths being formed of asphalte concrete with curbs of stones set on end. The ribs are of the solid or plate form, having a rise of 8¼ft., and the flanges are composed each of a pair of steel angle irons united to the web by steel rivets. Ordinary iron was employed in the cross girders and bracing shown in the transverse sections. By order of the authorities the following regulations had to be adhered to most stringently in the design and execution of the bridge. The roadway was to be formed of oaken blocks, 5in. in thickness, covered with metalling or paving 10in. in thickness, and the proof test for the ribs was to be at the rate of half a ton per square yard of surface of superstructure. For every square inch of sectional area of wrought iron, five tons was the limit permitted, and this was increased to seven for the steel ribs. During the testing of the bridge, the load was increased twenty-five per cent. above what had been prescribed, and allowed to remain upon it for three days, without, however, producing a deflection greater than 1¼in. Upon the removal of the testing load the ribs recovered, practically speaking, their original form evincing no permanent set beyond what is inevitable in all structures submitted to a heavy test. In addition to the action of a dead load, the bridge was subjected to that of a rolling one, consisting of two waggons loaded with stone and each drawn by five horses. One of these had but a single axle and weighed nearly twelve tons; the other weighed rather more, and was furnished with two axles. The two waggons were drawn over the bridge separately, together, in the same, and in contrary directions, and scarcely any deflection was appreciable at either the crown or haunches of the arch. This bridge resisted during the whole time of the Exposition a very heavy description of traffic, including the passage of some enormous cannons and other huge monuments of mechanical skill and industry. At the close of the Palace it was taken to pieces, and is destined to be reconstructed, as a bridge of three arches, at Port-de-Roche, Langon. That the use of steel in these instances allows of a diminution of dead weight there is no doubt, but at the same time its value must not be exaggerated. In all structures of this description, there are numerous component parts in which neither the weight nor sectional area can be reduced with safety, even by the employment of a lighter material, and, therefore, in these cases the adoption of steel would simply entail an increase of expenditure without any equivalent advantage. Until, therefore, Bessemer steel can be produced at a price nearly equal to that of iron, it will be necessary to reserve its use for those parts of a bridge, roof, or other structure, which are most severely strained, and in which the entire sectional area is susceptible of useful work. In girder bridges the thickness of the flanges would be lessened by the employment of steel instead of iron, and by so doing the riveting would be better accomplished. There is not so much advantage to be gained by the adoption of steel in cross

Digitized by Google

girders unless they are placed far apart, as in the main beams, but still, under certain conditions of loading, an economy will be effected by so doing. The absolute saving in the cost of transport, by the substitution of steel for iron, will depend upon the type of construction selected, but it may be considered as ranging from twelve to twenty-five per cent. In large roofs steel presents more advantage than for other examples of a similar nature, as the rolling load is reduced to zero, and no great insistent weight or vis inertiæ is required, provided that the roof be effectually braced against the violent and irregular action of the wind.

RECENT LAUNCHES.

THREE fine ships have recently left the stocks, two of which were ironclad, the other being unprotected. Taking them in the order of launching, the latter comes first. This is the screw sloop "Sirius," which was built at Portsmouth, from the designs of the Chief Constructor of the Navy, and was launched on Friday. She is one of the vessels built or building of the improved "Amazon" type. She measures between perpendiculars 212ft.; her length of keel for tonnage is 185ft. 8in.; her extreme breadth, 36ft.; her breadth for tonnage, 35ft. 10in.; her breadth moulded, 35ft. 2in.; and her depth in hold, 19ft. 4·75in.; her burden in tons, o.m., 1,268 8-94. Her machinery will consist of a pair of Maudslay, Sons, and Field's patent compound engines, of a nominal power of 350-horse, driving a Griffiths-Maudslay screw. The "Sirius" is a wood-built vessel with rolled iron deck beams, iron stringer plates under the upper deck at the water ways, and iron diagonal strap fastenings. She will carry no armour, in common with all others of her class. Her armament will consist of two 6½-ton 7-in. muzzle-loading rifled guns, mounted on iron carriages and slides, and two rifled and converted 64-pounders. The official estimate of the cost of the ship fitted for sea, but exclusive of machinery and armament, is £43,000.

The two remaining launches took place on Saturday; the first was that of the "Repulse," built at Woolwich. This ship is an ironclad of 3,734 tons burthen, and is pierced to carry twelve heavy guns. The third launch took place at the Thames Iron Shipbuilding Company's Works, of an ironclad of much larger dimensions, the "Konig Wilhelm," built for the Prussian Government at a cost of nearly £450,000. The ship was originally intended for the Turkish Government, who, failing in providing the necessary funds, the directors of the Thames Ironworks cancelled the agreement, and succeeded in persuading the Prussian Government to purchase her. Her principal dimensions are as follows:—Length between perpendiculars, 365ft.; length of keel for tonnage, 320ft.; breadth of tonnage, 60ft.; depth of hold amidships, 41ft.; engine power, 1,150-horse (manufactured by Messrs. Maudslay); tonnage, 6,127 tons. The ship came off the slips in magnificent style, decorated with the Prussian national colours.

INSTITUTION OF CIVIL ENGINEERS.

AT a meeting of the Institution of Civil Engineers, held April 21, 1868, Mr. C. H. Gregory, President, in the chair, a paper was read on irrigation in India, by Mr. Allan Wilson, M. Inst. C.E.

Having had fourteen years' experience in the construction and superintendence of irrigatfon works in the central and southern provinces of India, where wet cultivation was extensively practised, the author proposed in this communication mainly to refer to that part of the empire. A brief account was, in the first place, given of the former and present systems of irrigation, followed by a detailed description of the accessory works; and the cost of providing the water was then noticed.

The value of artificial means of irrigation, for increasing the fertility of the soil, was recognized in India at an early date. In the Punjaub, canals for this purpose, as well as for navigation, were constructed as far back as the middle of the fourteenth century. But it was in the southern parts of India, where the rainfall was more precarious, and the river supplies less easily available, that the most extensive works were to be found. It had been estimated that, prior to the establishment of British rule, there were, in fourteen of the principal irrigated districts of the Madras Presidency, upwards of 43,000 tanks and channels in repair, besides about 10,000 out of repair, having, probably, 30,000 miles of embankments, and 300,000 separate masonry works. Some of these tanks and reservoirs were on an immense scale, for irrigating many thousand acres, while there were smaller tanks, wells, and springs, which watered only a few acres. It was remarkable that the Government should have allowed so many fine works gradually to fall into decay, without replacing them by others; as great natural facilities existed for storing water, and for forming canals to lead it on to the land. The irrigation works on the Godavery and Kistna rivers, in the northern Circars, and on the Coleroon, in Tanjore, had only recently been completed; but many large rivers were still allowed to flow into the ocean, almost unused for agricultural purposes.

With regard to the most general and least expensive mode of irrigation by means of artificial reservoirs, and to the methods adopted in forming such reservoirs, it was stated that in selecting a site it was essential to ascertain, in the first place, that the foundation was suitable; the next point to be determined was the extent of land to be irrigated and the quantity of water necessary for such irrigation. The area of the drainage or gathering grounds could be estimated from the trigonometrical survey maps of India, and the quantity of water that would pass into the tank during floods should be calculated according to the known rainfall, due allowance being made for absorption and evaporation. With these data, the dimensions of the different works could be fixed. It should, however, be borne in mind, that depth of water was of greater importance than a large surface area, as the evaporation would be less in the former case. An examination should also be made of the valleys in the vicinity of the proposed reservoir, with a view to ascertain whether the surplus water flowing through the tank during floods could not be carried across intervening ridges, and be stored in natural basins at a small outlay, so as to fill a chain of tanks. It was explained that a tank was simply a reservoir formed by throwing an embankment, or bund as it was called in India, across a valley to dam up the drainage. The most simple description of bund was constructed entirely of earth, which was generally dug from the bed of the intended reservoir. The breadth at the top was usually about 12ft. The inner slope was three to one, and this was faced with a pitching of loose stone, while the slope of the land side varied from two to one to one to one. Puddle was seldom, if ever, used; indeed, it was not required, as, owing to the lodgment of silt, a tank would puddle itself as soon as it had been once filled. In illustration of this fact it was mentioned that Major-General Sir Arthur Cotton had stated that in a channel cut through loose sand, within a yard of the water's edge to a depth of 5ft., not the least moisture was found in the excavation, the lining of silt having rendered it completely water-tight. In addition to this embankment, some of the large Hindoo works had a massive retaining wall of masonry in front. Many of these walls were built of dressed stone, close-jointed, backed with rubble and a rough description of concrete; and flights of steps of cut stone were constructed down to the edge of the water.

To obviate the danger of an excessive influx of water during floods, most tanks were provided at one end, and not unfrequently at both ends, of the embankment, with a waste weir (known in India as a calingulah), to allow the surplus water to escape after the tank had been filled. In constructing a tank, the discharge capacity of the calingulah was an essential feature. It was a safe rule to allow one-fourth more than the dimensions obtained by calculation, so that the water might have a free passage in the event of an excessive flood, as otherwise the earthwork might be entirely destroyed.

The author had found that many of the tanks which were now useless had been breached from no other apparent cause than the want of sufficient outlet to carry off the surplus water during floods. In constructing these calingulahs, upright stones, varying from 2ft. to 5ft. in height, were fixed in the body of the masonry, at intervals of from 3ft. to 4ft. When the rains were moderate, as the monsoon was declining, these spaces were filled with brushwood, straw, earth, or rubbish, to prevent the further escape of water, and to store up as much as possible. This contrivance showed how highly water was appreciated by the natives of India; but unless the process of filling up was very gradual, and its completion deferred until the rains had entirely ceased, the results were often most disastrous. Many of the ruined tanks appeared to have been breached solely from the desire on the part of the cultivators to retain the utmost quantity of water. The forms and dimensions of the calingulahs must, of course, be regulated according to the capacity of the tank, the area of the gathering ground, the rainfall, liability of drought, and other local circumstances; so that it was not possible to lay down any general rule, having regard to the great differences of rainfall, &c., in the several districts of India.

In order to draw off the water for cultivating the fields, each tank was provided with one or more sluices, their size and number depending entirely upon the area of land to be irrigated. The sluice in general use in Southern India was exceedingly simple. It was merely a tunnel through the bank, built of brick, or rubble, either arched at the top or covered with flat stones, the floor being paved with flat-jointed flags, and the side walls lined with the same. The inner end or head of the sluice or tunnel was closed by stones, and the water was allowed to enter through one or more orifices, generally from 3in. to 5in. in diameter, cut in these covering stones. The flow of water through these orifices was regulated by means of conical plugs of wood, each of which, being attached to a long handle, could be withdrawn or inserted as required.

At the end of the sluice tunnel below the bank, a cistern was generally built, having its sides pierced with holes at different levels, to enable the water to be drawn off at various elevations. From this point the water was carried forward in open ducts of the requisite dimensions, in the sides of which subsidiary or distributing channels were cut, generally at the expense of the farmer, to lead the water on to the land to be irrigated. The mode of preparing land for wet cultivation was by laying it out in squares, rectangles, &c., each plot being separated from the rest by mud walls of sufficient height and thickness to prevent overflow or percolation. These squares or rectangles were kept level, and were as large as the nature of the ground would admit. When one was sufficiently flooded, the water was let off at the lower corner of the field into the next division, and so on until the whole area had been irrigated.

With a view of showing how favourable some parts of India were for forming reservoirs of large capacity, attention was directed to a design for a large artificial lake, which it was proposed to construct by damming up the gorge of a valley. This reservoir would be capable of storing sufficient water to irrigate 200,000 acres of land, an area equal to the county of Buckingham, allowing the usual average of 500 acres to the square mile as being under cultivation. Taking 170,000 acres as the extent of land to be irrigated for a single crop, this would require provision to be made for the discharge of 170,000 cubic yards of water per hour at each end of the tank; and discussion was invited as to the best description of sluice for discharging such a vast volume of water.

Another method of providing a supply of water for artificial irrigation was by damming up rivers by anicuts, or masonry dams (also called weirs). The sites for many of these had been so judiciously chosen by native engineers, that but little expense had been incurred in building them. They were generally formed of boulders and stones thrown promiscously together. The side next the water had the outline of a retaining wall with a slight batter, and was laid with some care. On the downstream side, two rows of stones composing the lower edge of the apron were carefully laid by hand, and the upper courses on both sides were similarly placed. A detailed description was given of some old anicuts across the river Toombuddra, as well as a modern one over the same stream; of an anicut across the Kistna river, near the town of Bizwarrah; and of temporary weirs, of rough stones, which were not now so generally used as they were formerly. These masonry dams were, when practicable, taken advantage of for forming means of communication from one bank of the river to another, by building a bridge on the top of the weir. These dams had sluices at each end, and if requisite at other parts, to be kept open at times, so as to prevent the lodgment of silt above the weir. A head sluice should also be constructed, to enable the water in the river during a flood to be shut off, and so prevent sand, &c., from entering the irrigating channel. These sluice openings were closed by wooden shutters consisting of teak-wood planks, a native system which had been found to answer so well that it had been adopted more or less by English engineers.

Great differences of opinion existed as to the cost of storing and distributing water for irrigation. Thus, in a report made by Colonel Dickens, in 1855, on the Shahabad district, the estimated cost of storing and supplying water from four different tanks, including the cost of the distributing channels, was 400, 352, 350, and 494 cubic yards per rupee respectively, or an average of 400 cubic yards per

Digitized by Google

rupee, giving a cost of 8 rupees 12 annas per acre irrigated with 3,500 cubic yards, a quantity which was amply sufficient to raise more than an average rice crop. Colonel Rundall stated the rates per acre in the Madras Presidency at 6 rupees and 8 rupees 3 annas, giving an average of 7 rupees 15 annas per acre as the cost of storing water; but it did not appear whether the expense of the engineering establishment and of the distributing channels was included in these rates. The author stated as the result of personal experience, that a few years ago, in the south of India at least, an extensive area in the immediate vicinity of the work could have been provided with irrigation works, including distributing channels, at a cost of 10 rupees (£1) for every 3,500 cubic yards. Owing to the increase that had of late years taken place in the rates of all kinds of labour, the cost would now propably amount to 15 rupees per acre irrigated.

Water was also raised from wells, banks of canals, and rivers, for irrigation purposes, by means of the Persian wheel, and pumps of all kinds, worked either by men or by bullock gin; the môt operated by bullocks, and the picottah by men being employed. From springs water was lifted by basket scoops worked by men. A minute account was given of these several methods, accompanied by a statement of the quantities and cost of water, as well as a comparative statement of the number of cubic feet raised 1ft. high per day of ten hours, raised by these different plans in various parts of India.

As to the relative value to Government of irrigated and dry cultivation, it was stated that, in the fourteen districts of the Madras Presidency already referred to, there were about two million acres of irrigated and twenty-five million acres of dry land, and that the revenue derived from the former was one and a-half million sterling, against barely two millions from the latter, so that the irrigated land yielded three times the revenue drawn from an equal surface of dry land. As regarded the gain to the cultivator from irrigated land independently of the certainty of reaping the crop, it might be stated that the average intrinsic or market value of crops raised on irrigated land was twenty rupees per acre, against six rupees for the produce from unirrigated land, or more than three-fold.

The great superiority of river and tank water for irrigation purposes, as compared with well and spring water, was next adverted to, as an additional argument in favour of the formation of river and tank reservoirs. In many localities, large profits might reasonably be expected to be realized, both from the construction of new works, and from additions and improvements to existing ones. Statistics regarding the extent of land at present irrigated were meagre, but it might be safely stated that not more than four million acres were watered by artificial works; and there appeared to be no prospect, in spite of the large remunerative results obtained therefrom, of an outlay commensurate with the requirements of the country being incurred by Government within any definite period. Judging from personal experience and observation, the author was of opinion that, considering the vast area requiring to be provided with these works, the comparatively small extent of the Government establishments, and the large capital that would be needed, the object could be best attained through the agency of private companies. This view would, he thought, be fully supported by a comparison of the operations of the railway companies with those of Government, in regard to irrigation works. The utmost sum that had been spent by the various governments and communities of India, on those primary and highly-remunerative works, was about four millions sterling, during a long course of years; whereas, no less than about seventy millions sterling had, within a few years, been spent by private companies on railways, which were far less remunerative, and might, moreover, be called subsidiary works, dependant for their full development and success upon the prosperity of the people. It was true that objections had been raised, and possibly not without reason, against the management of private companies; but the defects that existed were not inherent in their constitution, and might, the author believed, be obviated under suitable arrangements. Indeed, there was every inducement for a company to press on the construction of public works in the most rapid and efficient manner, so as to obtain a better return than the moderate rate of interest guaranteed by Government; and the realization of these advantages could not fail to attract capitalists. A feeling in favour of such companies was beginning to spring up among the natives of India, and this feeling would increase as the remunerative results of irrigation works became more apparent.

THE NEW ALABAMAS OF THE U. S. NAVY.

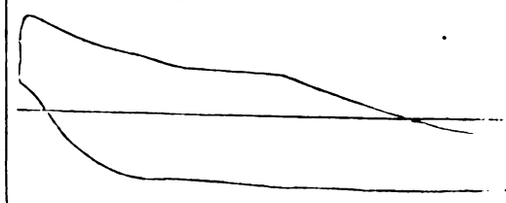
AT the time the last American war broke out the United States practically possessed no navy. Immense exertions were put forth by the Northern States to produce a fleet of fighting ships. Things were done in a hurry, and many mistakes were made. Since the war was brought to a termination much has been done at leisure to supply the country with an efficient fleet, and still graver mistakes have been committed. The first was excusable; the latter are not, and those who complain of the nepotism and prejudice which exist in official circles in England, may learn from the progress of events across the Atlantic that a republic is not necessarily exempt from the defects held by a class to be peculiar to our Imperial system of government. No Chief Constructor, no Board of Admiralty, no marine engineer in England has ever manifested the official incompetency displayed by the Bureau of Steam Engineering in the United States; and we cannot select a more interesting subject for a large class of our readers than the latest doings of Mr. Isherwood and his fellow officials in that department. Reports of their operations reach us tolerably regularly. These, it is fair to say, are often tinted, and sometimes highly coloured by prejudice. They require to be examined and sifted and compared carefully: but after every allowance is made which it is possible for an impartial observer to make, enough still remains to prove that the United States Bureau of Steam Engineering do not know how to design a good marine engine, and are thoroughly competent to commit blunders of sufficient magnitude to startle English marine engineers out of their propriety.

The United States navy is divided into two distinct classes, one intended for coast and harbour defence, and the weightier operations of warfare; the other to protect the commerce of the country. The first class consists of monitors, ironclad, and carrying 15-inch and 20-inch guns; the second of unarmoured cruisers, styled generally, "new Alabamas," which will act the part of a naval police. As regards the first class we are not nowabout to speak. The second claims all our attention. It is obvious that unarmed cruisers to be of use must possess great speed. They ought to be faster than the fastest blockade-runner if they are to be as efficient as it is possible to make them, so that they may be able to run away from ships of greater fighting powers on the one hand, and on the other to pursue and capture the fastest ships which a foe can employ in commerce. We have recently learned ourselves the value of such vessels, and the attempt has been made to supply England with them, it must be added, with but partial success; yet our Alabamas are immeasurably superior to anything which brother Jonathan has yet turned out or is likely to turn out while Mr. Isherwood remains in power.

The United States Alabamas will consist, first, of twenty ships with unpronounceable names, of which the largest will be 3,177 tons and the smallest 2,348 tons burthen; and secondly, of four vessels of greater size and speed called the "Wampanoag," "Neshamony," Pompanoosuc," and "Aminonusuc." These ships, if properly engined, would constitute a most formidable naval force. They have been built solely for speed on one of the sharpest and most beautiful models ever produced. They will be of wood and coppered. Their principal dimensions are—length on water-line, 335ft.; length over all, 345ft.; beam, 45ft.; depth in hold, 23ft.; mean draught, 18ft. 2in.; immersed mid-ship section, 720 square feet; displacement, 4,105 tons. It should be a comparatively easy matter to drive such ships as these at sixteen knots. Mr. Isherwood and the authorities proposed that they should have a sea-speed, in moderate weather, of fifteen knots. It may be easily shown, by calculation, that such a vessel could be propelled at the former speed by about 5,500-horse power, and at the latter speed by about 1,000-horse power less. As we are not in possession of drawings of the hull we hesitate to endorse the statement of American authorities, which is to the effect that the speed of fifteen knots could be obtained by 3,500-horse power. The truth probably lies between ours and the American estimate, and we prefer to adopt the larger measure in order to avoid any imputation of injustice as regards Mr. Isherwood. Up to the present moment only one of these large Alabamas, the "Wampanoag," has been tried at sea. It is stated that an average speed of 16·71 knots has been maintained for several hours consecutively, while a speed of 17·25 knots was kept up for some hours. But the report to this effect must be received with the utmost caution, as will be seen presently.

It is obvious that on the construction of the engines the success of such a craft as the "Wampanoag" must altogether depend. The model is so excellent that the engine builder cannot shift the responsibility from his own shoulders to those of the naval architect, and Mr. Isherwood's reputation must stand or fall by his machinery. Such machinery, we venture to state, never before was sent afloat; and before we proceed to indicate its character we feel it necessary to assure our readers that we exaggerate nothing, the accuracy of every statement being guaranteed by authority which may be regarded as indisputable.

The "Wampanoag's" machinery consists of two cylinders, each 100in. in diameter by 4ft. stroke. The pistons drive the screw shaft through the intervention of eighteen cogged wheels fixed, nine on the crank, and nine on the propeller shaft, and so proportioned that the screw makes two revolutions for one of the engines. The cog-wheels measure 13ft. over the face. The ship being of wood, it is certain that in a sea she must strain and change her shape. Precautions should, therefore, have been taken to prevent the twisting out of line of the bearings by using a bed-plate. Instead of this, the engines are bolted directly on the timbers, and, to make matters worse, the crank shaft, which is 40ft. long over all, is fitted with no fewer than four bearings, each 4ft. long, thus, including the crank pins, there is not less than 20ft. 8in. of bearing surface on the shaft. As a result, we need hardly say the consumption of lubricants must be prodigious, and, in a rough sea, the bearings cannot be kept cool at full speed. We shall not say one word as to the folly of using gearing at all. It is simply a thing at which English engineers laugh. They cannot condescend to argue about it. One result of its use is, that as the screw runs at but sixty revolutions, or thereabouts, per minute, the engines makes but thirty, and, consequently, the power of the 100in. cylinders of the "Wampanoag" is only equivalent to that of two 70in. cylinders with pistons running at the speed proper to the screw—that is to say, at 480ft., instead of 240ft., per minute. We shall come to the boilers presently, but, before speaking of them, it will be well to say something of the power of the engines. We give here a diagram



for which we are indebted to the "Army and Navy Journal of New York," which diagram may be regarded as perfectly authentic. It was taken when the engines were at little over half-speed—eighteen revolutions—with the throttle valve a quarter open, and the link in full gear. The steam pressure in the boiler was 27·5lb., and the vacuum in the condenser 20in.! Nothing can well be much worse, the compression being excessive, although the ports are 40 per cent. larger in area than any English engineer allows. The engines are fitted with a Sewell surface condenser, which, with the engines at half speed, and the temperature of the sea 32deg. Fah., gives, as we have said, 20in. of vacuum only. This wretched result is due to the fact that the circulating pumps are too small, and is magnified at higher speeds, because the weight of steam passed through the cylinders increases in a more rapid ratio than the speed, while the weight of condensing water varies directly as the speed. Under these circumstances, it would be wrong to assume a greater effective average pressure in the cylinders than 20lb. per inch, the average boiler pressure being 32lb.—probably, this is over the mark a good deal. Now, at the time the "Wampanoag" was said to have attained 16·71 knots, the engines made, we are told, but thirty-one revolutions per minute. This is equivalent to a piston speed of 248ft. per min. The area of a 100in. piston is 7,854 square inches; multiplying this by the speed in feet per minute, and dividing by 33,000, we get 59-horse power, nearly, as the power of one engine per pound of average cylinder pressure, or, for two cylinders, 118-horse power, or for 20lb. 2,360-horse power only. We have seen that, on the lowest estimate, about twice this power would be required to propel the ship at 16 knots, and we are therefore forced to the conclusion that, if such a speed was ever attained, the screw must have run off over 120 revolutions per minute, or the cylinder pressure must have averaged 40lb. throughout the stroke, while the vacuum was but 18in. or 19in. of mercury. We leave our readers to choose their own alternative; for ourselves, we state plainly that we do not believe that a speed of 16 knots was, if attained at all, ever maintained for more than a minute or two, unless, indeed, which is not unlikely, she was running before a strong wind in a powerful tide race.

We now come to the most extraordinary features in Mr. Isherwood's abnormal designs. We think it is plain that under no circumstances can the engines of the "Wampanoag" develope more than 3,500-horse power. What boiler power do our readers suppose has been provided to supply a pair of 100in. cylinders at thirty revolutions? The reply cannot fail to startle them. The "Wampanoag" is fitted with no fewer than twelve boilers, containing fifty-four furnaces, affording 30,000 square

Digitized by Google

feet of heating surface, and 1,130ft. of grate surface, and weighing, with their fixtures, over 400 tons. Boilers and engines together occupy a space of 175ft. in the length of the ship, and owing to her small beam there is little or no space in the boiler-room for coals, which are carried, therefore, in bunkers on the berth deck!! In fact, with the exception of a few storerooms aft and a little space forwards, the entire orlop deck is occupied by machinery. As a climax to the whole, the engines of this new "Alabama" are at least 70 per cent. heavier than the heaviest engines of equal power used by any other nation, while an idea of her capacity for sailing may be formed when we state that she has four funnels, each about 7ft. in diameter, so profusely stayed that an awning cannot be put up without taking down some of the guys.

In order to fully realize the nature of the enormous blunder committed by Mr. Isherwood, we shall compare the engines of the "Wampanoag" with those of the "Lord Warden" ironclad and the "Orlando," an unarmoured frigate not very unlike the United States ship. The "Lord Warden" engines have worked up to 6,700-horse power. The boilers have but 700ft. of grate surface and 13,000ft. of heating surface to supply three cylinders 92in. diameter, 4ft. 6in. stroke, running over sixty revolutions per minute. The "Orlando," engined by Penn, has two cylinders, with an effective diameter of 92in. and 4ft. stroke; she has eight boilers and thirty-two furnaces, and a grate surface of but 688ft. Total length of space occupied by machinery and boilers, 90ft.; indicated power of engines, 3,992; the total weight of propelling apparatus, including the water in the boilers, being but 648 tons. The engines of the "Wampanoag," without the propeller, but including its shaft, weigh 400 tons, while the whole weight of the propelling apparatus, including water in boilers, is about 1,200 tons.

We need say little more. Mr. Isherwood has sacrificed every necessary quality in a sea-going ship, and has sent a cargo of machinery of the most inefficient description afloat. While he is at the head of the Steam Bureau English engineers need not fear competition; the English public need not dread the action of the United States as regards the production of a fleet of Alabamas. We have said nothing regarding the other twenty-three ships of the new Alabama class. They manifest nearly the same faults of design. Only one thing is more remarkable than these modern innovations in marine engineering; that is, that they should be suffered by an intelligent nation keenly alive to the value of naval supremacy to have any existence.—"The Engineer."

AERONAUTICS AT THE CRYSTAL PALACE.

THE programme of the new season, just published, gives notice of an aeronautical exhibition to be held in June, which may be expected to excite much interest. The exhibits will include,—light engines and machinery, working aerial apparatus and models, plans and illustrative drawings, kites for use in shipwrecks, or other nautical purposes, and for traction, landscape and cloud scenery as observed from a balloon, and other articles and objects connected with aerostation. A captive balloon will be employed during the exhibition for meteorological and other experimental ascents. During the new season, which commences to-day, numerous novel attractions are promised, which are likely to increase greatly the number of visitors, and especially of season ticket holders, whose privileges are extended in some important particulars. The fine library and reading room in the north-west gallery is now completed, and in full use. The free lectures, we notice, are to be continued.

THE WILSON FURNACE.

A MEETING of the members of the Cleveland Institution of Engineers was held on Thursday week, in the Corporation Hall, Middlesbrough. Mr. David Joy occupied the chair. Mr. Thomas Whitwell read a paper on the Wilson furnace, of which the following is an abstract:—In opening, the writer stated that he proposed to bring under the notice of the institution one of the most important sources of practical economy in iron making that had come under his notice. In a previous paper read before the institution, the subject of 2s. 6d. per ton being saved to iron manufacturers was brought before them, but unfortunately that was dependant on Acts of Parliament, railway opposition, &c. He now proposed to save 2s. 6d. per ton certain, and was doing it without waiting for permission of any one. In the present day, in the fight for the foremost place, they found a most important means of economy in the true utilization of heat, with the least possible waste known as regeneration. The mechanical engineer designed his boiler so that the greatest amount of heat might be taken up by the heating surfaces ere it passed the damper, the most perfect example being perhaps the locomotive, where the heat in the smoke-box, after passing through the tubes, was lower than in almost any other form of boiler, so low, indeed, that the waste steam in the blast pipe was necessary to maintain a draught. The Cornish tubular boiler was also a well known economizer of fuel. If, then, from the economy of the steam engine, they turned to the ordinary methods of making iron by puddling and heating, they found in one great point at least the most shameful waste of power to be met with in almost any scientific operation. They here saw coal burnt or destroyed with the most shameless prodigality, dense volumes of carbon being forced up the chimney, while the residue of the coal was shot into the ashpit in a half-consumed and almost raw condition. Should the engineer try to make any alteration, he was at once informed that the best iron had ever been thus made; that if they spoiled their iron it far counterbalanced any saving in coal; that the puddling furnace was so perfect and withal so mysterious a thing that the least alteration might throw it wrong, &c.; and hence puddling had been what it was for years, the prejudices of puddlers and managers being ever against meddling with the present perfect state of things, and hence no patent puddling furnaces had hitherto got forward.

Mr. Whitwell proceeded to give an interesting description of the furnace, patented by Mr. E. B. Wilson. This invention related to the construction and working of furnaces or fireplaces, in such a manner that when fresh fuel was supplied as usual, on the top of the fuel already ignited, the gases generated therefrom were made to pass downwards through the hot fuel, in lieu, as heretofore, of ascending through the fresh fuel, and air was also supplied at such points and in such quantity as might be suitable for complete combustion. He next explained the *modus operandi* of one of the earlier furnaces at work in Glasgow, where the coal entered at the top and the air passed through the coal to support combustion. Diagrams showing the principle of the Wilson furnace were next explained by Mr. Whitwell, who proceeded to remark in reference thereto, that during the introduction of this invention a series of battles had to be fought with the puddlers. The time was unfortunate, puddling was 10s. 6d. to 11s. 6d. per ton, and new things, both from the apathy of masters and the opposition of the men had very little chance of succeeding. This was the case here. The men struck first against the furnace itself; a fresh strike arose against the underhand having to fill the hopper, which was some 8ft. from the ground; a third strike was made against the men going into the ashpit to rake out the clinker once a day; and a fourth strike arose from the men asserting that the masters saved 10s. a ton by the furnaces, and that they would not work the furnaces unless the masters gave them 5s. per ton on puddled bars extra, as it was not fair that the masters should have all the profit. Was it to be wondered that a furnace made so little way against such determined opposition, or that the masters should give up the improvement in disgust.

Statistical results of the operation of a similar furnace adopted by the Bolton Steel and Iron Company for the Lancashire coal were next given by the speaker, who thereafter went on to describe the Wilson furnaces, as they were in operation at the Thornaby Ironworks. Relative to the latter, he remarked that on account of the Durham coal having the quality of coking, and being more bituminous than those of other districts, it was found that the conditions were wholly dissimilar. The experiments carried out in order to arrive at a proper result were next commented on, and after giving a detailed account of the mechanism of the furnace, which he was enabled to render more intelligible by a series of diagrams suspended on the walls, Mr. Whitwell stated that all points were provided for in this furnace. The gases only took up enough air to burn them properly; the action of the damper secured the yield, whilst the large generator provided a constant supply of gas; at the same time no other furnace would work with the damper in the same position, owing to the difference in the size of the firegrate and damper. The advantages of this furnace he declared to be—1st. It would make more puddled bar out of a given quantity of metal than any other furnace. 2nd. It would under proper treatment consume all its own smoke. 3rd. It would, owing to its conditions, make a better and more regular quality than other furnaces, as it never burned the iron, and never worked "rash." 4th. It would not use more fettling than an ordinary furnace. And 5th. It would not cost more per ton of iron than other furnaces in repairs, as a less quantity of fuel being burnt there was less cutting action on the brick-work. Having given returns to show that at Thornaby Ironworks the furnaces worked successfully—fifteen tons of puddled bars being manufactured per week of fifty-nine heats at 17½ cwt. of rough small coals per ton, Mr. Whitwell went on to describe another form of iron furnace now working at Thornaby Ironworks, which promised to exceed the results arrived at by the one he had already commented upon. This last system of furnace was applied in Lancashire, not only to puddling bar and heating furnaces, but to boilers and furnaces at chemical works for making soda-ash. It was applicable to all purposes where great heat was desired, whilst in first cost and economy of fuel it had no equal.

Legal Intelligence.

ADMIRALTY COURT.

April 24.

(Before the Right Hon. Sir R. J. PHILLIMORE.)

THE "LION."—JUDGMENT.

THIS was a cause of damage. The "York Town," an American ship, on December 8, 1867, left the London Docks on her voyage to New York in tow of two tugs, and when rounding Blackwall Point her starboard quarter was run into by the screw steamship "Lion," and sustained considerable damage.

The Solicitor-General and Mr. C. P. Butt appeared for the plaintiffs; and Mr. Milward and Mr. E. C. Clarkson for the defendants.

The defendants admitted the damage, and pleaded that the "Lion" was a passenger ship, bound from London for Hull, having two passengers on board, and being at the time of the collision in charge of a duly licensed pilot. That the employment of such pilot was compulsory by law upon the owners of the "Lion"; that the orders of the pilot were promptly and implicitly obeyed; that collision, if it was caused by the "Lion," or any one on board of her, was solely caused by the pilot, and that neither the "Lion" nor her owners were liable in respect thereof.

The cause was argued in March, and the Court, having taken time to consider the question of compulsory pilotage, now delivered judgment. The pilot, in his evidence, said there were no passengers on board, but it appeared that the master's wife and father-in law were on board, and the master said he treated them as passengers; but it appeared that they did not pay anything for their board; no receipt was produced of the payment of fare by them, and nothing was said about such payment until the "Lion" arrived at Hull. The master said he did not know that the carrying of passengers imposed upon him the necessity for compulsory pilotage, and yet that was the defence set up. The common law makes the *status* of passengers dependent upon the payment of a fare. The evidence with regard to the payment of fares by the captain's wife and father-in-law was so contradictory that the Court could come to no other conclusion than that nothing was said about the fares until after the collision. From the moment of the collision the "York Town" had a lien on the "Lion," and no subsequent act could remove it. The Court must, therefore, pronounce for the damage, and that the owners of the "Lion" were not exempt in consequence of a pilot being on board under the circumstances. Decree accordingly.

Correspondence.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Will you, or some of your readers, favour me with answers to the following questions:—1. Is the peroxide of manganese battery likely to prove superior to Daniell's battery in electro-plating, gilding, and casting?

2. Would a metal rod extending to nearly the bottom of the porous cell, or metal turnings with a shorter rod of the same metal, answer instead of the carbon? And, if so, what metal or metals would be a good substitute for the carbon in M. Leclanche's battery?

3. Why has M. Leclanche chosen zinc as the negative element?—I am, Sir, yours, &c.,

J. H. WILLIAMSON.

95, Cross-lane, Salford, Manchester.

April 23, 1868.

Digitized by Google

[The peroxide of manganese battery in its present form is not likely to supersede Daniell's battery for plating, gilding, and electro-casting. For durability and constancy Daniell's is unrivalled. For plating and electro-casting on a large scale, perhaps Wolaston's is the best. It is the form of battery that Messrs. Elkington use, and for gilding they use Smee's. At the present moment we cannot call to mind the exact arrangement of M. Leclanche's battery; but whatever that arrangement may be, in a carbon-zinc pair, zinc can never be the negative element. If the carbon-fluid be nitric acid, platinum only can be substituted; if nitro-hydrochloric acid, silver.—ED. M. M.]

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

ERRATA.—The cork cutting machine, illustrated at page 297 of our issue for the 17th ult., is by Mr. Dudley, and not Mr. Drummond, as by a typographical error it is made to appear.

MESSRS. SNOW and Co., BOSTON, U.S.—We thank you for your letter; a description of the new process of manufacture of oil of vitriol, to which you refer, will shortly appear in our pages.

RECEIVED.—W. R.—H. C.—S. G. C.—F. J.—I. H. W.—A. B. B.—W. H. H.—T. M.—C. W.—R. D.—J. S.—R. P.—Messrs. A. W. and Co.—H. D. R.—J. M.—E. J. B.—R. S.—Messrs T. and C.—A. A.—G. W. H.—S. R.—W. T. C.—R. Meetings for the Week.

MON.—Royal United Service Institution.—James Mackay, Esq., on "The Mackay Gun and Projectiles," at 8.30 p.m. Commander P. H. Colomb, R.N., and Captain Bolton, will exhibit their new signal lights.

Society of Engineers.—M. de Merritens on "The Marseilles Docks," at 7.30 p.m.

Royal Institution.—General Monthly Meeting, at 2 p.m.

TUES.—The Institution of Civil Engineers.—Continued discussion on "Irrigation in India and in Spain," at 8 p.m.

Royal Institution.—Dr. M. Foster on "The Development of Animals," at 3 p.m.

THURS. — Royal Institution. — Professor Bain on "Popular Errors," at 3 p.m.

Royal United Service Institution.—The adjourned discussion on Major Leahy's and Major Bevan-Edwards' papers on "Army Organization," at 8.30 p.m.

FRI.—Royal Institution.—Mr. C. Greville Williams on "The Artificial Formation of Organic Bodies," at 8 p.m.

Royal United Service Institution.—Hyde Clarke, D.C.L., on "The Military Value of a Continuous Railway Communication between England and India," at 3 p.m.

SAT.—Royal Institution.—Professor Bain on "Popular Errors," at 3 p.m.

Naval, Military, and Gunnery Items.

THE "Diana," 42, in Chatham harbour, is ordered to be brought forward for service in the Tyne, where she is to be stationed for the purposes of a training ship at the Tyne ports.

THE "Wellesley," 72, until recently the flag ship in Chatham harbour, has been removed round to the Thames, there to be stationed as a receiving ship for the training of homeless and destitute boys for the Royal navy and mercantile marine.

IT is stated that the protracted question of the terms on which the Spanish Government is to deliver up the "Tornado" has at length been amicably adjusted. The exact conditions of the surrender have not transpired.

AS an earnest of the honours which await the successful exploit of Sir R. Napier in Abyssinia, her Majesty has given orders that the gallant general (who is already a K.C.B.), shall be promoted to the military division of the first class of the Order of the Bath, or a Knight Grand Cross.

GREAT preparations are being made in Prussia for naval manœuvres, which are to take place in the course of the summer. For that purpose a considerable number of ships of war will be brought together in the Baltic, under the command of Rear-Admiral Kuhn.

IT is reported that a grand naval display will be made off Cherbourg, in the presence of the Emperor Napoleon, about the 19th inst., and that the British Channel fleet, under the commander of Rear-Admiral J. Warden, C.B., will be present in Cherbourg roads to do honour to the occasion.

BY a return issued on Saturday it appears that the actual strength of the naval reserve on the last day of 1867 was 15,091 enrolled members. During the year 12,890 men presented themselves for drill, 929 were absent with leave, 674 from unknown causes, and 528 were discharged, abroad, deserted, &c.

A NEW port has just been opened in the Adriatic—that of Monopoli, a very populous and wealthy town in the province of Bari. The ecclesiastical authorities took part in the inauguration by blessing the first stone. In commemoration of the time at which this ceremony has occurred, the name of Princess Margherita has been given by the municipality to the port.

IN consequence of the death of the Duke de Valencia, there remain only four marshals in the Spanish Army, namely, the Duke de la Vittoria, the Marquis de Duero, the Duke de la Torre, and Count de Cheste. The most ancient lieutenants-general are Baron de Meer, the Dukes de Bailen, Rivero, Sanz, Iriarte, Sora, and the Marquises de Novaliches, de la Havane, and de Maestrazzo.

THE "Journal du Havre" says:—The American ship "Mercury," known as the fastest sailer that visits this port, has just accomplished the quickest passage ever made by a sailing vessel between America and Europe. She left New York on the evening of April 9, and arrived at Havre on the morning of the 22d, the passage thus occupying some hours over twelve days. The quickest generally extend to sixteen days.

OUR leading ship-builders, engineers, and others, are likely to be well represented at the Havre Maritime Exhibition. Messrs. R. Napier and Sons, of Glasgow, who carried off the Grand Prix at Paris last year, are again exhibitors. Messrs. Randolph and Elder, who have a dozen new vessels nearly completed in their extensive building-yards on the Clyde; Messrs. Gourlay Brothers, of Dundee; Mr. James Laing, of Sunderland; Palmer's Shipbuilding and Iron Company, Jarrow; Mr. G. Farrans, North Shields; Messrs. Earl and Brownlow, and Lumsden and Co., of Hull, send models; whilst anchors, chains, cables, ropes, sail-making, fishing tackle, preserved provisions, and other industries, will have numerous exhibitors.

WE have to record the death of Lieutenant-General Geo. Jno. Belson, of the Royal Artillery, which occurred at Woolwich on Wednesday week, at the age of eighty years. The gallant officer entered the army as ensign September 29, 1804, and served in the Peninsular and south of France from July, 1809, to the end of the war in 1814, including the retreat from Talavera, the action in front of Almeida, and the action of the Coa. He was present at the battle of Busaco, the actions at Pompal, Redinha, Cazel Fova, Foz d'Arouce, and Sabugal; took part in the battle of Fuentes d'Onor, actions on the heights of the Agueda; also the sieges of Ciudad Rodrigo and Badajoz, and the actions at Castrajon (where he was severely wounded), San Munos, San Milan, and Osma. He was also present at the battle of Vittoria, and the action with the French, June 28, 1813, in the morning before they entered Pampeluna, when he captured their last gun from Vittoria. He took part in the actions in the Pyrenees, also the passage of the Nivelle, Nive and Gave, d'Oleron, and the battle of Orhes, besides various minor affairs and skirmishes.

Miscellanea.

THE annual dinner of the Institution of Civil Engineers is to be held at Willis's Rooms on Wednesday next, May 6, when the chair will be occupied by Mr. Charles Hutton Gregory, the president.

THE Right Hon. Benjamin Disraeli is announced to take the chair at the anniversary festival of the Royal Literary Fund, which will take place on May 6, in the New Hall, Freemasons' Tavern.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending April 25, was 3,392; total number since the opening of the museum, free daily (May 12, 1858), 1,289,978.

IT is stated that MM. de Dorlodot, of Acoz, have secured a contract for 25,000 tons of rails for the Helsingfors and St. Petersburg Railway, the contract price being £6 17s. 6d. per ton, and that a small contract for rails has been concluded in the Moselle district at £7 8s. per ton.

IT is stated that goldfields of great richnees exist between the Zambesi and the Transvaal in the Mekonos county. These fields are described as only sixty miles in length and twenty in breadth. From specimens which have been obtained from the quartz it is considered that the yield of gold will exceed the Australian and Californian averages.

WE understand that Mr. E. J. Reed (Chief Constructor of the Navy) has consented to read a paper before the members of the London Association of Foremen Engineers to-morrow, April 2, at 8.30 p.m. Subject: the means of testing iron. Mr. Newton, of the Mint, will preside, the place of meeting being the George Hotel, Aldermanbury, City.

AT three o'clock this afternoon a trial run is to be made from Charing-cross to the Bank with an improved omnibus which has been invented by Mr. W. Harvey. We certainly want some improvement in these vehicles, and as the Omnibus Company did their best to throw out the Tramways Bill, we trust they will be made to give the public decent vehicles to ride in.

PRINCE NAPOLEON, who, not long since, presented a very fine collection of gold Ottoman coins to the Bibliotheque Imperiale of Paris, has now given to the same establishment a collection of American bank-notes, consisting of seventy-five specimens of various kinds, and twenty-five proofs on India paper of engraved portraits and vignettes employed in the ornamentation of these notes.

THE "Kingston (Jamaica) Morning Journal" of March 26 says:—The Government received by last packet, from the royal gardens at Kew, a case of healthy tea plants, which are to be sent to the Chinchona Nursery in St. Andrew, and placed under the care of Mr. Thompson, the island botanist. The idea has been formed, we believe, on good scientific authority, that our soil and climate are so well adapted that the tea plant will flourish here.

A TERRIFIC thunder storm broke over North Lincolnshire on Monday, doing immense damage to the large orchards between Barton and Grimsby. At East Halton the lightning struck a young man named Elm, employed by Mr. Slight, miller. The unfortunate youth, who was only twenty years of age, was attending to the brake of the mill when the electric fluid struck him on the face under the left ear. Death was immediate.

THE visitors to the South Kensington Museum during the week ending April 25, 1868, were—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 10,322; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 2,037. National Portrait Exhibition, by payment, 2,712; Total—15,071. Average of corresponding week in former years, 11,188; total from the opening of the museum, 7,344,945.

BY last mail from India it is announced that the iron girder work of the Beas Bridge on the Delhi Railway for the first span was hoisted into place on the 25th of March, in the presence of Sir Donald M'Leod, lieutenant governor of the Punjaub, his staff, and the chief officers of the railway. This intelligence is highly satisfactory, as the engineering difficulties which had to be overcome in constructing the foundations of this bridge were very considerable.

FROM the report of the Zoological Society it appears that the balance-sheet shows receipts during the past year to the amount of £25,000, of which sum so much as £12,000 is from admissions to the gardens and over £6,000 from subscribers—a very large proportion for the sake of securing a Sunday promenade. The receipts for 1867 exhibit a considerable increase over those of the previous year, which is the more satisfactory as most institutions have had to suffer a falling off.

A SAD accident occurred at Chicago on Good Friday. The Roman Catholic Cathedral of St. Mary was filled with worshippers and the weight of the multitude caused a portion of the floor to give way, which raising a great dust led some one to cry "fire." A terrible panic ensued, and in the rush that was made for the doors four women were crushed to death, and twenty or more persons were seriously injured, three of them having since died.

AN Industrial and Fine Arts Institution, intended solely for instruction in science and art, was opened on Tuesday at Wakefield, The inaugural meeting took place in the evening, and was addressed by Mr. W. H. Leatham, M.P., Mr. Mundella, of Nottingham, and Mr. Cole and Mr. Redgrave, of the South Kensington Museum. The Institution has been formed out of a surplus of £3,000 obtained from an exhibition held in Wakefield three years ago.

A MEETING of the fellows of the Royal Botanic Society, Regent's Park, was held on Saturday, C. R. Turner, Esq., in the chair. The names of the following candidates for the fellowship were read:—Earl of Sefton, H. G. Sturt, Esq., M.P., Mrs. Hyam, Lieut.-Colonel Robert Unwin, H. F. Underwood, Esq., Mrs. Alcock, Peter H. Berthon, Esq., Richard Hodson, Esq., Mrs. James Lyall, H. H. Robertson

Aikman, Esq., Mrs. J. Gerstenberg, Mrs. Morrison, Rev. Henry Smith, J. E. Taylor, Esq., Mrs. Drake, Le Commandeur J. de Selles, in addition to eight elected on the same day.

WE take pleasure in announcing that the captain and crew of the "Rob Roy" yawl (J. Macgregor, Esq.), will "make a voyage alone" from the log of the above vessel at St. George's Hall, Langham-place, on Thursday evening, the 7th inst. Apart from the interest of the voyage, we are sure that the narrator will not be "alone," as the proceeds are to be devoted to the benevolent purpose of building the shoeblacks of London a new house, a step rendered necessary by the demolition of their old one for the Law Courts. The Earl of Shaftesbury will preside. Tickets at 24, New-street, Spring-gardens.

ON the evening of April 9, the advocates of an international copyright held a meeting in New York, and formed an association to support the project and urge it upon the attention of Congress. William Cullen Bryant presided. It appears that in 1853, Edward Everett, then Secretary of State, negotiated an International Copyright Treaty with John F. Crampton, then the British Minister, providing that any citizen of either country obtaining a copyright should by that Act obtain a copyright in the other country. This treaty was never ratified by the United States' Senate, however, and lost its vitality twelve months after negotiation.

BY the Clerkenwell outrage six persons were killed outright, six more died from its effects, according to the coroner's inquests, five, in addition, owe their deaths indirectly to this means, one young woman is in a madhouse, forty mothers were prematurely confined, and twenty of their babes died from the effects of the explosion on the women; others of the children are dwarfed and unhealthy. One mother is now a raving maniac; 120 persons were wounded; fifty went into St. Bartholomew's, Gray's-inn-lane, and King's College Hospitals; fifteen are permanently injured, with loss of eyes, legs, arms, &c.; besides £20,000 worth of damage to person and property.

THE "British Medical Journal," continuing its reports on the Preventible Diseases of the Industrial Classes, says that workers among dust are either so ignorant of the dangers to which they are exposed by inhaling dust for a long period, or so careless of their health, and so regardless of all warnings, that measures are seldom taken to prevent the inhalation of dust until lung-disease is firmly established. Minute particles of metal or stone being driven into the eye, cause pain, and, as they endanger sight, some of the men who are subject to such peril wear large spectacles lest blindness should come, and work have to be given up for a time, or altogether. But, as no immediate pain is felt when dust is breathed, means are seldom taken to protect the lungs.

MEASURES are about to be taken for the protection and preservation of the State forests of the colony of Victoria. A commission, appointed by the Government to inquire into the means to be adopted for this purpose, has recently made a report upon the subject. As illustrating the natural growth of timber in the more favourable districts, it is mentioned in the report that Mr. Percy Hodgkinson recently measured, near the source of the western branch of the Wori Yallock Creek, a tree (Eucalyptus amygdalina) that had been felled for splitting; its diameter, 1ft. above the ground, was 19ft., and at 70ft. from the butt-end 9ft.; its length in a straight line was 330ft. Many of the adjacent standing trees were, however, evidently of much greater height than this. A grove of the same kind of timber, at the head of the creek, contained on an acre of ground twenty large trees, of an apparent average height of about 350ft., and thirty-eight saplings of a height of 50ft., the whole being surrounded by a dense undergrowth of large fern-trees, musk, dogwood, &c.

A handsome testimonial, consisting of a service of plate, was presented on Saturday evening, by the workmen of the Millwall Iron Works, to their esteemed manager, Mr. John Hughes, and a gold watch to Mrs. Hughes. Mr. Hughes will be known to many of our readers as the inventor of the iron stringer backing for armour plates. Mr. J. L. O'Beirne, M.P., presided, in the large dining-hall attached to the works, and on the platform were Sir W. Wiseman, Bart., R.A., Captain Eardley Wilmot, R.N., Messrs. J. V. Gooch, C.E., J. Boyd, &c. The chairman observed that the works owed their creation to Mr. Hughes, and warmly testified to his personal worth. In himself he was a noble example of self-help, and had effected in one branch of industry the highest development of modern science and labour. Mr. Waring, in presenting the testimonial and address (which was tastefully illuminated) testified to Mr. Hughes' indefatigable energy and to his tact and kindly consideration, which had prevented his ever having had, in the long course of his management of this and other large works, a single strike amongst his workmen.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—2857, 2861, 2868, 2871, 2880, 2920, 2929
BUILDINGS AND BUILDING MATERIALS—2878, 2919
CHEMISTRY AND PHOTOGRAPHY—2852, 2874, 2893
CULTIVATION OF THE SOIL, including agricultural implements and machines—2905, 2916, 2930
ELECTRICAL APPARATUS—2879, 2909
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2885, 2914, 2926, 2928
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—None.
GENERAL MACHINERY—2854, 2855, 2856, 2862, 2863, 2867, 2872, 2877, 2881, 2883, 2887, 2890, 2891, 2895, 2899, 2901, 2903, 2906
LIGHTING, HEATING, AND VENTILATING—2853
METALS, including apparatus for their manufacture—2865, 2866
MISCELLANEOUS—2851, 2858, 2859, 2860, 2864, 2869, 2870, 2873, 2876, 2882, 2892, 2894, 2898, 2900, 2902, 2904, 2910, 2911, 2912, 2915, 2917, 2918, 2921, 2922, 2924, 2925, 2927
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2884, 2886, 2889, 2896, 2897, 2908
SHIPS AND BOATS, including their fittings—None.
STEAM ENGINES—2875, 2907, 2913
WARFARE—2888, 2923

2851 G. TWIGG. *Improvements in corkscrews.* Dated October 10, 1867.

This invention is not described apart from the drawings.—Patent completed.

2852 A. M. CLARK. *Improvements in the preparation or treatment of extracts of madder for dyeing and printing purposes, and in apparatus used in such treatment.* (A communication.) Dated October 11, 1867.

The details of this invention are too voluminous to be produced here at sufficient length for an intelligible abstract.—Patent completed.

2853 R. GEORGE. *Improvements in apparatus for warming and ventilating apartments or buildings.* Dated October 11, 1867.

This invention consists in forming a portable heating and ventilating apparatus with a chamber of thin sheet iron enclosing a grate or fireplace, the chamber being of such dimensions that the products of combustion will circulate within it for a sufficient time to part with a large proportion of their heat, and in arranging within such chamber a pipe or other contrivance of thin sheet iron through which a current of air passes from the exterior to the interior of the chamber or building to be warmed or ventilated, and, further, in so arranging the chamber or case and the pipe or contrivance through which the air is admitted that the burning fuel does not come in contact with them, but only the heated products of combustion arising from the combustion of such fuel, substantially as described.—Patent completed.

2854 J. WITHINSHAW and J. E. BAKER. *Improvements in steam pumps and blowing engines.* Dated October 11, 1867.

The patentees claim working or actuating the said slide valves by means of a lever worked from the piston rod of the pump or blowing engine, substantially as described and illustrated.—Patent completed.

2855 E. HAIGH. *Improved machinery or apparatus for planking the bodies of hats.* Dated October 11, 1867.

The patentee claims the production of the beating action upon the hat bodies from a number of beaters playing in pairs, such action being caused by the internal conical formation of the wheels, such formation causing the beaters gradually to approach nearer and nearer as the bodies become planked. He does not, however, confine himself to the precise details shown for effecting such beating action. Second, he claims the method of ejecting the bodies when planked; and, last, he claims the whole combined apparatus whereby hat bodies are planked by a beating action, and afterwards ejected from the machine, all substantially as described.—Patent completed.

2856 J. C. WILSON. *An improved rice unhusking mill.* Dated October 11, 1867.

This mill is constructed with two rollers, one of which is made of or covered with a hard substance, such as a metal, hard wood, stone, ebonite, &c., roughened on its periphery or external surface; the other is formed of (or with) a soft material, such as india-rubber, the periphery of the latter rubbing or squeezing, or both, the rice with the husk on it against the periphery of the former, whereby it is immediately unshelled.—Patent abandoned.

2857 J. C. WILSON. *Improvements in steam boilers.* Dated October 11, 1867.

This invention consists, first, in constructing the flues of steam boilers with a conical or bell-shaped mouth at one end, sufficiently large to permit of the withdrawal or insertion of the flues through that end of the boiler. Second, in the addition of small water tubes to boilers so as to increase their power, one end of the said tubes being open to the water space, and the other to the steam space of the boiler. This invention is not fully described apart from the drawings.—Patent completed.

2858 G. DAVIES. *Improvements in the manufacture of corsets, and in apparatus for taking measurements for the same.* (A communication.) Dated October 11, 1867.

This invention consists, first, of a very simple combination of "patternometer" for taking the measurements necessary for making a corset; and, second, of a new kind of corset made in two pieces united by one seam only; plaits or gathers, as well as the gussets for the skirt and top of the corset, are entirely dispensed with, which allows the corset to set well to the figure without distorting it in any way.—Patent abandoned.

2859 J. BRONNER. *An improvement in the construction of gas burners.* Dated October 11, 1867.

This invention relates to the construction of gas burners having any application by which the entrance of the gas into the burner is regulated. It has reference to a former patent, dated October 17, 1866 (No. 2679). The patentee gives to the lower hole-burner, instead of only two orifices as heretofore, a greater number of orifices—say, three, four, five, six, or more—which are distributed around the centre, whereby the gas is spread more completely than by two holes only, and it is forced to enter more equally and more regularly into the hollow body of the burner. This object is more perfectly attained by piercing the holes in an inclined direction, and by giving a concave convex form to the piece which is inserted in the burner and contains the holes. The larger the intended consumption of the burner the greater will be the number of orifices.—Patent completed.

2860 W. H. MAY and P. GRAHAM. *Improvements in stoppers for bottles and other vessels.* Dated October 11, 1867.

This invention is applicable to wooden stoppers, such as are described in the specification of a patent granted to M. Thompson, dated January 1, 1866 (No. 3). In order to make such stoppers more perfectly gas-tight, the patentees adapt short corks to them. They form an annular groove in the cork of a size to receive into it the hollow cylindrical end of the wooden stopper, also a coating or covering closing its exterior for some distance up, and a plug entering into the interior hollow. The central plug of cork may be also omitted, but this is not advantageous.—Patent completed.

2861 A. HELWIG. *An improved feed-water apparatus for maintaining a proper water level in steam boilers and other vessels.* Dated October 11, 1867.

This invention relates more especially to the means for supplying steam engine boilers and other similar vessels with water, and for preventing variations in the level of the water, and consequent injury to the boilers or other vessels. The apparatus is constructed with a chest or casing divided by a partition having two apertures somewhat similar to the ports of an ordinary steam engine. One of these apertures communicates with a cistern or other vessel containing water, and the other aperture communicates with the boiler, tank, or other vessel into which the water is to be forced. The partition of the chest or casing through which the two ports or apertures are formed is planed or otherwise made perfectly true on one side to form a face or bearing for a side valve, which is fitted to work thereon. The said valve is similar to the ordinary D-valve of a steam engine, and is provided with a rod or spindle which works through a packing box at one end of the chest or casing. The end of this rod or spindle may be connected with an eccentric, or other equivalent device, by means of which the required motion is communicated to the valve from a steam engine or other motive power. The D portion or cavity of the valve is made about the same width as the ports or apertures in the chest or casing, the valve being extended on one side of the chamber by a flange. This flange is of such a length that, when the cavity of the valve covers one of the ports, the other part or aperture is closed by the flange. The cistern or other reservoir from which the water is drawn must be placed at a higher level than the boiler or other vessel into which the water is to be forced. When, therefore, the valve lies with its cavity over the port or aperture communicating with the system, the water will fill the said cavity; the valve is then moved endwise till the cavity comes over the outlet port, when the water will pass therefrom through the said port into the boiler or other vessel being filled. When, therefore, the water in the boiler or other vessel has risen to the level of the top of the said casing, it will obviously not vary therefrom, so long as the working of the valve is continued. The cavity of the valve being brought alternately in communication with the inlet and outlet ports or apertures will keep up a continuous supply of water from the cistern to the boiler or other vessel being filled, and thus prevent the falling of the water therein below its proper level, while the arrangement of the valve to work inside the chest or casing prevents the rising of the water above the top thereof.—Patent completed.

2862 R. A. WRIGHT. *Improvements in the method of, and apparatus for, heating.* Dated October 11, 1867.

Here the inventor employs a solution of glycerine (which may be more or less concentrated), and which he uses in circulation pipes coiled where required. Also the heat may be applied to the solution of glycerine, or to other heating liquid, by means of friction, for the purpose of heating railway carriages.—Patent abandoned.

2863 E. LEITENBERGER. *Improvements in apparatus for separating soluble from insoluble matters, filtering the solutions, and, if wished, distilling these latter, or parts of them.* Dated October 11, 1867.

The apparatus for performing this invention cannot be described without reference to the drawings.—Patent abandoned.

2864 G. ANGELL. *Improvements in portable fountains.* Dated October 11, 1867.

This invention relates to improvements in portable fountains suitable for placing in rooms, conservatories, or in other positions, by means of which a continuous jet of water may be produced. The apparatus consists of a chamber of triangular or other form, on each face of which the inventor arranges a pump in such manner that, in all cases, one shall be forcing out water from the chamber while the others are taking in a supply, in order to produce a continuous jet of water. The chamber is divided into two compartments, the upper one of which communicates with the supply pipe and basin of the fountain, and the lower one with the fountain jet pipe. Each compartment also communicates with the several pumps by means of valves of india-rubber, or otherwise, arranged in such manner that the water passes continuously from the supply pipe and basin into the upper chamber, thence through the upper valves to the several pumps, upon the return strokes of which it is forced through the lower valves into the lower chamber, and up through the discharge pipe to form the jet, the water falling again into the basin to be again forced upwards, and so on.—Patent abandoned.

2865 W. E. NEWTON. *An improved mode of preparing iron for the manufacture of various articles where great strength and capability of resistance to tensile strain or torsion is required.* (A communication.) Dated October 11, 1867.

This invention relates to the manufacture of iron of great tenacity which will only break when subjected to very violent strain. This object is effected by the following means:—A number of iron rods, all of the same thickness (which must be in proportion to the size of the article to be manufactured) are to be worked cold, and then welded or brazed together to give the requisite size for the article required. All these rods should be straightened and united together with a faggot or pile, which is to be brought to a red heat until it has become sufficiently pliable to enable it to be twisted like a cord. Care should be taken at the same time to re-adjust such of the rods as had become displaced, and to preserve the regular form of the faggot or pile. When the faggot or pile has been twisted from one end to the other, it should be submitted to the ordinary welding and forging process until the rods (already firmly united by the twisting) form one compact and solid mass.—Patent completed.

2866 W. BUTLER. *An improvement in the rolling of hoop or strip iron for brewers' or other hoops.* Dated October 11, 1867.

It is a common defect in the use of ordinary iron barrel hoops that they have a tendency to slip, from the grip or bite being more in the middle than at the edges of the hoop. This defect the inventor obviates by rolling hoop or strip iron thinner in the middle, which may be done by a regular curve, or flattening the middle portion and raising the edges, so as to show a slight fillet or projection of the desired width on each side.—Patent abandoned.

2867 H. B. BARLOW. *Improvements in sewing machines.* (A communication.) Dated October 12, 1867.

This invention consists in certain improved parts and combinations of parts for producing an improved "whip stitch" or "point de feston," and they may be applied to all or most sewing machines in which shuttles are used. In this machine the needle is moved to and fro either horizontally or vertically, and the shuttle moves segmentally or horizontally. The principal novelty consists in the application of a swivel arm or bar, actuated by cam, tappet, or lever, and made with a spiral groove to unwind the thread off the shuttle, to hold it while the needle passes through the loop, and to tighten it again. Another part of this invention consists in giving the feed by means of a pair of spring nippers which vibrate on a fulcrum, and are opened and closed alternately by suitable levers and cams, or other equivalents, instead of giving the feed by the ordinary toothed feeder or propeller. The machinery above described is particularly adapted to sewing kid gloves, but it may be employed for sewing woven fabrics and other materials.—Patent completed.

2868 J. BUCKINGHAM and J. S. BLOCKEY. *Improvements in apparatus for regulating the feed of steam boilers.* Dated October 12, 1867.

This invention consists in the construction of an apparatus (substantially of the form described, and of the same principle) which shall, by the fall of the level of the water in the boiler, cause the pressure in the boiler to move a piston, which, connected with suitable mechanical contrivances, may be made to actuate the feed pump, or injector, or donkey engine.—Patent completed.

2869 C. H. COLLETTE. *Improvements in the construction of flights of stairs commonly called staircases.* (A communication.) Dated October 12, 1867.

This invention is carried out in the following manner:—The plan of a flight of stairs being given, the inventor takes a piece of sheet iron, or other metal of a sufficient thickness to resist the weight it may have to bear, and which serves for a string-board. He cuts in the iron plate the number of angles sufficient for the steps of the stairs, and, if of great height, as sheet iron is not made usually in great lengths, he adds to the length of the slips of sheet iron or iron plate other bands of iron plate, united end to end by joint plates screwed or riveted in the inside, sufficient for the height of the staircase. He then bends the plate according to the curves or squares necessary for the site or place of the flight of stairs. Each angle in the plate-iron string-board is cut rather deeper than would be necessary if in wood, to receive the back or heel of the tread, whether wood, iron, or stone. He cuts in each tread two longitudinal grooves, one at the heel of the tread above, and one in front of the tread below, into which the riser (which is of sheet iron, or other suitable metal, and which is of the same thickness as the string-board) can enter, and thus give greater rigidity. He makes use of the pieces of sheet iron cut out in forming the string-board, bending them into form of angle irons and supports, and the other pieces necessary for making the flight of stairs; thus no iron is wasted. These pieces serve in putting up the flight of stairs. The end of each riser he cuts at the end next the wall a little depth into the length of the riser, which is made rather longer than the width of the flight of stairs, and he bends one part forward and the other backward, so as to form a cramp or fastening in the wall, thus giving great solidity to each step, and, in case of fire, preventing the fall of the staircase. He fixes the balusters to the iron plate of the string-board instead of into the tread. To carry the plastering underneath the stairs he proceeds in the same manner as in other stairs, except that, instead of laths of wood, he fixes to the risers small pieces of iron cut from the string-board, which are riveted to and project below the tread, and carry strong iron wires longitudinally for the support of the plaster.—Patent abandoned.

2870 R. F. BARE and J. THOMSON. *Improvements in the conduction or transmission of fluids, and in the means, apparatus, or mechanism, employed therefor.* Dated October 12, 1867.

This invention is not described apart from the drawings. —Patent completed.

2871 J. B. P. A. THIERRY. *Improvements in smoke-consuming apparatus for steam boiler and other furnaces, and in machinery for manufacturing parts of the same.* Dated October 12, 1867.

This invention is not described apart from the drawings. —Patent completed.

2872 H. A. DUFRENE. *Improvements in apparatus for decorticating rice and other grain.* (A communication.) Dated October 12, 1867.

This invention relates to a former patent granted to the present patentee, dated June 11, 1866, and consists in forming the two friction surfaces of the decorticating apparatus, first, with vulcanized india-rubber and a hard rough biting body, such as emery, formed into an agglomerate, as described. Second, with vulcanized india-rubber and india-rubber covered with emery and vulcanized, or of two surfaces of the latter. Third, with india-rubber only.—Patent completed.

2873 R. CANHAM and J. THOMSON. *Improvements in stoves for consuming gas and other fuel, and in ovens to be used therewith.* Dated October 12, 1867.

This invention relates, first, to a novel combination and arrangement of parts of a stove for burning a mixture of gas and atmospheric air. For this purpose the patentees make the stove by preference of a cylindrical form. In the centre of the stove are fixed two cylinders concentric with each other, and having a small space left between them; these cylinders extend from the bottom to a short distance from the top of the stove, and are surmounted by a conical cover having a hole through it. The inner cylinder is closed at top and bottom by wire gauze, or perforated metal, and has a pipe therein through perforations in which the gas issues into such cylinder, and there mixes with atmospheric air, such mixture of air and gas being burnt on the top of the wire gauze, or perforated metal cover of the cylinder, the flame thereof being contracted by passing through the hole in the conical cover; atmospheric air is supplied to the flame by its passing up the space between the two inner cylinders, and is caused to impinge thereon by the conical cover. The products of combustion pass away by a pipe, one end of which is near the bottom of the stove, and open thereto, whilst the upper end passes out at or near the top of the stove.—Patent completed.

2874 E. LEITENBERGER. *Improvements in treating madder for the purpose of obtaining purpurine or alizarine from the same, and in apparatus to be made use of thereby.* Dated October 12, 1867.

This invention relates to new methods for obtaining the purpurine and the alizarine separately from madder, and consists, first, in certain new modes of preparing either madder, or what is called madder charcoal, viz., the results from the treatment of madder, by concentrated sulphuric acid, in such manner that, instead of containing both purpurine and alizarine, the same after the said preparation, contain only one of the said colouring principles. Second, in new modes of and apparatus for extracting from madder or from madder charcoal, prepared as above stated, the colouring principle left behind in the same, or existing in the wash waters.—Patent abandoned.

2875 H. FORMAN. *Improvements in the wheels of traction engines.* Dated October 12, 1867.

This invention consists in constructing the tyres or peripheries of the wheels of traction engines so as to cause them to grip or adhere to the ground. For this purpose the inventor makes on the tyres or peripheries of the said wheels a series of projecting bands or plates of iron or steel, the bands or plates being situated, by preference, equidistant from each other. The bands or plates pass in an inclined or oblique direction from side to side of the tyre or periphery, the bands or plates somewhat resembling in configuration, but broader than, the threads of a quick-threaded screw, or the threads of a worm wheel. The bands or plates on one wheel are disposed so as to run from right to left, and those on the opposite wheel to run from left to right. By these means the engine is made to travel in a straight line, the tendency of one wheel to move out of a straight line being neutralized by the other wheel.—Patent abandoned.

2876 J. DRABBLE. *Improvements in the mode of securing handles and scales to every description of cutlery.* Dated October 12, 1867.

Here, the handle is to be bored or pierced vertically to receive the tang, but the side and depth of the bore must be greater than the tang, and a hole must be pierced on the upper and lower surface of the handle (or on each side) communicating with the bore in which the tang is to be set; the handle is bevelled off, or cut out with a tool at that part where the bolster is to be formed, and the tang is perforated with one or more holes. The handle being fixed in a vertical position, the blade and tang are placed in position, and a mould is placed round the upper part of the handle, leaving spaces at the upper portion, where the handle is bevelled off or cut away. The openings at the side, or top and bottom, of the knife are then to be stopped by placing paper, or other porous substance, against them, which will yet permit of the escape of air. Then the soft metal is to be poured from a ladle down one side of the vertical hole in the handle; the metal will fall to the bottom, and eject the air from the cross holes, filling them up, and return afterwards, surrounding the tang, and filling the hole or holes therein, and, rising, fills up every cavity until it becomes flush with the upper line of bolster mould.—Patent abandoned.

2877 J. H. JOHNSON. *Improvements in knitting machines.* (A communication.) Dated October 12, 1867.

This invention is not described apart from the drawings. —Patent completed.

2878 B. NICOLL. *Improvements in the economical construction of buildings, also in rendering them more secure from fire and damp, and in preserving them from decay.* Dated October 12, 1867.

This invention is not described apart from the drawings. —Patent completed.

2879 W. R. LAKE. *Improvements in electric telegraph apparatus.* (A communication.) Dated October 12, 1867.

This invention is not described apart from the drawings. —Patent completed.

2880 J. C. PEARCE. *Improvements in furnaces and fire-grates.* Dated October 14, 1867.

Here the grate bars are connected together alternately, so as to form two or more lots, which, by way of distinction, are termed lifting bars and traversing bars; the former work up and down edgewise, and the latter backward and forward lengthwise. In a convenient situation, about the front of the furnace, is fixed a revolving shaft provided with cranks or eccentries, from which the required motions are communicated through suitable rods and levers to the grate bars. A hopper or other receptacle for the fuel is formed at the front of the grate, above the bars, and is fitted with an adjustable plate for regulating or stopping the supply of fuel to the furnace.—Patent abandoned.

2881 D. E. BLACKE. *Improvements in apparatus for spinning and twisting yarns.* Dated October 14, 1867.

This invention consists in the application of a friction plate or cone to the spool or bobbin in the process of spinning or twisting flax, tow, and other fibrous materials into yarn, the object being to drive the bobbin and contents by means of the above-mentioned plate or cone, and not solely by the yarn or thread, as is the case at present. This the inventor effects by causing the friction plate or cone which acts on the bobbin or spool to revolve with the spindle, the latter passing through the friction plate or cone, which has a feather, or other like contrivance, inside the hole, which feather fits into a corresponding slot in the spindle which is prepared to receive it. By this means the friction plate is carried round with the spindle at the same time that the bobbin works up and down in building.—Patent abandoned.

2882 E. WARD. *Improvements in hats and other similar coverings for the head.* Dated October 14, 1867.

This invention consists of a novel method of attaching the linings to the hat body, by means of which the hat more perfectly fits the head of the wearer, and at the same time the ventilation of the interior of the hat is promoted. In carrying the invention into effect the patentee makes the portion of the lining of the hat which comes into contact with the head, and which is usually made of leather, a suitable degree smaller in circumference than the inner circumference of the hat body to which it has to be attached, so that, when placed in its position, a space will be left between the lining and the said hat body. The connection between the said lining and the hat body is effected by attaching strips of leather, or other suitable material, to the lining and the hat body in such a manner as that one end of each strip shall be attached to the lining, and the other end to the hat body, it being preferred that a portion of the strips be reversed as regards the other portion, that is to say, that supposing the hat to be in a vertical position, as in wear, the lower ends of one portion of the strips which are now vertical will be attached to the lining, the corresponding ends of the other portion being attached to the hat body.—Patent completed.

2883 W. GADD and B. WALKER. *Improvements in means or apparatus for the manufacture of narrow fabrics.* Dated October 14, 1867.

This invention relates to means for producing upon the lace machine, or a modification thereof, narrow fabrics such as are usually produced in the loom, thereby obtaining much greater speed and an increased quantity of breadths at the same time. In carrying out the invention the warp of the fabric is supported in the lower part of the machine, but instead of all the threads being upon one beam, they are divided into sets, each set being wound upon a separate reel or spool. A number of these reels or spools are placed either in a continuous line upon a shaft running lengthways in the machine, or otherwise. Upon each spool or reel may be wound threads of warp sufficient for one breadth of fabric, which threads for each fabric are carried upwards through a sley in a line stretching from back to front of the machine, thence these threads pass through bars, which may be of the ordinary kind. If they are put in what are termed "top bars," such bars may be divided to their proper distances by means of points of the character of ordinary leads of points, or by sleys, or other suitable means. If bottom bars are used, the threads may be drawn through (in addition) a stationary reed, or a many-wired stump bar placed close underneath the carriage bottoms. By means of such bars a shed is opened in all the breadths through being actuated by jacquard, cam, or any suitable means for the passage of the bobbins and carriages which act as the shuttles, and thus form the fabrics with their edges towards the operator. The invention includes other features.—Patent completed.

2884 M. FITZPATRICK. *Improvements applicable to railway trains for the prevention of accidents arising from collisions or other casualties on railways.* Dated October 14, 1867.

This invention consists of an elastic cushion to be attached to the locomotive and carriages of a train in place of buffers. This elastic cushion will yield to any compulsory force, and deaden the effects of a collision. It is constructed exteriorly of leather, gutta-percha, or similar materials of the size, say, of 5ft. by 3ft., and 2½ft. in depth. Interiorly it is divided into three or more compartments, which are filled with blankets and wool, and is fitted with springs and with valves to admit of the entrance and exit of air. The invention further consists in retaining the break suspended when it is desired to reverse the engine, and this the inventor effects by means of a double-notched lever which grasps the cushion frame and raises the break legs from the rails.—Patent abandoned.

2885 W. REDGATE and T. MARRIOTT. *Improvements in the manufacture of lace in twist-lace machines.* Dated October 14, 1867.

Here the inventors obtain, on the edge of a band of lace, a purl like that of hand-made lace, or what is ordinarily called a twisted purl, in which the two sides of the purl loop across each other by the following means:—The purl loop is formed from a warp thread (or it may be from two warp threads for the time working together as one), and in the edge of the lace on which the purl is to be made they provide, to aid in producing the purl, two warp threads which they call closing threads, and two bobbin threads which they call edge bobbins. Immediately before commencing to produce the purl, one of the closing warp threads comes from a distance sideways and crosses one of the edge bobbin threads, then the purl warp, in going to make the purl, passes the same edge bobbin on the other side, and the purl warp and closing warp threads are then snared together by the edge bobbin thread. The closing warp then remains for a time without twisting, so that, as the work rises above the points, it becomes gradually drawn down or tightened, and it brings with it the root of the purl, sliding it down the edge bobbin; the bottom of the purl top is raised in a similar manner to that in which the top is depressed by means of the other edge bobbin; the purl warp thread is snared with the other closing warp thread, which previously had been standing for some time, and which immediately after is thrown a distance sideways; then, as the work rises above the points, the tension on this closing warp thread tends to raise the root of the purl, sliding it up its edge bobbin. As the top and the bottom roots of the purl are caught by separate closing warp threads, and separate edge bobbins, they are free to slide past each other on their edge bobbins, and so the purl loop is brought to the form desired.—Patent abandoned.

2886 H. N. MAYNARD. *Improvements in bridges, piers, and landing stages.* Dated October 14, 1867.

This invention consists in so connecting the pieces or

Digitized by Google

supports to hydraulic rams fixed in the bed of the river that, on working these by means of pipes from the shore, the piers or supports are either raised to the requisite height for supporting the roadway of the bridge or other structure, or they are lowered down level, or nearly so, with the bed of the river, when it is desired to make a free roadway for the navigation. When the pier or support has been raised to its full height, it is supported either by suitable locking bolts made to project therefrom into recesses in the foundation, or it may be supported in any other suitable manner.—Patent abandoned.

2887 W. R. LAKE. *Improvements in apparatus or machinery for loading heavy ordnance with balls, shells, or other projectiles.* (A communication.) Dated October 14, 1867.

The object here is to raise and place in the bore of the gun heavy shot, shell, or other projectiles by mechanical means, with the assistance of very little manual labour. The invention relates to the employment of a platform on which a bed is fitted to receive the shot, the platform being so arranged and combined with a steam cylinder or cylinders, or with other machinery operated either by steam or by hand, or by any other power that may be made applicable to the purpose, that the said platform may be raised or lowered to lift the projectile to the muzzle of the piece when the projectile is placed on the platform, and then introduce the said projectile into the bore. Two cylinders may be used, one being placed on either side of the carriage, and directly below the trunnions, with the piston rods extending forward in a horizontal plane, and attached to the lower ends of the vertical arms of two bent levers. One of these levers is placed on either side of the piece with its fulcrum located in about the same horizontal plane as the trunnions, and its horizontal arms extending as far forward as the muzzle, where it is attached to the aforesaid shot platform. As the said vertical arms are moved forward or backward by means of the steam applied to pistons within the cylinders, it follows that the forward ends of the horizontal arms of the said levers, and with them the shot platform and the shot itself, will be with ease elevated to such a plane that it may readily be rolled, if round, or caused to slide if elongated, into the muzzle of the piece. One cylinder might be placed beneath the piece, and made to serve the purpose of two by coupling its piston rod with both levers. Another device consists of a series of telescopic cylinders with their axes in a vertical or nearly vertical plane, and placed directly beneath the shot platform. As steam is introduced into these cylinders, they are raised up one out of another until the shot platform is of the proper height to introduce the ball into the piece. By having the shot platform hinged at its back end or side to the top of the upper cylinder of the series, and a guard connected therewith so as to extend under the gun, when the platform shall have been raised so as to cause the said guard to come in contact with the gun, and a little more steam is applied, the front end of the platform will be raised up while the said guard and hinge holds the back end of it down on a level with the bore of the gun, thus tipping the platform so as to allow the shot to roll off into the piece (if it is a round shot, or be pushed off if it is an elongated one) as soon as a spring catch which has hitherto retained it on the platform shall have been released.—Patent completed.

2888 W. R. LAKE. *Improvements in revolving batteries, and in the means for working the same.* (A communication.) Dated October 14, 1867.

Here, instead of surrounding the guns with armour which revolves with the battery, the inventor arranges the armour as fixed or stationary, or secured to the vessel bearing the same, and only movable therewith; and he arranges the battery within the said fixed armour movable in such wise that the battery may command all points of horizontal and vertical range which it may be necessary or useful to command. This he accomplishes by piercing the casemate or armour with the necessary number of embrasures or port holes, each being of such form as to permit the horizontal and vertical ranges aforesaid, and by arranging the battery on a platform which may, by proper mechanism, be rotated, thus rotating the battery thereon, and by arranging the guns or other weapons forming the said battery to move, with the carriages whereon they are placed, on proper slides, thereby admitting a motion of the said guns and their slides independently of the platform; and, last, by arranging to manœuvre the said guns or weapons on the said slides to run the same by means of proper mechanism into the positions for firing or loading. All the operations of manœuvring the battery may be effected either solely by the power of the operator's acting upon proper mechanical devices, or by the aid of steam, or similar power, controlled by operators. This invention is not fully described apart from the drawings.—Patent completed.

2889 M. A. F. MENNONS. *Improvements in apparatus for transmitting alarm signals and applying brake power in railway trains.* (A communication.) Dated October 14, 1867.

This invention consists in the application of the vacuum to railway alarm and brake working apparatus as a means of actuating a bell or other signal, or of transmitting motion to the brakes when required for the stoppage of the train.—Patent completed.

2890 H. A. BONNEVILLE. *Improvements in apparatus for superheating steam and other vapours.* (A communication.) Dated October 15, 1867.

This invention consists, first, in a novel construction and arrangement of pipes or tubes for the introduction and passage of steam or other vapours for the purpose of superheating the same, the main principles of which construction consist, first, in providing barriers to the passage of the steam or other vapour, and in so running or locating the pipes or tubes that the steam or other vapour will be made at points of its passage through the tubes to strike against the sides or surfaces thereof, and thus have its particles, as it were, so broken or separated as the more fully and perfectly to be subjected to the action of the heated currents circulating about or around the tubes of the superheater either more or less as the case may be; and, second, in so constructing the pipes composing the superheater that at the points thereof where the steam or other vapour impinges or strikes against the sides of the pipes and becomes broken up into particles as above stated, such steam or other vapour will then be allowed to expand when being again contracted in its further passage onward, a new column of steam or other vapour, as it were, is formed and exposed to the action of the heated currents until it is again broken up as before when again expanding and becoming contracted it passes. Third, in so constructing the superheater for heating the steam or other vapour with the boiler or boilers from which such steam or other vapour is being and has been previously generated that the superheated steam or other vapour can be conducted back into the boiler and there made to act upon and diffuse itself entirely or thoroughly. —Patent abandoned.

2891 H. A. BONNEVILLE. *Improvements in apparatus for threading needles.* (A communication.) Dated October 15, 1867.

This apparatus is composed of two little plates of metal, or some such analagous hard material, one of which is rigid, and of a certain thickness, whilst the other is much thinner, of a smaller size, and possesses a certain amount of flexibility when it is connected at one of its extremities to the larger plate by means of a screw. A slot proportioned to the thickness of the needle or needles for which the apparatus is intended is made in the rigid plate, starting from its outer edge, and extending to a little hole running right through the said plate, which hole is proportioned to the dimensions of the eye of the needle, and corresponding with the extremity of a conical hole made in an appendix fixed on the adverse side of the rigid plate. In order to thread a needle it is run down the slot between the two metal plates until its eye comes in front of the hole in the rigid plate, then the thread—the end of which tapered off, as usual—is inserted into the conical hold of the appendix, which assists its entrance, traverses the hole existing in the rigid plate and the eye of the needle, which is then drawn from the slot, carrying away the thread with it.—Patent completed.

2892 M. VOGL and H. V. DYK. *Improvements in articles consisting of muffs combined with bags or similar receptacles, and in the frames of such receptacles.* Dated October 15, 1867.

The main object here is to combine a bag or other receptacle with a muff in such a manner that the muff shall be of the ordinary round shape. The improvements consist, first, in the construction and employment of a frame for the bag or other receptacle constructed as hereafter described; and, second, in providing an arrangement for opening the bag or other receptacle from the inside of the muff. The frame consists of an arrangement for opening the bag or other receptacle from the inside of the muff, and comprises an upper and under part. The ends of these parts are curved to correspond to the circular form of the muff, and the upper part, when the bag is closed, comes upon the lower part. The upper part is pivoted to the under at one side of the frame, while the other side is provided with a depending catch or lock which locks into a corresponding appliance on the under part. To release the catch or lock, the patentees carry down from its under side a rod or projection extending to the inside of the muff; by pushing or moving this rod or projection by the hand inside the muff the catch or lock is released, and springs fitted between the two parts of the frame then raise the upper part.—Patent completed.

2893 A. AITCHISON. *Improvements in the treatment of hydrocarbons for the production of gas sufficiently permanent to be stored for lighting and heating purposes, and especially in the treatment of the hydrocarbons obtained by distilling or carbonizing coal, wood, and other carbonaceous materials.* Dated October 15, 1867.

This invention consists in first heating the hydrocarbons and other products obtained from the distillation or carbonization of coal, wood, and other combustibles, as also other hydrocarbons, so as to convert the volatile constituents thereof into the form of vapour, and in then causing such vapours to pass in a more or less finely divided state against highly heated surfaces, whereby such vapours are converted into gases sufficiently permanent to be stored for lighting and heating purposes—Patent abandoned.

2894 T. H. BAKER and T. WOODROFFE. *Improvements in treating sewage so as to purify the more fluid portions thereof, and recover some of the contained matters for re-use in manufacturing processes.* Dated October 15, 1867.

Here the sewage (or other liquid matters from towns or other places, or from works where manufacturing or other processes are carried on with a tendency to render impure the sewage or other liquid matters passing therefrom) is allowed to flow into wells or receivers, of which there may be several, to be filled in succession, if desired, better to meet the requirements or occasions of violent storms, or to obtain greater purification, or for other purposes. The matters passing into each of these wells or receivers rises upwards through filtering materials supported in a frame at the upper part of each of such wells or receivers, by which the watery or more fluid portion is separated therefrom, and as it rises above the filtering matter such more fluid portion may flow away by suitable conduits to a river or other watercourse; or it may be collected, if desired, for irrigation or other purposes. The invention also includes other features.—Patent abandoned.

2895 M. SAMUELSON. *Improvements in sewing machines.* Dated October 15, 1867.

This invention relates to that class of sewing machines wherein a reciprocating shuttle is employed in conjunction with a vibrating eye-pointed needle for producing what is known as the lock-stitch. According to one mode of carrying out this invention, the patentee proposes to actuate the shuttle by means of a rotary crank-pin in a disc on the end of the main shaft of the machine; this pin works in a vertical differential slot in an upright lever constituting the shuttle carrier, which vibrates on a fixed centre at its lower end. In order to give a quick motion to the shuttle whilst passing the needle at a point where there is the least stress upon the crank-pin or lever, he curves the upper portion of the slot, and with a view to further facilitate the quick passage of the shuttle case or holder on the top of the lever at a slight angle. In the arrangements above described the shuttle will reciprocate in the arc of a circle, but if it be required that the shuttle should have a rectilinear reciprocating motion, then he substitutes the vibrating slotted lever above described for a plate sliding along two horizontal guide rods, such plate having a vertical differential or curved slot formed therein in which works the crank, and being further provided with a shuttle case or holder at the upper end thereof. On rotating the said crank a to-and-fro horizontal motion will be imparted to the plate or shuttle carrier and shuttle along the guide rods above referred to.—Patent completed.

2896 W. R. LAKE. *Improvements in the construction of railways and railway carriages, and in the means for propelling the said carriages.* (A communication.) Dated October 15, 1867.

This invention is not fully described apart from the drawings.—Patent completed.

2897 H. A. LEVESON. *Improvements in pack saddles.* Dated October 15, 1867.

The object here is to construct pack saddles in such manner that they may be readily accommodated to fit any sized animal—a mule, a bullock, or a camel. The inventor constructs the tree of the saddle of one or more (by preference, two) pairs of bars of iron, or other suitable material, the two bars of each pair being pivoted to each other in a similar manner to the two halves of a pair of scissors; they are kept open at an angle to suit the sized back to which the saddle is to be applied by a bar fitted to their upper part, and formed with holes, through one or other of which a bolt or pin is passed to hold the tree bars in place; or instead of this fixing bar any other convenient appliance may be applied to keep the tree bars apart. The lower ends of the tree bars carry the ordinary pads, while their upper ends vary in shape according to the description of load or baggage they are intended to carry; for supporting a cannon lengthwise the two of each pair should form a curve or hollow, thus ⌣. —Patent abandoned.

2898 B. LATHAM. *Improvements in the means and apparatus employed for distributing sewage over land.* Dated October 16, 1867.

The patentee claims, first, distributing sewage upon the surface of land by means of closed passages, pipes, or conduits, the upper parts of which are uncovered by the soil, and in which uncovered portions apertures are formed for the escape of the sewage on to the land, substantially as set forth. Second, constructing closed pipes or conduits for conveying sewage on to the surface of land, arranged and operating substantially as described.—Patent completed.

2899 A. M. CLARK. *Improvements in apparatus for producing motive power by means of compressed air, water, or other liquid.* (A communication.) Dated October 16, 1867.

The chief feature of this improved motor is that it is worked by compressed air acting on a piston in a cylinder, which, during its motion, at same time stores and compresses a fresh quantity of air in a reservoir for feeding the working cylinder and acting on the piston.—Patent abandoned.

2900 A. and A. C. M. PRINCE. *Improvements in telegraphic communication by pneumatic means.* Dated October 16, 1867.

The documents relating to this invention are with the law officers, "under objection," and cannot at present be seen.

2901 F. D. FROST. *Improvements in rollers used in frames for drawing and spinning fibrous materials.* Dated October 16, 1867.

This invention consists in forming the front rollers used in frames for drawing and spinning or preparing fibrous materials with a groove of ⌣ shape in its periphery, and in placing in the bottom of this groove leather or other suitable yielding material. The ordinary lower roller or boss works in the groove, and draws the fibrous material through.—Patent completed.

2902 C. TINET. *Improvements in the construction of chairs.* Dated October 16, 1867.

Into the back of the chair, and in a line with the back legs thereof, the inventor screws four rings in a horizontal position, two rings being at one side, and two at the other, the top rings being fixed near the top of the back, and the lower rings to the rail carrying the seat. The rings at one side are intended to receive and hold an umbrella, and the other rings a stick. Each pair of rings carries a horizontal cross bar or rail hinged and hooked thereto, one bar being behind the top rail of the back of the chair, and the other bar behind the rail of the seat, and the use of these rails is to receive a coat or other pliable article. The coat being first folded is laid over or across the top bar or rail which is unhooked to receive it, and the bottom bar holds the lowermost part, and by these means the coat is compactly held. He proposes to affix bars or rails between the legs of the chair at the sides and back thereof, and a shelf of cane or other open work a few inches from the bottom of the legs to receive a hat or other small article, the space between the front legs being left open for that purpose.—Patent abandoned.

2903 E. GESSNER. *Improvements in the construction of fulling stocks or fulling machines.* Dated October 16, 1867.

This invention consists, first, in the employment of a trough, the position of which is capable of being changed relatively to the beaters, in such a way that it may either be brought nearer to or removed further from them, according to the thickness of the stuff that is to be operated upon, and which would naturally vary considerably. Second, in the arrangement and disposition of this trough by means of springs or weights, so as to render it movable and make it act elastically against the beaters, that is to say, to make it give more or less, according to the quantity of stuff that is placed between the beaters and the trough, and which often varies unequally during the operation. By arranging the apparatus in this manner, this variation in the position of the trough will be neither prejudicial to the stuff nor to the trough. Third, in the trough in which several beaters work side by side, being of the same width as the cloth to be fulled, the latter may be fulled not only throughout its entire length, but also its entire width. The double advantage of this is that it entirely does away with the false longitudinal folds which are so very prejudicial to the stuff; this process also accelerates the operation of fulling. Fourth, this invention consists in using two beaters placed opposite one another, attached together and united by a single eccentric, and acting alternately and each in an opposite trough. This arrangement constitutes a double fulling action, which, besides the advantages offered by the single fulling stock, offers several others that are peculiar to it. Fifth, the cover of the trough can be either opened or shut, like a valve or trap. This cover or lid, when it is closed, tends to keep the material warm and to effect a more complete and uniform fulling, but when it is open it admits of the cloth being introduced in and withdrawn from the trough easily and regularly.—Patent completed.

2904 W. E. NEWTON. *An improvement in the preparation of wood for increasing the sonorous quality of a piano, or other musical instrument to which the wood is to be applied in its construction.* (A communication.) Dated October 16, 1867.

Here the sounding boards, or other parts of pianofortes and other musical instruments, after they have been

Digitized by Google

reduced nearly or quite to the required shape and thickness, are submerged in a tank of chamber lye or urine, in which they are allowed to remain undisturbed for a month or longer, until they are thoroughly soaked and impregnated with the salts in the urine, after which the boards are to be taken out, and slowly dried at a low temperature in a kiln or oven, until every particle of moisture is dispelled.—Patent completed.

2905 D. PIDGEON and W. MANWARING. *Improvements in reaping and mowing machines.* Dated October 17, 1867.

This invention relates to improvements in harvesting machines known as self-acting side delivery reapers fitted with one driving wheel, and in which the cut grain is discharged in sheaves clear of the track of the horses by means of a rotating rake or rakes, the object being to simplify the construction of such machines. To this end the whole of the gearing, both that which drives the cutting apparatus, and that which operates the rotating rake or rakes, is contained in two frames, the first, termed the draught frame, having fitted to it the main axle, and the first motion shaft and the second, termed the gear frame, carrying the crank shaft and the rotating rake or rakes, together with the cutter bar and grain platform. The gear frame is pivoted to the draught frame in such a manner that the first motion shaft forms the centre of motion on which the gear frame (together with the raking and cutting apparatus and the grain platform) is free to move for the purpose of adjustment with respect to the ground.—Patent completed.

2906 J. OXLEY and G. WILSON. *Improvements in machinery or apparatus for cleansing casks.* Dated October 17, 1867.

The patentees claim, first, the combination of parts consisting of revolving frames and driving gear adapted for turning them with cages or carriers for the several casks, and driving gear adapted for turning each cage or carrier with its cask on its own axis, as described. Second, the combination of supporting rollers and a brush roller working in a trough containing water, with gearing adapted to impart to the supporting rollers and the brush roller their relative directions of motion and speeds, in order to cleanse the outsides of casks, in the manner described.—Patent completed.

2907 W. B. ADAMS. *Improvements in locomotive engines and appliances for better and safer working on railways, tramways, and common roads, parts being applicable to like purposes.* Dated October 17, 1867.

This invention is not described apart from the drawings. —Patent completed.

2908 M. WILKIN and J. CLARK. *Improvements in the means or mode of signalling upon railways.* Dated October 17, 1867.

This invention comprises, first, certain apparatus for depositing on the rails fog or similar detonating signals from the last carriage or van of a train whilst the train is in motion. Second, the erecting and working of signal posts or indicators along the line, so that, when a train has passed the first signal post, the line will remain blocked till the train shall have arrived at the second signal post, when automatic apparatus shall clear the first section of line, and the second section be in turn blocked, and so on to the end of the journey. Third, means for effecting the same object as the preceding, but by an interval of time, instead of distance. Fourth, arrangements for depositing and removing fog or signal detonating signals at a certain distance from a station when the usual distance signal is temporarily obscured. The details are too voluminous to be quoted here.—Patent completed.

2909 W. R. LAKE. *Improvements in electric telegraph apparatus.* (A communication.) Dated October 17, 1867.

We cannot here give space to the details of this invention.—Patent abandoned.

2910 E. SHAW. *Certain improvements in hoods for perambulators and Bath chairs.* Dated October 17, 1867.

This invention consists in the application of rods secured to the front framework of the hood of perambulators that are caused to project a short length below the bottom of the hood on each side of the carriage; on this projecting rod a small pulley secured to a connecting link is allowed freely to act, the said link being attached by means of an india-rubber or other spring to a hook or catch placed and secured near the back of the carriage in the mean or central position corresponding with the length of the projecting rod upon which the connecting link slides. Thus, when the bowl of the link is at the bottom of the projecting rod, the spring will retain the hood in its highest or open condition, and when the hood is closed, the pulley and rod will have slipped to the top of such rod, which retains or keeps the hood in its closed condition; by this means the hood is retained in whatever position it is placed, whether open or closed.—Patent completed.

2911 R. C. ROSS. *Certain improvements in mechanism for cutting paper and similar substances.* Dated October 17, 1867.

This invention consists in mounting the circular disc knife in bearings that are arranged so as to allow such knife to revolve in a fixed position; or the said bearings are arranged so as to cause such circular knife to advance whilst revolving. The material to be cut is fixed by clamps or otherwise, so as to rise in a direct line against the cutting cage of the knife, having thereby their edges clearly severed or cut; or, in case the knife is movable, whilst revolving the goods are fixed whilst being cut. At the opposite end of the knife from its cutting cage a hone or sharpener is adjusted, so as to keep the knife, whilst cutting and revolving, in a sharp and keen condition.—Patent abandoned.

2912 J. RIVES. *Improvements in casting metals, glass and other materials, and in apparatus employed for this purpose.* Dated October 17, 1867.

This invention has for its object the applying pressure to castings of molten metal, glass, and other fluid substances whilst they are solidifying, in order to render them dense and homogeneous. For this purpose the patentee places the mould in which the casting is to be made in a strong vessel which can be closed air-tight, and after the molten metal, glass, or other substance of which the casting is to be formed has been poured into the mould, he closes up the vessel and forces into it compressed air, by which a very high degree of pressure may be placed upon the metal or other substance during the time it is solidifying.—Patent completed.

2914 L. HAMEL. *Improvements in machinery for clipping figured net and similar fabrics.* Dated October 17, 1867.

In order to clip off from a figured net or similar fabric the loops of the ornamenting thread which passes from figure to figure, the patentee distends the fabric, and over the face thereof he mounts a frame or bar to which a motion to and fro is given endwise as respects the frame or bar, and transverse to the length of the fabric. The frame or bar has a number of cutters upon it, and instruments which take up the loops of the ornamenting threads and present them to the cutters to be clipped. Any convenient number of cutters may be used, and the more numerous the cutters the shorter will be the to and fro movement of the frame or bar.—Patent completed.

2916 T. BELL and J. RICHARDSON. *Improvements in machinery for decorticating or hulling rice and other grain.* Dated October 17, 1867.

Here the patentees employ a drum or cylinder of metal or steel hung on a horizontal revolving shaft, and a stationary but adjustable concave, also of metal or steel. The periphery or face of the drum or cylinder, and also the face of the concave, are formed with small round buttons or knobs, cast with the surface, such buttons or knobs being placed in vertical and horizontal lines, and so disposed that, as the face of the drum or cylinder rotates towards or against the concave, each vertical row of buttons or knobs is carried between two similar rows on the face of the concave.—Patent completed.

2917 G. M. WELLS. *Improvements in apparatus to be employed in the manufacture of boots and shoes.* Dated October 17, 1867.

This invention relates to the sockets or holders for the standards or supports employed for holding the lasts during the process of making and finishing boots and shoes, and has for its object the affording facility for placing or adjusting the last in any convenient position required by the workman. It is proposed to mount the standard which carries the last in a revolving socket, whereby the last is free to be rotated horizontally or angularly, so as to bring any side in front of the workman. This revolving or rotating socket may be used either in conjunction with the ordinary standard, or with a standard cast in one piece with a portion of the last. The revolving or rotating socket may be made in various ways. According to one mode of construction the patentee casts the outer ring or surrounding metal forming the fixed part or holder of the socket round the revolving block containing the socket hole, such block being, by preference, of a slightly spherical shape, in order to increase its strength, and to keep it in its place in the outer ring. There are modifications given in the specification.—Patent completed.

2918 J. BANNEHR. *Improvements in apparatus for supplying deodorizing matter to dry or earth closets, and in processes of, and apparatus for, treating the liquid portion of human or animal excreta after removal from such closets.* Dated October 17, 1867.

This invention is not described apart from the drawings. —Patent completed.

2919 J. CUBITT. *The preservation from decay of stone, metal, and other substances, and for hardening or glazing their surfaces, so as to prevent smoke or dirt from adhering to them.* Dated October 17, 1867.

Here the inventor applies to the surface to be preserved or hardened a liquid composition which has the property of hardening on the application of heat, and he afterwards heats the surface so prepared by means of a blast or current of hot air, vapour, gas, or flame forcibly impelled against it, or by means of a jet of superheated steam. The ingredients of the liquid composition or glaze will vary according to the nature of the substance to which it is to be applied. A composition of two parts of alumina, two parts of hydrofluoric acid, and one of caustic potash, afterwards rubbed up with ten parts of saturated solution of silicate of soda or potash, forms a good glazing liquid for several kinds of stone and brick.—Patent abandoned.

2920 W. TREDGOLD and J. M'NEIL. *Improvements in steam boilers and furnaces.* Dated October 17, 1867.

This invention relates to improvements in the construction of steam boilers and furnaces with a view to obtain largely increased heating surface, economy in fuel, and an almost entire consumption of smoke. To effect this the patentees provide the furnace with hollow firebars which pass under and beyond the bridge, and are firmly fixed at their rear ends, where they communicate with the water space of the boiler; these firebars incline downwards towards the front, where they terminate in a hollow chamber resting simply against the sides of the furnace, and free to move sufficiently to allow for the expansion and contraction of the firebars. The water supplied to the boiler first passes into a water head situate within the smokebox, where it becomes heated preparatory to entering the boiler. The water passes from the water head through a suitable pipe into the chamber supporting the front ends of the hollow firebars before mentioned, through which latter it is forced in the form of jets by the pressure of the supply by means of nozzles placed in the end of each hollow firebar, the inclination of the firebars facilitating the passage of the water and steam contained therein into the boiler. Air is admitted to the fuel at the front of the furnace above the firebars, the ashpit being completely closed at all times except for the removal of cinders. By this arrangement, the products of combustion are first caused to pass down through the firebars, and then up again between them behind the bridge, returning through the smoke tubes of the boiler into the smokebox at the front of the same, in which is the water head for heating the water contained as above mentioned before it enters the boiler, thereby effecting a saving of fuel. The heat and flame passing twice through between the hollow firebars and through the smoke tubes of the boiler afford an increased heating surface, at the same time that the smoke is consumed by passing downwards through the incandescent part of the fire.—Patent completed.

2921 J. HALE. *An entwining pocket gaiter or spiral legging.* Dated October 18, 1867.

Here the garter or legging is cut out of nearly a straight material, varying in length and breadth according to the size of the person they fit; one end of the bottom part is placed near the instep; the remainder is passed round the heel and brought to the front, where it is secured to that end with a button or other fastening; the shape then swerves, so that in continuing the coil the body of the portion already fastened is only partially covered at the top, the remainder as it is entwined rises and covers the leg; each coil is secured with a button or other fastening to the one it covers. When off the leg, it can be made into a small parcel and conveniently carried in the pocket. —Patent abandoned.

2922 F. PRUDENCIO, F. COOPER, and J. F. COTTERELL. *Improvements in stoppers for bottles, which improvements are also applicable to cocks for casks.* Dated October 18, 1867.

This invention relates to that class of stoppers for bottles and other like receptacles which are self-closing, and in which the valve or stopper itself is contained inside the bottle or other receptacle. The same arrangement may be used as a self-acting cock for casks and similar vessels. According to this invention the patentees construct a self-closing stopper, which does not necessitate any special form of neck, but may be applied to other suitable material which is free to slide through a metal or other collar, which rests on the top of the neck of the bottle or end of the cock, an india-rubber or other packing ring serving to keep the tube in a central position as well as to prevent any breakage at that part. The inner end of this sliding tube carries a disc valve of india-rubber, or other suitable material, which closes against the inner shoulder of the neck of the bottle, or against the inside of the aperture in the case of a cock. A helical spring surrounding the outer portion of the tube, and confined between the collar and a cap or dome on the extreme outer end of the sliding tube, serve, in conjunction with the internal pressure, to keep the valve perfectly tight. When it is required to draw off the contents of the bottle or vessel, it is simply necessary to depress or force inwards the dome or cap, whereupon the valve is opened, and the liquid passes through the tube and is discharged at the outer end thereof.—Patent completed.

2923 H. W. GARRETT and G. HOLCROFT. *Improvements in firearms and ordnance, and in cartridges for the same.* Dated October 18, 1867.

This invention is applicable to breech-loading firearms and ordnance, and consists in connecting the barrel to the breech-piece by means of spiral projections on the one fitting into a spiral groove or grooves in the other, by which contrivance, when the barrel is drawn forward, or the breech-piece is pulled back, the chamber to admit the cartridge is opened, and when the barrel is pressed back, or the breech-piece is pushed forward, the firearm or piece of ordnance is ready to be discharged. The improvement in cartridges may be applied to cartridges for every description of firearms and ordnance, and it consists in introducing a small thread or portion of gun cotton or fulminate into or through the gunpowder of the cartridge for the purpose of producing instantaneous combustion thereof.—Patent completed.

2924 H. SHARP and F. W. WEBB. *Improvements in the manufacture of smiths' anvils.* Dated October 18, 1867.

Smiths' anvils now in use are generally forged of iron and faced with steel, the horn or horns being welded to the body of the anvil. Now this invention consists in casting anvils either wholly or partially of Bessemer or other cast steel.—Patent completed.

2925 E. CASPER. *An improved mode of, and means for, preventing the bursting of the tubes in steam and water pressure gauges, and other tubes or pipes, from the effects of cold.* (A communication.) Dated October 18, 1867.

The patentee claims preventing injury to the tubes of pressure gauges, and to other tubes and vessels when water freezes in the same, by placing within such tube or vessel an elastic or compressible body, substantially as set forth.—Patent completed.

2926 J. HILL and S. SHELLEY. *Improvements in the method of preparing weft that will enable the plain loom to weave checks or stripe goods.* Dated October 18, 1867.

The patentees claim, first, the method or process described of preparing weft whereby checks and striped fabrics can be woven in an ordinary single shuttle loom. Second, the machinery described, or any modification or arrangement of machinery, for winding or reeling yarn, and dividing each hank into two or more portions. Third, dyeing or printing the different portions of the hank so divided of different colours, or dyeing or printing one or more portions and leaving other portions without colour, so that the yarn is partly coloured in alternate lengths.—Patent completed.

2927 E. T. HUGHES. *Improvements in the manufacture of hats and bonnets, and in the apparatus employed therein.* (A communication.) Dated October 18, 1867.

This invention relates to hats and bonnets made of cloth, and consists in forming on the outside of the hat or bonnet a design or pattern similar to the plaits of the straw or grass hats and bonnets at present in use.—Patent completed.

2928 W. H. TASKER. *An improved shuttle eye.* Dated October 18, 1867.

This invention relates to shuttles employed in looms for weaving, and consists in the construction and application thereto of glass eyes instead of the pot or metallic eyes heretofore applied, which, by the constant friction or rubbing of the weft yarn in its passage therethrough, the said yarn is chafed and frequently broken thereby.—Patent abandoned.

2929 J. SEWARD and H. SMITH. *Improvements in steam boilers.* Dated October 18, 1867.

This invention has for its object the prevention of deposit in the flues of boilers of particles of incombustible matter. This the patentees effect by means of a series of plates fixed at intervals along the flues, the particles of incombustible matter being carried along the return flues and deposited in a pit prepared at the front of the boiler, or other convenient place, to receive the same.—Patent completed.

2930 T. KITCHEN. *Certain improvements to be applied to the grinding of wheat and other grain.* Dated October 18, 1867.

The object here is the carrying off and discharging the dust or particles of grain in suspension arising from wheat or other grain when undergoing the operation of grinding, without the aid of exhaust pumps, fans, or blasts, as heretofore employed, and the invention consists in the use of pipes, tubes, or trunks connected with an exhausting power to induce a current of air between the millstones, of sufficient power to carry off and discharge the dust or particles of grain in suspension.—Patent abandoned.

PROVISIONAL PROTECTIONS.

Dated February 15, 1868.

504 J. A. Hogg, Montague-street, Edinburgh. Improvements in the method of, and means for, increasing the combustion and illuminating power of gas.

Digitized by Google

Dated January 27, 1868.

656 R. A. Hope, Brelade House, St. Clement's, Island of Jersey. A machine for adding sweetening and other ingredients to aerated, mineral, and other beverages.

Dated March 17, 1868.

904 H. H. Hazard, New Cross-road, Deptford, Kent, engineer. Improvements in coiling or revolving shutters.

Dated March 24, 1868.

998 F. W. Crohn, Cullum-street, Fenchurch-street, City. Improvements in turbine apparatus for obtaining power from a fall of water.

Dated March 27, 1868.

1048 A. Scott, Blomfield-crescent, Paddington. The production of an alcoholic fermented dry sweet, or effervescent drink, of which tea or coffee or theine or caffeine is an essential ingredient.

1059 W. W. Hughes, Porchester-terrace, Middlesex. Improvements in apparatus for propelling and steering vessels, and in forcing water.

Dated April 2, 1868.

1112 J. Saxby, Kilburn, W., railway signal engineer. Improvements in apparatus for actuating, locking, and regulating railway switches, points, and signals.

1115 A. Jackson, braid manufacturer, and J. Hartley, foreman mechanic, Manchester. Improvements in braiding machines.

1117 J. G. Dale and E. Milner, Warrington, Lancashire. An improved method of producing white pigments from lead.

1119 J. Napier, Glasgow, engineer and shipbuilder. Improvements in apparatus for steering ships and vessels.

Dated April 3, 1868.

1121 J. and T. Walmsley, Little Harwood, Lancashire. Certain improvements in apparatus to be employed for warping and beaming yarns or threads.

1123 J. S. Crosland, Manchester, engineer. Improvements in, or applicable to, steam engines.

1125 J. Wallace, Glasgow, agricultural implement maker. Improvements in apparatus for digging potatoes.

1127 J. Harwood, Blackburn, Lancashire, sewing machine maker. Improvements in sewing machines.

1129 A. Martin, Middle-street, Clothfair, Middlesex, bonnet shape manufacturer. Improvements in bonnet shapes.

1131 J. V. Jones and G. J. Williams, Birmingham, manufacturers. Improvements in the manufacture of ornamental metallic tubes.

1133 W. Williams, Tividale, Staffordshire, tin plate manufacturer. Improvements in the manufacture of tin and terne plates.

1135 T. Row, Old Ford, Bow, Middlesex, and S. Scott, paper stainer, Chelsea, Middlesex. Improvements in the manufacture of paper hangings.

Dated April 4, 1868.

1137 H. Cochrane, Middlesborough-on-Tees, Yorkshire. Improvements in blast furnaces.

1141 A. and H. Illingworth, Bradford, Yorkshire, worsted spinners. Improvements in means or apparatus employed in folding worsted or other yarns.

1143 F. H. Greenstreet, Pattingham, near Wolverhampton. Improvements in targets, arrows, darts, and other projectiles more especially adapted for indoor use and amusement.

1147 D. C. M'Ivor, Asknish, Loch Gair House, Argyll. Improvements in propelling ships, and in the means or apparatus employed therefor.

Dated April 6, 1868.

1149 H. and J. Bryceson and T. H. Morten, Stanhope-street, Euston-road, Middlesex. Improvements in the construction of organs, and in the application of electricity thereto.

1150 D. Crichton, machinist, W. Donbavand, scale beam and weighing machine manufacturer, and D. Crichton, engineer, Manchester. Improvements in looms for weaving.

1151 E. Hay, Lombard-street, City. Improvements in means or apparatus for measuring and indicating the passage or flow of liquids. (A communication.)

1153 R. Morcland, jun., and D. Thomson, Old-street, St. Luke's, Middlesex. Improvements in pumping engines and steam boilers therefor, which steam boilers are also applicable to other purposes.

1154 C. H. Gardner, West Harding-street, City, printing machine manufacturer, and J. Bickerton, Oldham, Lancashire, engineer. Improvements in lithographic, zincographic, and typographic printing machines.

1156 J. M. Plessner, Rue de la Chausee d'Antin, Paris. Improvements in the mode of, and apparatus for, obtaining motive power.

1157 J. Radcliffe, Consett Iron Works, Durham. Improvements in processes and means employed in the manufacture of iron and steel.

1160 T. Holt and H. Spencer, Rochdale, Lancashire, agents. Improvements in machinery for spinning and doubling cotton and other fibrous substances.

1161 A. V. Newton, Chancery-lane. Improvements in bathing shoes. (A communication.)

1162 A. V. Newton, Chancery-lane. Improvements in anchors. (A communication.)

1163 J. Casson, St. James's-street, Sheffield, Yorkshire. Improvements in machinery for planing wood.

Dated April 7, 1868.

1164 E. Watteau, Vulcan Works, Middlesborough-on-Tees, Yorkshire. Improvements in screw taps, and in the mode of fixing the same.

1165 R. Holiday, High-street, Poplar, Middlesex. Improved means or apparatus for the prevention of accidents at facing points on railways.

1166 H. J. Ditmars, Pancras-lane, City. Improvements in apparatus for the consumption of smoke. (A communication.)

1168 W. Nall, Leicestershire. An improved apparatus for holding and igniting matches.

1169 E. H. Newby, King William-street, City. An improved boat-detaching apparatus. (A communication.)

1170 H. Fisher, Sheffield, Yorkshire, manufacturer. Improvements in constructing the handles of tea-pots, coffee-pots, or other vessels intended to contain heated liquids.

1171 F. Simpson, machine fitter, and S. Hardwick, metal roller, Handsworth, Staffordshire. Improvements in machinery for rolling sheets or plates of iron for the manufacture of tin and terne plates, which improvements may also be used for rolling sheets of iron for other purposes.

1172 C. W. Siemens, Great George-street, Westminster. Improvements in the application of gas furnaces to evaporating, smelting, puddling, and other manufacturing purposes.

1173 I. Sherwood, Birmingham, lamp manufacturer. Improvements in lamps for burning hydrocarbon oils and spirits.

1174 R. G. Lowndes, bleacher and finisher, Auldhousefield, Renfrewshire. Improvements in finishing textile and other fabrics, and in the machinery or apparatus employed therefor.

1175 J. Armstrong, Clifton, Westmoreland, agricultural implement maker. Improvements in harrows.

1177 D. Lane, Cork, Ireland, secretary to the Cork Gas Consumers' Company, Limited. Improvements in the manufacture of floor and other cloth or coverings for floors, and in covering floors.

Dated April 8, 1868.

1179 J. Bedford, Leeds, engineer. Improved means and apparatus for washing and drying grain.

1180 J. J. Chaudun and J. J. Dexant, Rueil Village, near Paris, manufacturers. Improvements in cartridges for breech-loading firearms.

1181 J. James, Ebbw Vale, manager, and T. Jones, Govilon, forge and mill manager, Monmouthshire. Improvements in the manufacture of iron into semi-steel or steel.

1183 W. R. Lake, Southampton-buildings, Chancery-lane, Middlesex. Improvements in machinery for cutting and working rocks. (A communication.)

1184 W. E. Newton, Chancery-lane. Improvements in the manufacture of salts of soda. (A communication.)

1186 C. G. Hill, Alfred-street, Nottingham. Improvements in the manufacture of fringes and purl.

1187 V. Gallet, Lavausseau de Berassais, department of the Vienne, France. Improvements in the manufacture of steel.

1188 E. Brasier, New Cross, Surrey, and J. E. Hodgkin, Liverpool. Improvements in machinery and processes for scutching, dressing, cleaning, treating, and preparing flax and hemp.

1189 T. Hunt, Godolphin-road, New-road, Hammersmith. Improvements in ordnance, and in the mode of working the same.

1190 C. Douglas, Edinburgh. Improvements in cutting the teeth of wheels, and in apparatus employed therein.

Dated April 9, 1868.

1191 W. Chapman, Kennington Park-road, Surrey, leather seller. Improved machinery or apparatus for skiving or chamfering leather and other materials.

1194 J. Rae, Sydenham, Kent, engineer, and G. Miller, Glasgow, rivet manufacturer. Improvements in the construction of railway wheels, and in the axles and bearings for the same.

1195 A. H. Still, Rockboro' House, and D. Lane, South Mall, Cork. Improvements in the manufacture of gas.

1196 W. B. Robins, South Moulton-street, Oxford-street. Improvements in garden engines and other similar hand pumps for throwing jets of water.

1198 G. T. Bousfield, Loughborough Park, Brixton, Surrey. Improvements in dies and in machinery for cutting dies and taps. (A communication.)

1200 W. E. Newton, Chancery-lane. Improvements in firearms and in cartridges for the same. (A communication.)

Dated April 11, 1868.

1204 J. Marsden, Bolton, Lancashire, builder. Improvements in the construction of beams or girders, floors, and roofs for fireproof buildings.

1206 C. E. Brooman, Fleet-street, City, patent agent. Improvements in photography. (A communication.)

1214 M. A. F. Mennons, Rue de la Chaussee d'Antin, Paris. Improvements in apparatus for the preparation of carbonated or effervescent beverages. (A communication.)

Dated April 13, 1868.

1218 B. J. B. Mills, Southampton-buildings. Improvements in bleaching, reviving, and tinting white and coloured feathers and silk fabrics and goods. (A communication.)

1222 T. Forster, Streatham, Surrey. Improvements in the manufacture of compounds of india-rubber, gutta-percha, balata, parkesine, solid paraffin or vegetable oils, and vegetable fibre.

1224 E. Richardson, Castle-street, Falcon-square. Improvements in stays or corsets.

Dated April 14, 1868.

1228 E. Foden, Sandbach, Chester. Certain improvements in apparatus to be employed for mowing and reaping.

1230 E. P. H. Vaughan, Chancery-lane. Improvements in the manufacture of ceramic tesserae and in the employment thereof for mural and other decorative purposes. (A communication.)

1232 H. Hughes, Homerton, engineer. Improvements in the manufacture of pipings and folds or plis of satin or other material.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," April 28, 1868.

3548 L. A. Damm. Means for conveying salt water fish through fresh water, and overland, and on land. (A communication.)
3560 R. Tinkler. Churns.

3635 C. G. Wilson. Machinery for pressing cotton.
3640 J. Rowe. Miners' safety lamps.
3641 W. Dixon and W. Brown. Elastic coupling for the prevention of sudden strains upon ropes.
3642 C. W. Lancaster. Construction of cannons.
3643 W. W. Urquhart and J. Lindsay. Machinery for softening jute.
3652 F. A. Abel. Production of explosive compounds.
3663 J. Addie and F. Kohn. Blast furnaces.
3666 W. Hewitt. Holders for holding reins.
3708 M. A. F. Mennons. Accelerating the induration of certain descriptions of concrete. (A communication.)
3716 W. Wilson. Hats. (Partly a communication.)
2 W. R. Lake. Fireproof safes. (A communication.)
7 A. M. Clark. Breech-loading ordnance. (A communication.)
8 H. Milward. Needle-cases. (A communication.)
14 T. B. Daft. Construction of iron ships.
17 D. Foster. Anvils for smiths.
44 F. Chamberlain. Steam boiler furnaces.
89 R. Winder. Folding machine for folding sheep.
112 T. Whitwell. Furnaces.
158 R. Heathfield. Machinery for the manufacture of nails. (A communication.)
320 B. Dobson, W. Slater, and R. Halliwell. Machines for spinning and doubling.
634 G. T. Bousfield. Apparatus for raising and forcing water. (A communication.)
684 T. Trotman. Doubling-up or folding carriages.
887 H. A. Bonneville. Permanent way of railroads. (A communication.)
970 V. A. Deaubeuf. Machinery for the manufacture of compressed fuel.
1028 J. T. King. Apparatus for dressing millstones.
1065 J. Macintosh and W. Boggett. Boots and shoes.
1121 J. and T. Walmsley. Apparatus for warping yarns.
1137 H. Cochrane. Blast furnaces.
1186 C. G. Hill. Manufacture of fringes.
1222 T. Forster. Manufacture of compounds of india-rubber, &c.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed April 24, 1868.

3000 W. and D. Fisken	3034 A. J., W. B., and S. H. Waterlow
3010 P. Love	3030 H. A. Bonneville

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, MAY 8, 1868.

THE GOVERNMENT AND THE TELEGRAPH COMPANIES.

IT would have been matter of great surprise if the Government bill for obtaining the electric telegraphs had not met with opposition from the various telegraph companies. The bill, as it stood, was capable of great improvement, and opposition usually has the salutary effect of detecting the weak points, and consequently necessitating certain amendments. On this account we are glad to see the pamphlet lately published as a "Statement of the Case of the Electric and International Telegraph Company against the Government Bill." This is generally credited as the work of their chairman, Mr. Grimston; and as we have seen similar matter in a more condensed form under his signature, we may be fairly permitted to accord to him the credit of the work. We cannot enter into its consideration without expressing our admiration of the bold and plucky way the attack is made. No opposition has appeared from any of the other telegraph companies—unless we can call the petitions presented to Parliament against the bill by individual shareholders, by that name—so we may take the pamphlet as expressing the views of all, especially when we find it remarked that they "for their own part, as well as for that of the other companies, deny, &c." Almost simultaneously with the above, was published by the House of Commons, a "Return relating to Electric Telegraphs," giving the various reports made to the Postmaster-General, and which we must take as the foundation of the bill itself. It is somewhat unfortunate that the return did not make its appearance earlier, for it would then have saved the company from several inaccuracies and mis-statements. The return contains the original and exhaustive report of Mr. Frank Ives Scudamore, and his second report, the latter giving answers to many points brought before us in Mr. Grimston's pamphlet. We may mention, before proceeding further, that the pamphlet attributes the origin of this scheme jointly to Mr. Scudamore and Mr. Chadwick, the latter of whom read an independent paper on the subject at the Society of Arts, in the discussion of which Mr. Scudamore joined. The scheme was really exciting the attention of the Government prior to that event, and we think we are correct in stating that their attention was originally drawn to it, strange to say, by a letter from the late Mr. Ricardo, who was one of the promoters of the Electric Telegraph Company, and was for many years their chairman. The letter being written after his official connection with the company had ceased, may account somewhat for their ignorance of it; but the many proposals on the subject by Mr. Thomas Allan, the well-known telegraph engineer, remarked so freely on in the press at the time of their appearance, ought to have been known to them.

The pamphlet reviews the Government bill, what it proposes, what the Electric and International Telegraph Company has effected, the great question of the Belgian and Swiss telegraphs, the plans of the Post-Office, and, finally, the Government control, showing its disastrous effects. It would have been far better if the latter section had been left out, for its want of taste mars the effect of the arguments entirely. In discussing the bill they dispute "the truth of the preamble, and take issue on it boldly, that the means of communication by electric telegraph are insufficient." In spite of the boldness of their statement, we certainly do not think they have satisfactorily contradicted it, neither have they made any attempt to refute the petition presented to the House of Commons by the Association of the Chamber of Commerce of the United Kingdom, complaining not only of the high rates, but of frequent and vexatious delays, and of inaccuracy, &c.; and also a special report of the Edinburgh Chamber of Commerce with similar complaints. It is not so much on their own account that the Government have worded their preamble in such a manner, but almost entirely upon the representations made to them. We do not expect for a moment that the Telegraph Company would admit any of these allegations, just as we should not imagine that a tradesman would run down the wares he was about to offer for your purchase.

The reports upon which the Government drew up their bill not having been before the Company until after their pamphlet had appeared, this part of their statement is not so complete as it otherwise would be, but the statistics of the Swiss and Belgian telegraph systems are fairly used by them, and they make a strong case, by taking these statistics, that our system is not inferior to theirs. Certain statistics brought forward by them show this result, whilst others brought forward by Mr. Scudamore show a different result, proving how statistics may be taken for or against. One point the company bring against the Belgian Government is, that "no matter how long a message has taken in delivery, or whatever may be the errors in it, they will make no compensation to the sender or receiver, except under very exceptional circumstances." Of the value of this argument in favour of the Company, we make the following extract from the Electric and International Telegraph Company's forwarding form. "The Company will not be responsible for *inaccuracy* in the transmission of any message along the Company's lines, unless the message be an insured message. The Company will not be responsible to any extent whatsoever for any delay in the transmission or delivery of *any message, whether the message be insured or not.*" The italics are not our own.

The Company make out a very good case of what they have effected. Too much praise cannot be awarded them for what they have done towards improving telegraphy in the United Kingdom. Personally, we do not consider our system inferior to that of other countries, and we do not question, neither to our knowledge has it ever been questioned, but that we owe much to the various telegraph companies, and principally to the Electric and International Telegraph Company, for what they have done; but it must be acknowledged that, being compelled to look after the profits of the concern, so as to return a good dividend to their shareholders, prevents them from giving the public more extended and cheaper communication. It is a great commercial undertaking with them, necessitating a good return for the capital expended; the dividends the shareholders annually receive proves that the directors have not been unmindful of their trust. The Company have done what they can, but we contend that an amalgamation of the various systems under the Government would infallibly bring about the result of a cheaper system of telegraphy, which could only be effected by the companies at the cost of dividends. We have already expressed our opinions on the subject, with which our readers are doubtless familiar. We will only state here our conviction that the Government would be able, under a general and a more economic system, to work the telegraph at greatly reduced rates, and still with a profit.

An argument was made use of by Mr. Grimston, in his former pamphlet, which we see repeated in the one before us, relative to the value of telegraph stations in a pecuniary sense. "The following simple statement will suffice to dispel the illusion" that "a cheap system of working the telegraph in connection with the Post-Office would enable them to reduce the rates in the general system." "The great bulk of the stations of the Electric and International Telegraph Company only collect 9 per cent. of its gross receipts. In 1867, of the gross receipts of the Company, 76 per cent. was received at eighteen stations, 15 per cent. at eighty-one stations, and only 9 per cent. at the remaining stations." "It is obvious, therefore, that it is not the small stations that pay." It is sufficiently obvious to us (a point also Mr. Scudamore has not been slow to make use of) that the Company places a value purely one-sided on their traffic. It simply amounts to this, that the value of a station does not depend at all upon its received messages. In fact, that it only exists for forwarded messages. If these small stations, therefore, had no existence, would the larger stations send those messages? The argument is certainly a weak one, and damages the case of the Company. The value of any station—telegraphic, railway, or postal—can only be fairly estimated by taking into consideration the traffic received at it as well as that forwarded from it.

The Company enter largely into the confusion that would arise relative to the contracts they have in hand, agreements between them and the various railway companies, and want to know what the Government intend doing as regards them. One clause in the bill specially provides for this point—that all matters undertaken by the Company will be carried on by them, "as if the Postmaster-General had been named" "instead of the Company." As regards press messages and other extraordinary traffic, we cannot think so badly of the Government as to imagine they would exercise *espionage* or any undue influence politically with regard to such telegrams. We should have been ashamed to bring forward such a suspicion. What would be the opinion of the directors were we to hint such a thing against them? The chapter on Government control is one we are sorry to see in the pamphlet, and one which must leave an unfavourable impression against the authors of the pamphlet in the minds of those who read it.

There are many points in the pamphlets which call for attention, but our space will not allow us to discuss it more. The opposition that the Company has brought to bear will, no doubt, be beneficial; but for all the arguments they have brought forward, we cannot agree with them that "it is undesirable that the telegraphic system of the country should be placed in any way under Government control;" and, on the contrary, we are still firmly of opinion that under the change we should have an equally, if not more, expeditious, and decidedly a cheaper system of electric communication.

IMPROVEMENTS IN OUR PUBLIC CONVEYANCES.

THE question of the improvement of our public conveyances is one which has been much discussed of late. That there is room for improvement no one will deny who is acquainted with the tightly-packed, unwholesome-aired, noisy, jolting omnibus of the present day. In his tramway system Mr. Train set us an example of what might be done towards enabling the public to travel in comfort. But he used a rail which interfered with the general traffic, and so the system fell into disrepute. More recently we have had Messrs. Noble and Co. endeavouring to revive the tramway system, under Parliamentary sanction. Vested interests, how-

Digitized by Google

ever, and a powerful carrying company, have, we regret to say, been the cause of the bill being thrown out. So for a time, at least, we must rest contented with our present miserable system. We hope, however, that next year Messrs. Noble will be more successful with their bill, and that, with certain necessary exceptions, we shall see our thoroughfares laid with a judicious system of street tramway. The mechanical arrangements proposed by Messrs. Noble are simply unobjectionable, and cannot in any way interfere with existing traffic. In the meantime, however, and pending better things, it should be the duty of Government to insist upon the public being provided with a decent class of conveyance, which, we are sorry to say, the present ordinary omnibus is not. Several improvements have been made from time to time, and most of our great exhibitions have included examples of convenient and comfortable omnibuses. But improvement has rarely gone beyond that, and the designers and builders of these vehicles have, for the most part, had their trouble for their pains. We have now another enterprising gentleman who has worked out with great care, and at considerable cost, a novel system of omnibus, which promises well for the public convenience and comfort, if only the powers that be will back the inventor's exertions to obtain its general adoption. This gentleman is Mr. William Harvey, who is well known to our readers by his recent letters upon the quadrature of the circle, and other mathematical subjects.

We last week briefly announced that a trial trip was to be made with Mr. Harvey's omnibus. Pursuant to notice, and punctual to time, on Friday last, at 3 p.m., it left Charing-cross for a run to the Bank and back. This trial was made by direction of the Home Secretary, who specially appointed Mr. George Lane Fox to superintend it. A number of scientific gentlemen and others interested in the question of improving our public vehicles were among the passengers, Sir Richard Mayne directing the operations from the roof. The chief peculiarity of this omnibus consists in its having only two wheels, and being drawn by three horses. The horses are attached to the vehicle by means of four shafts, so that, as the back and belly bands of the horses traverse freely from the near side of the near horse to the off side of the off horse through swivel holes in the centre shafts, and as there are only two wheels to the omnibus, the three horses act together as one horse in a gig or Hansom cab. For the purpose of preventing noise, the shafting and framework of the running frame are put together as one piece, and are composed entirely of angle and bar iron. This framework rests by strong and long grasshopper steel springs on the single cranked axle, the arms of which are 3¼in. in diameter, and the wheels have a run of nearly 8ft. The carriage body rests on the top of the iron frame on four india-rubber cylindrical buffer springs, and swings entirely free of the axle. This completely prevents the ordinary sharp rattle experienced in omnibuses, and enables the passengers to speak freely to one another. There is a comfortable separate seat to each inside passenger, and much more than the ordinary accommodation for the outside passengers, with ample leg room, and abundance of space to pass. The omnibus, from its peculiar construction, is hung so low that even feeble persons can enter and leave it with the greatest possible ease. The passage room in the centre inside is 6½ft. high, and being 22in. wide between the knees of the passengers on either side, the utmost facility of ingress and egress is presented; and vacant seats can be at once seen for occupation. In plan, the seats are arranged like the teeth of a saw, each presenting a corner to the one on the opposite side. The passengers thus sit at an angle of about 60deg. with the side of the omnibus, and thus obtain a view of outside scenes, instead of gazing into vacancy and each other's faces all the journey.

The steps to the outside are sloping, and very convenient. A screw drag, which is under the command of the driver, enables him to apply it without stopping the vehicle. By its means all weight is taken off the horses in going down a hill. Mr. Harvey's omnibus is somewhat wider, and, in other respects, larger than the ordinary omnibuses, the principal dimensions being as follows:—Extreme length over all from point of shafts to tip of hind step, 21ft. 4½in. Inside measurements of carriage body—length, 14ft. 2½in.; height, 6ft. 5½in; width, 5ft. This omnibus is constructed to carry sixteen passengers inside, and twenty outside, and we understand that three-horse omnibuses under Mr. Harvey's patent, to hold thirty-six or thirty-eight passengers, can be built as light and stronger than the present two-horse omnibuses which carry only twenty-six or twenty-seven passengers.

The trial run with Mr. Harvey's omnibus was accomplished with the most satisfactory results, turning corners of narrow streets and turning round in main thoroughfares with the greatest ease and facility. With regard to the vehicle itself, as a public carriage, we think it superior in every respect to those at present in use. Our experience on the trip was one of comfort and convenience from first to last. There is ample sitting and passage room; each passenger has a seat to himself, and enjoys a look out without twisting his neck—those who sit near the upper end have a clear look out a-head. The noise and rattle are muffled and subdued, so that conversation is conveniently kept up without strain or exertion. There is, however, a slight buzz, which had a singular effect on the tympanum. Our opinion is that this effect is due to the glass—of which there is a considerable amount in the sides of the vehicle—is slightly too thin; a thicker glass would be more rigid, and this sensation, which is slightly unpleasant, would doubtless be removed. With this, and one or two other matters of minor detail attended to, Mr. Harvey's omnibus will be second to none as a public conveyance. With regard to the horses—a point of importance in the working economy—we may observe that they worked excellently well, appearing in no way distressed at the end of the journey. This is highly satisfactory, considering the crowded state of the thoroughfares passed through, and the fact that the omnibus was put through some extraordinary evolutions in the narrow lanes of the City. Of course, there will be an official report, to which we look forward with interest. In the meantime, we wish Mr. Harvey success, and thank him, on behalf of the public, for his practical endeavours to improve that highly useful but highly inefficient institution the omnibus.

THE INSTITUTE OF NAVAL ARCHITECTS.

IF length and multiplicity of matter, with a reasonable clearness of explanation, be sufficient, then Admiral Halstead's paper on the turret and tripod system is second to none. This paper gives the substance of the Admiral's examination, spread over the lengthened period of seven weeks, by the French Imperial Commissioners at Paris. There is no doubt a certain propriety in this local sequence, as with the French "La Gloire" began the race, so hotly contested since, of ironclad ships of war. What we have said in reviewing Sir E. Belcher's paper, we might repeat with emphasis on reading Admiral Halstead's. Ships against guns: guns against ships, is the simple alternation, and may go on, as far as we can see, *ad infinitum*. There is no end to the contest, save the bottom of the purse. The Admiral puts it thus:—

> These necessities gradually resolved themselves into these four propositions, which, it is submitted, must equally apply to any other attempt practically to solve, on a reasonable system, the still pending controversy between armour ships and guns:—1. As in all past battles between ships of wood, so in future fights between ironclads, the respective hostile projectiles must decide, *ceteris paribus*, the issue of victory or defeat. 2. The armour-plate projectiles of the future will decide this issue according to their relative excellence in material, proportions, form, range, accuracy, penetration, and explosive force. 3. These requisite conditions of excellence for the projectiles must rule the conditions for the gun which fires them. 4. These requisite conditions for the guns must rule the mode of turret and turret-ship best able to carry and to fight them.

Here, then, we think we see a gap of sufficient magnitude to swallow £100,000,000 sterling, demanding twenty years, at least, to do it in. Surely, this ought to satisfy any number of hungry expectants of the crumbs that fall from the Admiralty's table. In the combination of seven turrets carrying fourteen guns, commanding nearly the whole sweep of the horizon, no doubt the Admiral has planned a ship most formidable in its character, and probably destructive of any of inferior armament and build. The testimony of such names as those of Coles, Napier, Watts, Lang, &c., leaves no room for doubt on these points. In the proposed combination of turret and broadside guns, the comparative clearness of the upper deck, the gain of a high and dry spar deck, the full equipment for sailing, &c., we see points of surpassing importance proposed. But we quite agree with the Chief Constructor, and Mr. Scott Russell, and others who took part in the discussion, that many of these plans which look well on paper, and perhaps violate no principle theoretically true, may be found unworkable, or even self-destructive; for on both points doubts were expressed by those competent to judge, in the discussion that followed the reading of the paper.

In this discussion we see what a glorious state of confusion we are at present in respecting our navy. No one point seems yet to be fixed as to construction or constructors. Captain Symonds is for fixed central batteries and broadsides; Captain Coles for distributed turrets; and Admiral Halstead for a combination of both. "Let us have long ships," we hear on one side; "Short ships are more handy" meets us on the other. Heavy armour amidships, *a la* "Warrior," is now recommended; now stem and stern and broadside alike, as the "Achilles." By some, rams are said to be most destructive under water; by others, above. Again, it is a question whether our future navy should be designed by sailors or shipbuilders. "Let sailors tell us what they want, and we will let them have it," says Mr. Scott Russell, "but unfortunately we cannot get a sailor to tell us what he wants." Just so; and for the best of all reasons: he does not himself know. For ourselves, we agree with what was said by Sir F. Gray, "that the uncertainty that had hung over the question—What the ships of the future were to be?—since 1856, had not been dispelled. We, therefore, should be careful not to go too fast in building these enormous ships, for we might find ourselves ten years hence with another set of obsolete ships on hand." "Nothing like leather," is the maxim of fools—the warning of the wise. Iron is to do all now-a-days, in defence as in attack, which idea has been so hastily acted upon that now it is a question if our ships will float. Yet the cry is for more iron. If the "plunging" fire is to be adopted (when the ends and sides of ships are no longer pervious to shot) and the decks and bottoms are to be attempted, what remains but that these also must have their 8in. or 10in. of iron plating? The armour can no longer stop at 11deg. of heeling. Now that its weight seems to be bringing our armouring to a dead lock, we

Digitized by Google

hope that more caution and economy will be manifested in the use of public money. We feel confident that in ten years we shall see, as we have said before, that the great models of our ships of war will be the Cunard or the P. and O. packets, the seaworthiness of which would not be very injuriously interfered with by a moderate amount of broadside armouring.

A description of new double expansive engines for H.M.S. "Spartan" was read by Mr. E. E. Allen. Now that steam of such high pressure is coming into general use, the great desideratum for engines is some method of using that steam so as to obtain an approximately uniform motive power. If steam of high pressure is admitted into a cylinder, and there allowed to expand, the work is greatly in excess at the beginning of the stroke, and in defect at the end. This produces great and irregular strains on all parts of the engine, and consequent expense in repairs. The means proposed to remedy this is to allow the steam to expand only partially in the first cylinder it is admitted into, and then to admit it into a second cylinder much larger than the first, where it again expands more fully. The "Spartan's" engines are very ingeniously contrived. The cylinder has an annular projection on its inner surface, through which a hollow trunk works; the extremities of the trunk form pistons which fit the cylinder. The one cylinder in this way is practically divided into four portions, two being annular, and being between the projection on the inner surface of the cylinder and the pistons, the other two being of the ordinary shape, and lying between the pistons and the extremities of the cylinder proper. The steam is first admitted into one of these annular spaces, which are comparatively small, and afterwards into one of the larger spaces outside the double trunk-piston. A very fair uniform motion is thus obtained, and as the steam passages are short, there is little loss of steam in charging them. The use of high pressure steam, and double, or, perhaps, treble or quadruple expansion, combined with the use of liquid fuel, will, we think, soon enable vessels to take a run to Australia or New Zealand, which can now with difficulty reach Gibraltar under steam.

When poor Paddy was commiserated by his mate on the injury sustained by a fall from an elevation, "Oh! sure," says Pat, "it wasn't the fall that hurt me at all, at all, but the sudden stoppage at th'ind." Now, laugh as we may, there was the truest philosophy in the Irishman's answer. The whole difference between the ordinary stoppage of a train, and a railway accident by collision, is accurately measured by the difference of time consumed in the two operations. A fatal and destructive accident is, in this case, wholly caused by the absence of sufficient time to take off the momentum of the train gradually. The buffers of carriages which abut on springs capable of sustaining a pressure of six or seven tons each, afford this gradual diminution of speed, and consequent reduction of momentum, so that we scarcely feel the stoppage of the train. To any one riding in a luggage train, where the trucks are generally without buffers, the difference is not only plainly perceptible, but also inconvenient, and even dangerous. To remedy a similar collision between the consecutive links of chain cables is the object of Mr. Sanders, by whom a paper was read on the application of portable buffers or springs to the cables of ships riding at anchor. Though the case of a railway smash by collision, and the snapping of a cable, may seem different, in fact their causes are identical. In the case of the train, we understand how the catastrophe is caused without further explanation; in the case of the cable, the collision is between the inside parts of any two consecutive links at the points where they touch. The sudden jerk in both cases causes the fracture and its consequences. Now, in a train, we have buffers between each consecutive pair of carriages, and, to make the cases parallel, we ought to have a spring between each pair of touching links in the cable. Could this be introduced, a very small one would suffice for safety. This, however, is impossible, and in this case, the next best provision is made, viz., one large and strong pair of buffers or springs is so applied to the cable as to give the whole and every part thereof the needful relief in case of a sudden strain or jerk by wind or wave. As, according to Mr. Saunders, the spring can be introduced without breaking the continuity of the cable, so that, in case the buffer gives way, the holding is the same as if no application of the sort had been made, we do not see what possible objection can be offered to its use. "The proof of the pudding" in this matter, lies in repeated trials, and, as no evil ensues even on failure, by all means let us so satisfy ourselves of its worthlessness or utility, though the printed testimonials from captains who have used the buffer seem to leave no doubt as to its being able to render very good service.

At the last meeting, on Saturday morning, under the presidency of Dr. Woolley, Mr Merrifield, the indefatigable secretary of the Institution, read an abstract, made by himself, of Admiral Paris's paper on a sea-going turret-ship. It is interesting to receive such contributions of ideas on shipbuilding from "our hereditary foes," and we trust that such fraternal interchanges will go far ere long to change foes into friends in phrase and fact. The French Admiral's object has been so to arrange a monitor as to improve her sea-going qualities, and make her a safe and worthy ocean ship. To effect this, he virtually builds two ships, the one inside the other. The outer ship is very much of the type of the monitor class, broad and low, with its deck little above the water-line. On this deck, at some 9ft. in from the sides, there runs, as it were, the upper part of the sides of another narrower vessel. This construction is intended to secure the decks from being swept, as is the wont of monitors, and also to obtain the more valuable quality of them, viz., the almost entire absence of rolling. This construction also would clearly secure a shallower draught of water for the vessel, which, being fitted with twin screws, would be most valuable for operations near the shore. The lower hull alone is intended to be heavily plated as well as the decks, the upper hull being chiefly appropriated to berthing; the boilers, engines, &c., would all be below. The Admiral would place his guns in a very elevated central battery, to avoid the risks attendant on low ports open in bad weather, and to carry out his idea of the advantage of a plunging fire against ironclads, which are not protected far below the water-line, and not at all on their decks. Unprotected works in a vessel of this construction run fore and aft her whole length, from the central battery, which weak point seems well compensated for in the snugness of the ship, all her weight being concentrated amidships, and her ends quite free from encumbrances of any sort. Given, moreover, a balanced rudder and a ram, and you have the Admiral's idea complete. But the value and risk of the latter is well educed,—the first, by the sinking of the "Rè d'Italia" by the "Ferdinand Max," when the former was at rest and the latter could choose her opportunity; and the second, by the double destruction of the "Osprey" and the "Amazon." The loss of the latter in a couple of hours after its contact with the "Osprey," a mere "cockle shell" in comparison, strongly confirms what we have ventured to express in regard to rams in our comments on Sir Edward Belcher's paper. Notwithstanding that the "Amazon" was a large and strong ship, her bow was by the collision twisted into a position at right angles to her keel. Had the "Osprey" been an armour-plated vessel, what can we suppose but that both would have instantaneously disappeared, proving, if it needs more proof, that the ram is likely to be as injurious to its owner as to her adversary, and that the use of such an armament is much the same as that of knocking one's head against a stone wall. We are very much inclined to believe that after the present mad rush—now to bigger guns and missiles, now to thicker plates to resist them—we shall return, in the main, to the old lines of speed and beauty. Monitors and heavy ironclads may do very well for harbour defence, but the necessity of speed and seaworthiness, which are qualities whereof they are in any great degree innocent, will ultimately drive them out of the market. The contest between our gun and target authorities, each in the heated rivalry crying with the leech, "Give, give," reminds us of the difficulty experienced by the young man from the country in finding an equilibrium between his bread and meat in the cookshop. First, he begged a small piece of bread to balance the surplus meat, and then a bit of meat to equal the surplus bread, till the late-convinced caterer at length kicked the impostor out of the shop. John Bull, the tale has a moral for thee!

The only papers which now remain to be noticed are one by Mr. Mackrow, on the position of the centre of gravity of the Greek armour-clad gunboat "King George," and one by Professor Rankine, on waves which travel along with ships. We will only say a few words on these. Mr. Mackrow's paper included a great deal of arithmetic, which can only be printed in detail. The only point of interest to which we will allude is the experimental method of testing the correctness of the result of the arithmetic which Mr. Mackrow adopted. The gunboat was moored alongside the wharf in Bow Creek, at the top of the tide on a still evening. It was then heeled by means of a couple of armour-plates weighing about five tons each, the angle of heel observed for different positions of the armour-plates, and the position of the centre of gravity deduced from each of the observations so made. The mean of these results was taken, and the result coincided very nearly with the result obtained by the ordinary method. Observation gave 4·373ft. below L. W. L.; calculation, 4·279ft.; the difference being about 1in. Dr. Woolley, who was chairman at the time, hoped that Mr Mackrow's example would be largely followed, and that the time would come when no ship, whether for mercantile or war purposes, would leave a yard without being so experimented on. With this we heartily concur.

The object of Professor Rankine's paper was to show how a certain relation between the depth to which the disturbance of the water extends, and the speed of the wave bears upon the form and motion of waves which travel along with ships. It is not an easy matter to condense this paper, which is one of many able papers which have come from the same pen. The subject, however, is one of interest, and, no doubt, of practical utility. Anyone who has travelled on a steamboat on a broad sheet of smooth water—on the Rhine, or on one of the Scottish lochs, for example—cannot have failed to notice the waves the ship causes, and to observe the curves formed by them. These are the waves discussed in this paper. The Professor thinks it desirable that careful observations should be made of the size, position, and curvature of these waves when raised by vessels of different builds driven at different speeds, to facilitate investigation as to the depth of the original disturbance caused by a ship in still water, and the rate at which the disturbance is transmitted to greater depths. It would be presumption on our part to differ from this opinion.

AERIAL LOCOMOTION.

PHAETON, who, we are told, was so unfortunate a "whip" as to be thrown out of the chariot of the Sun, of which he

Digitized by Google

was allowed to be the Jehu for a single day, and whose sad fate his sisters so deeply bewailed that they were turned into poplars, was evidently a predecessor of the celebrated confraternity of Montgolfier, Godard, Green, and Co., the latter of whom, in one of his excursions, came to grief by being driven—balloon and all—against "tall" trees! and Icarus, who, according to tradition, was able to fly admirably until he got so near the sun that the wax, by which he had attached wings to his body, became melted (so that he, too, met with an untimely death) was evidently the inventor of some primitive parachute. We deem it necessary, therefore, to put scientific men upon their guard, and to point out what appears to us the sensible course to take so as to avoid, on the one hand, foolish attempts to fly, or waste time in floating through the air at the mercy of the winds in a balloon, which, by its shape, is not calculated to navigate the atmosphere; and, on the other hand, to go the right way to work so as to obtain useful and successful results, based on scientific researches, aided and confirmed by calculation and experiment.

To resume and recapitulate our suggestions, then, we propose that a model wind-ship be constructed in the shape of a plover's egg—somewhat elongated fore and aft—either consisting of several inflated bladders, bound together in the manner that we usually suppose the molecules of matter to be united, by which a solid body is formed by a congeries of globular ultimate atoms; or else that a regular wind-ship be built with a light framework, having double sides of leather or gutta-percha, or any other light substance capable of being made air-tight, between whose double skins hydrogen, or any other suitable gas, should be stored; the space in the interior to be of sufficient capacity for experimental requirements, and the whole machine to have sufficient buoyancy to float at any convenient height above the ground. This model air-vessel to be fitted with a sort of horizontal vane, or a kind of continuous float surfaces or fins, by which it would be sustained in the air without losing its horizontality. It might likewise be attached by cables having rings at their extremities, furnished with antifriction rollers, or wheels, so that it might be more or less guided by two parallel ropes, one on each side, in order that it should neither fall entirely to the ground, nor rise a great deal beyond some determined altitude. Such a model air-ship might be worked by hand with a crank in the first instance, or with a spring, for the purpose of trying experiments by which we should obtain data for future operations. But they should be made on some uniform basis—this is most important—for information on such subjects can only be really useful if procured in such a way as that the results of different experiments may be compared one with another. General Morin and the late George Rennie made many interesting enquiries to ascertain the effects or the amounts of friction among different substances, under various circumstances, but, unfortunately, no two experiments have been made with the same units, and comparison between them is therefore extremely difficult, and, in some cases, quite impossible; the consequence is, they are oftentimes entirely valueless.

By following out the plan which we propose, a variety of useful facts could be ascertained, such as the velocities at which a wind-vessel could be forced through the air in certain states of the atmosphere, and against certain currents of air, and also the form or section it should have, so that its "wind-lines" may be most advantageous. Again, how the "float-vane," if we may be allowed the expression, ought to be fixed—whether higher or lower; whether in the form of a spiral, or cycloidal, or parabolical, or segmental curve; whether inclined to the air-vessel upwards or downwards; whether continuous or intermittent; whether horizontally attached or obliquely placed, &c. And, generally, by means of such a model air-ship, many useful preliminary problems might be solved. Again, as to the power best adapted to set the wind traction-engine in motion, experiments might also be tried with such an aerial pontoon and "ropeway." Our idea is, however, as we said before, to make use of some chemical means for compressing air immensely, and then to liberate it, so as to force a piston rapidly through several feet of space, thus driving it against the surrounding atmosphere with great force; in fact, making the air-ship travel on the very principle of the recoil of a gun. In other words, the wind-ship to be moved by a series of recoils or departures from any point, in any direction, with the whole force of immensely and rapidly expanded—not exploded—air, and it would thus shoot itself through space. The motive power would then work in the inverse manner to that of a wind-gauge; instead of the wind acting on it, it should act on the wind. In our opinion, all that is wanted now is enormous power contained in a small space and of very light weight, and to have experiments made in the manner we have described, in order to arrive at the best shape for the wind-ship, the best position for fixing the vane or fins, and the best means of utilizing some of the many chemical combinations we have at our disposal for generating power and compressing air into a very small space, and for suddenly liberating it, so that by the force exerted upon the circumambient air, the aerial locomotive might work its way through the atmosphere. By following up this theory in practice, aerial navigation may become a reality, and many a future Gay-Lussac may make experiments to master meteorological mysteries, without rashly risking life or limb in an unmanageable balloon.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

WAY OF TESTING THE DURABILITY OF COMPOUND METAL SHEATHING—MODE OF FREEZING DECANTERS OF WATER—USES OF NAPHTHALINE—METHOD OF MAKING FLUORIDE OF SODIUM AND PHOSPHATE OF SODA—A NEW MANURE—THE DUKE OF EDINBURGH'S WOUND.

THE compound metal sheathing (mixtures of zinc and copper) applied to ships in place of pure copper is liable to some ill-understood variations. One specimen stands well, while another apparently the same in composition and appearance is so much affected by sea-water that a ship may require stripping after one voyage. Some mode, therefore, of testing the durability of the sheating was desirable, and this has been recently supplied. The inventor takes a sheet of copper and a sheet of the compound metal of an equal size, and places them in a solution of sulphate of copper—the copper plate connected with the negative, and the brass with the positive pole of a battery. Here, it is said, the metal will be exposed to the same conditions as it will be at sea, and if the brass stands well it may be depended upon when applied to a ship. A very feeble galvanic current we fancy should be used.

Every Englishman who has been in Paris brings away with him a recollection of the Carafes Frappées—decanters of frozen water—supplied in such profusion at the cafés and restaurants, and probably often wishes that London was as liberally supplied. A new establishment for supplying them to the cafés has recently been opened in Paris, and the mode in which the water is frozen is said to be as follows:—The decanters, two-thirds filled with water which has been twice filtered, are placed in shallow tanks in which salt water is made to circulate. Each tank contains a copper reservoir with a receiver containing ether. Large air pumps, worked in this establishment by a 16-horse power engine, exhaust the air from the reservoirs, the ether in the receiver boils and passes rapidly away in the state of vapour and the temperature of the salt water, and the water in the decanters is soon reduced to 20deg. below the freezing point. At this temperature, however, the water in the bottle remains liquid; but now a workman goes round and with a glass rod stirs the water in each decanter, and in an instant, "as if by enchantment," it is changed to a mass of ice. At the establishment we notice 6,250 carafes are frozen daily, at what expense is not stated, but it need only be very small.

Naphthaline in a state of fusion dissolves sulphur, phosphorus, the sulphides of arsenic and antimony, and indigo, and deposits them again in a crystalline form as it cools. The crystals may be obtained by dissolving away the naphthaline by means of alcohol. At this time of the year, too, it may be worth mentioning that naphthaline is said to be very useful in driving insects away from plants.

With reference to the fluoride of sodium we spoke of a week or two ago, as an important agent in the treatment of refractory minerals, we find an easy method of producing it at a cheap rate, which may be worth the attention of chemical manufacturers. The inventor of this process, M. Jeannel, roasts fluorspar with sulphate of soda, and carbon (charcoal or coal dust). In this operation fluoride of sodium and oxysulphide of calcium are produced. The former can be dissolved out by lixiviation, but as it is not very soluble, a large quantity of water will be necessary.

In a similar way the same inventor proposes to change phosphate of lime into phosphate of soda. He roasts one part of phosphate of lime with six parts of sulphate of soda, and an excess of charcoal or coal dust. In this case the results are phosphate of soda and oxysulphide of calcium, Phosphate of soda produced cheaply in this way will, the inventor thinks, supersede phosphate of lime as a manure, the solubility of the former being regarded as an advantage. Soda salts, however, are not readily assimilated by plants, and, in some soils, the solubility might be a positive disadvantage. We are inclined to think that the roasted mixture would be employed best without the separation of the phosphate of soda. Oxysulphide of calcium, in the form of "soda waste," has been employed alone as manure with great success. Spread over the ground exposed to air, it is slowly changed into gypsum, which absorbs atmospheric ammonia, the porosity of any residual charcoal contributing to the same effect. On the whole, we are disposed to believe that a compound like the above would be an improvement on "superphosphate."

The dastardly attempt on the life of the Duke of Edinburgh, so happily frustrated by Providence, affords another illustration of the eccentric course taken by balls when reflected from their direct line. In this case, the ball—which was fired, no doubt, obliquely—followed the course of the rib nearly half round the body of the Prince, and rested under the skin. In a similar way a bullet has been known to strike a man in the forehead, and being reflected upwards has passed over the skull and under the scalp, and made its exit at the back of the head. Another still more remarkable case happened in the Crimea, when a grapeshot struck a man in the lower part of the belly and passed out under his knee. In both these cases the patient recovered from the injury, as everyone hopes our illustrious Prince has.

PARLIAMENTARY NOTES.

PARLIAMENTARY proceedings have of late been confined to such purely political discussions as to have left us little or nothing to place on record in our pages. Having, however, during the past week, found various matters of interest to our readers, we have, in pursuance of Captain Cuttle's excellent plan, made notes thereon. And the first thing we noted was, that in the House of Commons, towards the close of last week, the question of coal for the navy was discussed. It may be premised that in the form of tender issued by the Admiralty, for coals to be supplied to her Majesty's dockyards, for the year commencing with the present month, for the use of the steam vessels in the navy, the only coals named are the Welch steam coals. The appropriateness of these coals to

Digitized by Google

the purpose ought to have been sufficient to have vindicated the step. This does not, however, appear to have satisfied Mr. Headlam, or some of his constituents; so he asked why, after the reports made at Devonport, and the recommendations contained therein, as to the use of north country coals in her Majesty's ships of war, these had been excluded.

Lord H. Lennox told the hon. member that the Admiralty had this year reverted to the policy of supplying nothing but smokeless coal to steam vessels in the navy. This decision was arrived at in consequence of the strong representations received by them from the commanders-in-chief of the foreign squadrons, setting forth the great advantages possessed by the smokeless coals for all purposes of steam navigation. He, however, added that bituminous coal was still on the Admiralty list, and was largely used for dockyard purposes. This, we trust, will satisfy the minds of those who can appreciate the step taken in adopting the smokeless coal for steam purposes in the navy, and, at the same time, will not be unsatisfactory to those who were excluded from tendering, by assuring them that they can still hope for a contract for dockyard use.

None who have traversed the "silent highway," or have crossed the Thames either by Westminster or Hungerford-bridges, on the one hand, or by the Victoria-bridge, at Chelsea, or Battersea-bridge, on the other, can fail to have noticed two decided eyesores in the shape of groups of timber piling in the river at either of those points. The first of these nuisances was the subject of a question from Mr. Hardcastle, who asked the Vice-President of the Board of Trade whether there was any probability that the unsightly groups of piling which obstruct the river between Westminster-bridge and Hungerford would be removed; and, if so, when; and whether he could state with whom the responsibility rested. The second gave Lord Otho Fitzgerald an opportunity for asking the same official whether he would reply to the same query with reference to a much more formidable obstruction of the same nature that reached full half-way across the river opposite Battersea-park, and had existed there for a much longer period.

Mr. Cave, in reply to the first question, said the piles were erected by the Waterloo and Whitehall Railway Company under their Act of 1865. The works had been at a standstill since October, 1866, and the directors had stated at general meetings that they were without funds. Their powers expired in July, 1870. They had brought in a bill for extension of time this session, which the Thames Conservators had opposed, and the company had agreed to a provision that all the works on the river should be completed by July, 1870, after which date the Board of Trade or the Conservators might remove the obstructions. With regard to the second question, the obstruction off Battersea-park was the temporary staging of the Albert-bridge. The Act was passed in 1864, and the powers expire in 1869, when the obstruction might be removed in a similar manner. He was afraid the responsibility rested in both instances with the committee which passed the bills. If this be so, the responsibility rests with very irresponsible parties. But the fact of the matter is, that, in both the above instances, the badness of the times has to answer for the non-completion of these works, and, we fear, of many others. The Waterloo and Whitehall Railway works, which were described at page 375 of our issue for June 16, 1865, were begun and continued in good faith, but ended in a collapse for want of funds. This is to be regretted, not only on account of its having left an unsightly row of piling to obstruct the navigation of the river, but because it is an opportunity lost of carrying out a railway upon the pneumatic principle, the details of which have been perfected by Mr. C. W. Rammell, the engineer to the works.

The same remarks hold good with regard to the staging of the proposed Albert Bridge, at Battersea. This bill was only passed after two hard fights in the Houses of Lords and Commons, and the bridge was about to be constructed, when the prevailing disease—impecuniosity—attacked the company or the contractor, or both, and compelled them to stop. It has been stated that the level of the Thames Embankment works not having been fixed at that point was the cause of the stoppage, but we beg leave to doubt that this reason can exist for so long. As in the last case, so in the present, the piling is not the only cause for regret, inasmuch as the new bridge was to have been constructed upon the principle of rigid suspension, invented by Mr. Ordish, the engineer to the works. The designs for this bridge were illustrated and described by us in our issue for January 13, 1865, page 25, and in its non-erection we lose the opportunity of a practical illustration of a sound engineering principle. It is gratifying, however, to know that Mr. Ordish has nearly completed a bridge of large span on the same principle over the River Moldau, at Prague, and which we believe is to be opened during the present month.

Turning from works of peace to those of war, we find next on our notes the old vexed question of fortifications. It relates, however, to that phase of the question which promises either to settle the matter, or to plunge it in still further confusion. We refer to the nomination by Sir John Pakington, as Secretary of State for War, of a committee to enquire into the character and construction of our coast defences, whether of iron, masonry, or earthwork, as recommended by the Royal Commission on National Defences. The committee is to consist of the following officers and gentlemen:—Admiral the Hon. Sir F. G. Grey, G.C.B., chairman; Major-General Collingwood Dickson, C.B., Royal Artillery; Major-General Simmons, C.B., Royal Engineers; Major-General Harness, C.B., Royal Engineers; and Mr. Hawshaw, civil engineer. In the present instance, Mr. O'Beirne asked the Secretary of State for War whether the statement announcing these nominations was correct, and, if so, whether he would state to the House the nature and extent of the instructions under which the members of that commission were to act, what powers had been given to them, whether they were authorized to examine witnesses, and whether he would place a copy of the commission and of the instructions upon the table for the information of the House.

Sir. J. Pakington, in reply, without committing himself to the correctness of the details, stated that he had appointed a committee of the character described. Allegations had been frequently made in the House that the large expenditure on our fortifications and arsenal defences had been to a great extent thrown away. It had been stated that the foundations were in some cases giving way, that in others the walls were cracked, and in others the roofs were falling in, and when he asked on what authority such allegations were made, it proved to be newspaper articles and anonymous letters. It therefore appeared to him desirable to get some authentic information on the subject, and he accordingly appointed the commission. He selected Sir F. Grey to preside over it, because of his known ability and high character, and also because he held the office of President of the Fortifications Committee, and because he had nothing to do with either the designing or construction of the works he would survey. He had associated with Sir F. Grey the officers whose names the hon. member had read, and every one would agree that it was impossible to nominate a commission of higher reputation. He had no objection to lay the instructions given to the commission on the table; they were of the simplest kind; both in them and in his private communications with Sir F. Grey the only point he had insisted on was that in the report of this body of gentlemen, whose honour and competence were above all suspicion, the whole truth should be made known for the information of the House and the country. We trust that the report of this commmission will enable us to reconcile conflicting and contradictory statements, and to set at rest the cavillings and bickerings which have of late been so rife with regard to our fortifications.

A very pregnant question was put by Mr. Whalley when he asked the First Lord of the Admiralty, with reference to the sale of such of Her Majesty's ships as were not now required for the service, whether the use of such ships might be obtained for schools or other public purposes, subject to such conditions for their preservation, and their return when required, as the Admiralty might prescribe.

Lord H. Lennox said the Admiralty had already in many instances given ships for the purposes specified by the hon. gentleman, and would be glad to do so where this was possible and compatible with the public service. At the same time, he must point out that in many cases the societies not only asked for the loan of ships, but required that these should be refitted, caulked, and otherwise repaired at very large cost, for which no provision was made in the Naval Estimates. We do not think that the Government ought to go so far as this. Those who obtain ships for this purpose receive great aid from the State in the loan of the vessel. Therefore, notwithstanding the benefit training ships are to the State, and, notwithstanding also that the object in view is highly charitable, we think the borrowers should be content with the ship, and look after her repairs themselves. Our Navy Estimates are quite heavy enough without the addition of items which properly fall within the province of public philanthropy to meet.

THE WHITWORTH SCHOLARSHIPS.

WE have been requested to give insertion to the following letter and resolutions relative to Mr. Whitworth's recent munificent benefaction, which we recorded in our impression for the 9th ult.:—

THE INSTITUTION OF CIVIL ENGINEERS,
25, Great George-street, Westminster, S.W.,
May 2, 1868.

SIR,—At the moment when it is considered by many, that more systematized methods of instruction are necessary for those intended to follow industrial and scientific pursuits, you, sir, come forward with the best practical help that could possibly be devised. In the learned professions numerous forms of endowment already exist; but for all those occupations which are intimately associated with the applications of pure science to the affairs of every-day life, hitherto there has been no such encouragement.

I have the greatest pleasure in being the medium of conveying to you the accompanying extract from the Minutes of the Institution of Civil Engineers; and I am sure that the general feeling of your brother members is, that any words very inadequately express the sense of their indebtedness for your princely liberality.

I am, Sir,
Your obedient humble servant,
JAMES FORREST,
Secretary.

To JOSEPH WHITWORTH, ESQ., F.R.S.,
M. Inst. C.E., &c., &c., &c.

At the Ordinary General Meeeting of the Institution of Civil Engineers, held on Tuesday, the 28th of April, 1868, Mr. Charles Hutton Gregory, the President, being in the chair, the following communication from the Council was brought forward, was adopted by acclamation, and a copy ordered to be sent to Mr. Whitworth:—

"Attention having been called to the foundation in perpetuity, by Mr. Joseph Whitworth, M. Inst. C.E., of Thirty Scholarships, of the annual value of £100 each, for the instruction of young men, natives of the United Kingdom, to be selected by open competition for their intelligence and proficiency in the theory and practice of mechanics and the cognate sciences, with a view to the promotion of engineering and mechanical industry in this country, it was

"Resolved unanimously,—That this meeting desires to record, on its own behalf, and on that of the members of all classes of the Institution of Civil Engineers, its grateful recognition of this act of munificence, and its high appreciation of the services which have thereby been rendered to the cause of technical education and national advancement, and of the advantages that may be expected to accrue, alike to the profession and to the community generally."

Signed on behalf of the Institution of Civil Engineers. JAMES FORREST,
Secretary.

SOCIETY OF ENGINEERS.

AT the meeting of the Society of Engineers, held on Monday the 4th inst., Baldwin Latham, Esq., President, in the chair, it was unanimously resolved, "That the thanks of the Society be conveyed to Mr. Whitworth for his munificent endowment of thirty free scholarships for the engineering profession." The following candidates for election were balloted for, and duly elected as members:—Messrs. E. D. Latham, Borough engineer, Bideford, Devon; G. B. Ritchie, resident engineer, London and North-Western Railway, Leighton Buzzard. As Associate—R. J. Cheeswright, Clerk to the Croydon Board of Health, Town Hall, Croydon. It was announced that the council had made arrangements for the members to visit various public works during the coming vacation. The meeting was adjourned to Monday, October 5.

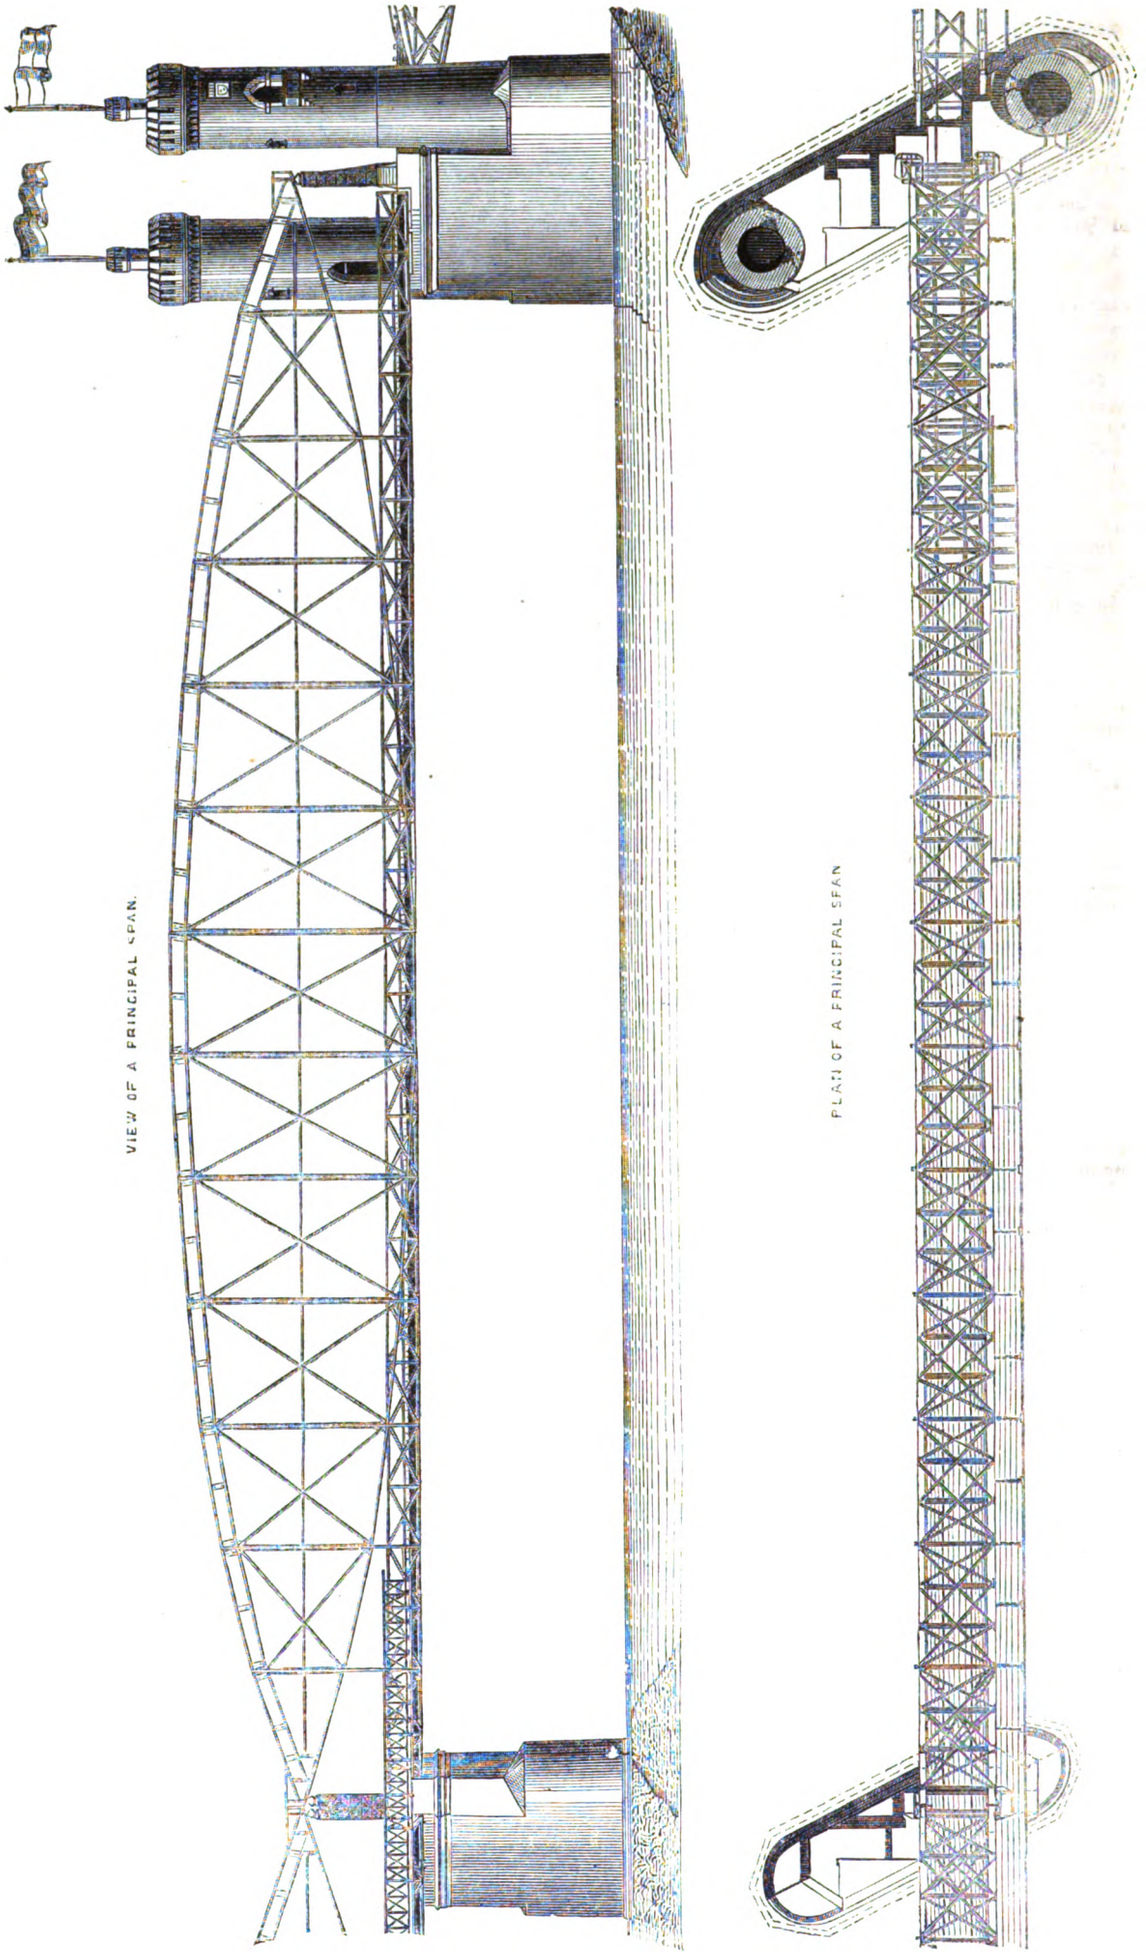
BRIDGE OVER THE RHINE, AT MAINZ.



Digitized by Google

BRIDGE OVER THE RHINE, AT MAINZ.

TWO lines of railway leave the station at Mainz; one crosses the Rhine, and so forms the junction at Mainz of the Gustarsburg-Darmstadt line with the other line which runs from Mainz to Worms. The communication across the Rhine is effected by means of a bridge of different spans, of a total length, width of intermediate piers included, between end piers of 1028·645m. In order not to hinder the navigation on the Rhine, and to interfere with the laws agreed upon for its protection by the Rhine States—Baden, Bavaria, Hesse, and Prussia—the bridge was to be built 14·10m., or about 48ft., above low-water mark, thus rendering the height of the platform 15·1m., or over 49ft., above low-water. Owing to these circumstances the line on one side from the station at Mainz rises by a gradient of 1 in 80 for a length of about 708m. The bridge crosses the river in an oblique line, making an angle with the stream of 27deg. The requisite width of the Rhine, as fixed by commissioners of the Rhine States, for the navigation is 360m., thus requiring four spans of 90m. each, measured at right angles to the current; but as the bridge crosses the river in an oblique line the width of the spans was increased to 101·29m., or about 326ft. each, not including the thickness of the piers.

On the right side of the river the line descends again on an incline of 1 in 74, in order to reach the ordinary height of the embankment. The length of this incline to the embankment is taken up by six flood openings of 33·5m., and thirteen openings of 15m. each; two openings of 25m. each; and, lastly, seven openings of 15m. each, thus giving a clear width of the bridge of 956·56m., or, including the thickness of the intermediate piers, a length of 1028·645m. from abutment to abutment. Our engraving shows one of the principal spans, and a portion of one of the flood openings of this bridge. The principal piers are 4·25m. thick at the top, and increase towards the bottom at the rate of 1 in 30. The next, on the right side of the river, is 5·9m. wide, and is ornamented with two towers corresponding with those on the Brackenkyof at the opposite side. The piers of the flood openings are each 2·35m. thick, and those on the thirteen following openings 1·75m. each, and the remaining six 1·25m. each. The foundations in the water are made of beton, and are 10in. wide, and guarded by timber piling of 1ft. in thickness, and secured further by large stones thrown around them. The piers themselves are built of sandstone blocks. The foundations or piers are made for two lines of rails, but only one is executed as yet.

All the upper construction is made of wrought iron, on the principle known as the *systeme Pauli*. The iron construction of each span consists of two main girders of the (lextil) shape peculiar to the system. To these main girders the strains are transmitted from the roadway by means of a system of longitudinal cross girders, tie bars, &c., and from them are taken up by the piers. Each main girder consists of an arched top flange, which is subjected to compression, and of the lower flange of a shape corresponding with the top flange, but bent in the reverse direction. This flange has to resist tensile strain. These two flanges are connected by vertical columns and crossed tie bars. With the columns the parts forming the platform are united, and consequently only at these joints the transmission of the strains to the main girders is effected. All the joints are arranged in such a manner that the transmission of the strains only takes place, so that the material is disposed only in the direction of the strain; no part, therefore, is subjected to bending force. For this reason the cross tie bars of the main girders have been made very thin as compared with their breadth, so that they are quite unable to act as struts.

There are two such cross tie bars between every two vertical columns, so that by any eccentric load the one of them is exposed to tension, whilst the other, on account of its being unable to resist compression, is bent by the displacement which is caused by the load. The top and bottom flanges of this system, as by any other girder of one opening only, are subjected to compression or tension only respectively. The girders rest on shoes at each end, provided with steel plates; the shoes on the one side of the girder are fixed, whereas those of the other side are provided with rollers in order to allow for movements caused by the change of the temperature. The rails rest on wooden sleepers supported by longitudinal plate girders, which repose on lattice cross girders, through which the load is transmitted at the connecting points with the vertical columns to the main girders. The cross girders are at right angles with the main girders, which, therefore, had to be made 105·2m. long from support to support.

SCIENTIFIC RATCATCHING.

ACCORDING to the French "Moniteur" there are in France upwards of two thousand millions of rats and other rodents. Supposing each of these little quadrupeds to commit the damage of only one centime per annum, this loss would amount in the aggregate to twenty millions of francs annually. Hence it is most desirable to find some means of destroying this vermin in large numbers as expeditiously as possible. Nux-vomica, arsenic, phosphorus, and traps have been successively tried, but with no very decided success, and certainly not equal to the rate of increase of these prolific creatures. Recent experiments, however, show that squills (Scylla maritima), the enormous bulbous root of which is much used in medicine, is not only a powerful poison for rodents but also one they are very fond of. The way of preparing it for the desired purpose is as follows:—One of the bulbs is cut into slices, hashed and bruised, then done in the pan with fat, which is afterwards strained through a cloth and poured into broken plates and saucers to be placed in the cellars and other places infested with rats, mice, &c. To prevent dogs and poultry from eating of this poisonous compound in stables, pigeon-houses, or farmyards, it may be put into a wooden box about 1½ft. long, and having a hole at each end. The rat gets in at one end and goes out at the other, after partaking of the noxious food, which soon kills it. Squills may also be reduced to powder for the same purpose by bruising them in a mortar to a pulp, which is afterwards incorporated with as much flour as it will hold. This paste is then rolled out, as they do for a pudding, then cut into shreds, which are left to dry on hurdles or on sheets of pasteboard, and are afterwards pounded in a mortar. The powder thus obtained will keep for years, and may be put into boxes or barrels. If manufactured on a large scale it may become a profitable article of exportation. In Algeria squills cost nothing, the country being absolutely overrun with them. They have a different notion of dealing with the question in America, where a correspondent of the "Scientific American" recommends the following method of catching rats in a cheap and effectual manner:—Cover a common barrel with stiff, stout paper, tying the edge around the barrel; place a board so that the rats may have easy access to the top; sprinkle cheese parings or other food for the rats on the paper for several days, until they begin to believe they have a right to their daily rations from this source. Then place in the bottom of the barrel a piece of rock about six or seven inches high, filling with water until only enough of it projects above the water for one rat to lodge upon. Now replace the paper, first cutting a cross in the middle, and the first rat that comes on the barrel top goes through into the water and climbs on the rock. The paper comes back to place and the second rat follows the first. Then begins a fight for the possession of the dry place on the stone, the noise of which attracts the rest, who share the same fate.

THE GUNBOAT "STAUNCH."

WE this week devote a good deal of space to illustrations of a very small craft; and we have good reason for doing so, for, insignificant as the little "Staunch" may seem, she is the first practical embodiment of a very valuable principle. In all attempts which have hitherto been made to provide naval defences for our seaports the favourite idea has been to resort to the use of monitors, because they can carry excessively heavy guns and offer a very small mark for hostile shot. Now, both these advantages would be possessed by gunboats of small size mounting one gun each—floating carriages, in fact—but they are accompanied by drawbacks so great that gunboats enjoy small favour. Their defects are that if of little tonnage they cannot carry a heavy gun as deck load in bad weather or a rough sea, and therefore they cannot with any safety proceed from port to port when it blows hard. Thus, if an attack on Holyhead were threatened, gunboats of the ordinary construction could not proceed there from Liverpool for its defence. Even such gunboats as we have of the "Earnest" class, although of considerable size, and mounting only a 56cwt. gun, are of little or no value in a gale.

Fully convinced of the value of a seaworthy fleet of gunboats little larger than the launch of a line-of-battle ship, Mr. G. Rendel, of the firm of Sir W. Armstrong and Co., of Elswick, set about producing a model boat some time since which should be free from the defects of previous gunboats. The result of his labours is the "Staunch," which is in almost every respect perfectly novel. The "Staunch" is 79ft. long, 25ft. beam, and has a loaded displacement of 150 tons, and a mean draught of 6ft. She carries the largest gun ever put on board such a craft—an Armstrong 12½-ton rifle. This gun is supported on a platform carrying the slide. The platform is provided at each corner with a screw box working on one of four columnar screws rising from the floor of the forehold. All the screws are driven simultaneously in the same direction by a donkey engine through gearing, the construction of which will be understood by a glance at our engravings. When proceeding to sea, the screws are made to revolve and lower the gun into the forehold, where it is carried as cargo. When going into action the donkey engine is put in motion and the gun screwed up on deck in about eight minutes, the same time sufficing to lower it again. As the gun is in line with the keel, rolling on the part of the boat does not affect it. A screen of thin plates sufficient to keep out rifle shot is constructed across the bows of the little vessel, which is otherwise unarmoured. Side tackles are used for working the gun, but instead of the ropes being hauled on by a large gun's crew, a turn is taken with them by one man on each side of the gun round capstan heads revolved by the machinery below, each man tightening the rope's end. Friction is caused against the surface of the capstan head and the rope is drawn forward, and the gun run out or in, as the case may be. In the same manner the shells are run up out of the shell-room below, and other work done, tending greatly to reduce the number of the crew. On trial it has been found that even when rolling 11deg. the gun can be raised and lowered with ease. No provision is made for training the weapon, because all lateral movements are effected by the use of the rudder, the steersman standing, as will be seen, close to the rear of the gun. In order that the fullest effect may be given to this principle, the "Staunch" is fitted with twin-screws driven by engines of the collective nominal power of twenty-five horses.

There are two cylinders to each pair of engines, 14in. diameter and 14in. stroke. One air pump is fitted to each pair of engines, cast with the condenser and forming so far the framing of the engine. Each air pump is 12in. diameter and 7in. stroke, worked from the crank shaft by an eccentric placed in the centre. One feed and one bilge pump are provided for each pair of engines, each 3in. diameter and 4in. stroke, worked by back gear eccentrics. The propellers have three blades, are 5ft. diameter and 7ft. pitch. Steam is supplied by one boiler, shown in our engraving, with two furnaces and 138 brass tubes, and a heating surface of 700 square feet. The total area of the fire-grate is 27 square feet. The boiler also supplies the engine for working the gun. On trial the engines made 150 revolutions per minute, the working pressure in the boiler being 25lb. per square inch, and the vacuum 27in.; indicated horse-power 130. The engine and machinery for working the gun were designed by Mr. G. Rendel, and were manufactured at the Elswick Engine Works, Newcastle-on-Tyne. The screw engines were designed and manufactured by Messrs. Robert Stephenson and Co., and on the trial trip gave perfect satisfaction, working without heating. They are very favourable specimens of their kind. The hull was built by Messrs. Mitchell, of Low Walker.

It might be supposed that although a heavy gun can be carried in such a little craft, it cannot be worked with full charges, but the contrary is the fact. A very large number of rounds have been fired with full charges of 56·25lb. of powder and 285lb. shot. As regards the "Staunch's" power of making evolutions, it will suffice to say that during the recent trials with the engines driving reverse ways, the vessel made the full circle in her own length in 2¾min. With both engines going full ahead, she made by the helm a complete circle of 75yds. diameter in 2¼min. At a moderately close range the most powerful ironclad we have afloat, excepting perhaps the "Hercules," could be pierced at every round by the "Staunch's" gun, and as she would be very hard to hit in a fair sea—and could not well be run down because she is so lively—she would constitute, even alone, a formidable antagonist. But a fleet of thirty or forty "Staunches" would prove too much for any three or four ironclads in the world, and yet such a fleet would cost less than one large armoured war ship, and would be capable of manœuvring in shallow water where larger ships could not follow them. Let us hope that the principle will meet with all the consideration it so well deserves at the hands of the authorities who have now the "Staunch" placed at their disposal for trial.—"The Engineer."

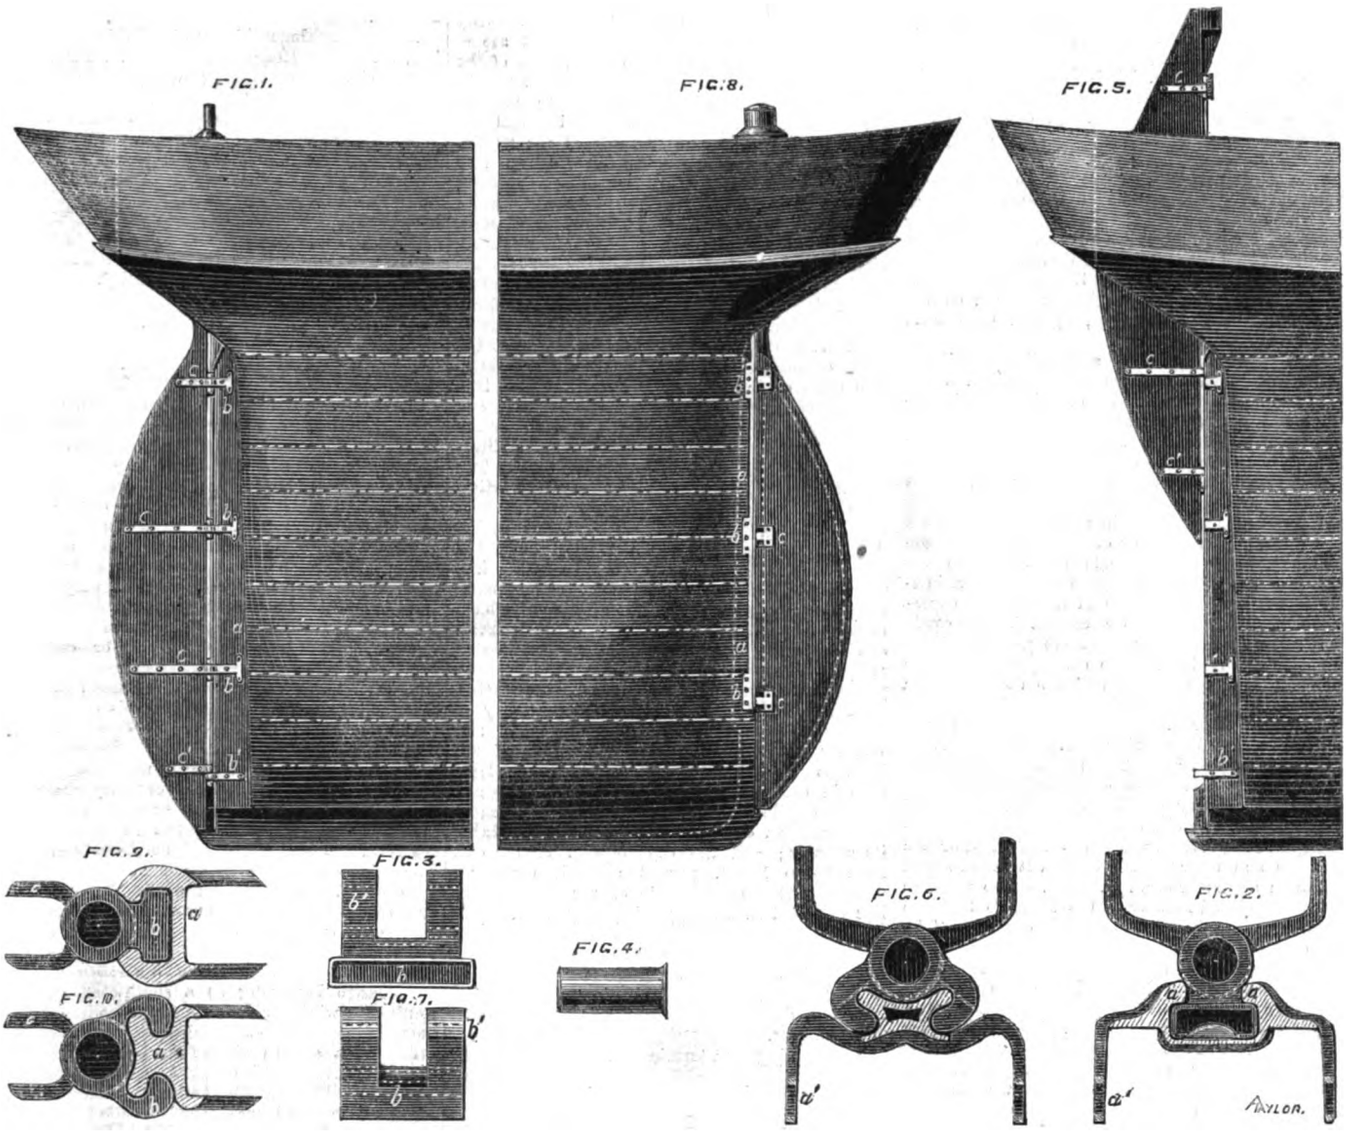
THE SLIDING RUDDER.

BY MR. J. MEDHURST.



THE SLIDING RUDDER.

SOME sure and safe mode whereby the rudders of ships may be unshipped and shipped for repairs when at sea is much needed, many disasters having occurred in consequence of ships' rudders breaking and becoming useless. We, therefore, have much pleasure in placing before our readers engravings and description of a sliding rudder, the patented invention of Mr. John Medhurst, of No. 70, Mark-lane, London. Mr. Medhurst fixes at the stern of the ship a rudder trunk of such a size that the rudder can be raised up on to the deck through it and afterwards again lowered into its place, and in place of fixing the braces or the sockets which receive the pintels of the rudder to the stern post, as is usual, he makes them capable of moving up and down a guide fixed on the stern post. This guide is a casting or forging fixed to the stern post and with a dovetailed or undercut groove in it, and the braces are formed so as to fit into this guide and be securely held by it. The pintels and braces are so arranged that they cannot escape the one from the other. They form with each other ordinary hinge joints. In our engraving, fig. 1 is a side elevation of the stern of a wooden ship fitted with a rudder in the manner we have described. *a a* is a metal casting which is accurately fitted to the stern post of the vessel and secured to it by bolts passed through the lugs a^1 a^1 of the casting. This casting has a dovetailed or undercut groove formed in it from end to end, as is seen in fig. 2, which shows to a larger scale a transverse section of the casting and parts connected therewith. The groove in the casting is very slightly tapered, increasing in size from the bottom upwards; *b b* are the movable braces—they fit the groove in the casting accurately each in its proper position, and from the groove of the casting being tapered when they are lifted from their seats they are held sufficiently loosely in the groove to move easily along it. A side view of one of the braces *b* is shown at fig. 3; it is made with two eyes b^1 b^1, which receive between them a corresponding eye with which each of the rudder pintels *c c c* is furnished. Fig. 4 is a side view of the pin which holds the braces and pintels together and forms with them a hinge joint; the pin has a small head at its upper end which prevents it falling through when it is put into its place. The braces *b b* and pintels *c c* are put together before the latter are secured to the rudder to which they are correctly fitted and firmly secured by bolts passing through the lugs or straps formed on them.

A dotted line in fig. 2 shows the form to which the woodwork of the rudder is fashioned; it is such as produces a nearly flush surface with the outside of the pintels and their eyes, so that the hinge pins cannot work up out of their places. The lowest brace b^1 is fixed to the stern post, as has heretofore been the custom, and the lowest pintal c^1 of the rudder is also of the ordinary form, so that the casting *a* may terminate immediately under the third pintel of the rudder when in position. The weight of the rudder is taken by the brace b^1 assisted by a dumb cleat fixed to the stern post on which the pintel c^1 of the rudder rests. When the rudder trunk is deep, as may be the case in a vessel having a full poop, the guide groove for the movable braces is continued above the casting *a*, it is best formed in the stern post, the wood being cut away, and the groove being lined with sheet metal.

Fig. 5 is a side elevation of the stern of a ship corresponding with fig. 1, but here the rudder is shown in process of being lowered into its place through the rudder trunk. In this operation the rudder is hauled by tackle into an upright position over the rudder trunk and carefully steadied by guy ropes. It is then gradually lowered, and the braces in succession entered into the guide groove in the stern post. In order to fill the guide groove in the casting *a* to keep it clean and prevent the adhesion of marine animals and vegetables, cakes of tallow and stearine, cast to form and cut off to the lengths required, are used. These cakes are entered into the guide groove between the braces as the rudder is lowered. These cakes, however, are unnecessary where the groove is not of iron. Fibre, such as coir or other cheap fibre, is mixed in with the tallow and stearine so that the cakes do not readily break or crumble. In order that the rudder may not rise when struck by a sea, a turned metal ring is shrunk upon its head at the level of the deck. Over this ring an exterior ring is fitted, which at the bottom has a flange on the outside by which it is bolted down to the deck, and at the top an internal flange overlapping the upper end of the ring on the rudder head; this flange ring is bolted down after the rudder has been shipped, and it is removed prior to unshipping it.

It is not essential that the guide fixed to the stern post, to lead the braces to their position, should be of groove form: it may be a projecting guide, and fig. 6 shows a transverse section of such an arrangement; in this case the braces *b b* are made with horns to embrace the guide. A side view of one of these braces is shown at fig. 7. Fig. 8 is a side elevation of the stern of an iron ship fitted according to Mr. Medhurst's invention. The guide *a* on the stern post is here made of iron, either a forging or a malleable casting, and it is riveted to the iron stern post. A transverse section through this piece *a* is shown at fig. 9, and the corresponding braces *b* and pintels *c* are also represented. In iron ships also the projecting guide may be substituted for the guide groove, as is shown in the transverse section fig. 10.

It will thus be seen that this invention is one of a highly practical character, and of great value to the shipping interest. We are glad to learn that they are appreciating it, for we are informed that Mr. Medhurst's rudder has been applied to vessels in the West India trade, to the great satisfaction of their owners. Messrs. Oswald and Co., of Sunderland, are, we understand, applying the principle to a large ship now in course of construction by them.

INSTITUTION OF MECHANICAL ENGINEERS.

THE general meeting of the members of this Institution was held on Thursday, April 30, in the lecture theatre of the Midland Institute, Birmingham, Thomas Hawksley, Esq., Vice-President, in the chair.

The Secretary (Mr. W. P. Marshall) read the minutes of the previous meeting, and a number of new members were elected. A communication from the Patent-Office was read, requesting the nomination of gentlemen by the Institution, for the appointment to be made by Government of one out of three additional Commissioners of Patents; and Mr. Charles Edward Amos, of London, and Mr. Robert Charles May, of London, were nominated by the meeting for this purpose.

The adjourned discussion then took place upon the paper read at the previous meeting, on the Allen engine and governor, by Mr. Charles T. Porter, of Manchester.

The next paper was a description of the American dovetailing machine, by Mr. John Robinson, of Rochdale. This machine, the invention of Mr. T. S. Armstrong, of New York, was shown at work at the recent Paris Exhibition; and it is constructed so as to cut out the dovetail joints in woodwork by means of the continuous rotation of compound circular saws of peculiar form, which finish the joints completely, without the use of any chisels or cutters. The same machine cuts both the pins and the holes of the dovetails in succession, by a simple change of adjustment, so that their pitch and dimensions correspond exactly, and make a correct joint in every case. The two circular saws are placed inclined to each other at an angle corresponding to the inclination of the two sides of the dovetail pins; they are geared together by two bevelled toothed rings upon their inner faces, and the first saw is driven by bevelled gearing from the main driving shaft of the machine. The two inclined axes of the saws are themselves capable of being rotated simultaneously by gearing through a quarter of a revolution, whereby the direction of their inclination is changed from vertical to horizontal or the reverse, and their point of contact is rolled round through a quarter of a revolution. The wood to be cut is placed radially to the saws, so that the cuts are at right angles to the face of the wood in cutting the dovetail holes, but inclined towards each other, one saw cutting the right-hand side and the other the left-hand side of each hole. By then rotating the axes of the saws through a quarter of a circle, the dovetail pins are cut, with parallel sides on the face of the wood, but inclined on the edge of the wood; and by this means the pins and holes are formed at exactly the same inclination, by the simple expedient of cutting them at two different points of the circumference of the saws, at right angles to each other. Each saw cuts one-half of a pin or hole in a single revolution; the first three-quarters of the circumference of the saw blade is made plain, like an ordinary circular saw, but with a spiral outline gradually increasing in diameter, so as to increase the depth of cut until the bottom of the dovetail is reached; and then the last quarter circumference of the saw blade is made truly circular, but has the cutting edge bent over at right angles, so as to cut at the side, for cross-cutting the bottom of the dovetail; the lateral projection of the flanged blade gradually increases until it is equal to half the width of the bottom of the hole. The blade of each saw, instead of being at right angles to the axis upon which the saw revolves, is set inclined like a screw thread, with the pitch equal to the intended pitch of the dovetails; and the wood is traversed across the saws by a bed screw of the same pitch, so that each saw follows up its own cut correctly to the end of the revolution, and then begins a fresh cut at the proper distance for the next dovetail. In order to take up the slack that would be caused in the fit of the dovetails by the thickness of the saw-cuts themselves, each saw is turned upon its own axis through a small arc, at the time of changing from cutting pins to cutting holes, and is then secured in the position marked: the fit of the dovetails is thereby readily adjusted to any degree of tightness that is required. Also, by giving to the table on which the wood is fixed an inclination of 45deg. to its usual radial position, the same machine serves for cutting concealed dovetails, in which the two pieces of wood form a mitre at the outer angle. The saw blades are made in short segments, held by screws in a turned recess in the boss of the saw; and they are readily and quickly changed when it is required to set the machine for cutting a different size of dovetail. Specimens were exhibited of dovetails cut by the machine, together with one of the saws employed for the purpose.

The last paper was on an improved cupola for iron foundries, by Mr. J. Eichhorn, of London. In this cupola, which is the invention of Mr. Henry Krigar, of Hanover, the objects aimed at are to concentrate the heat in the lower part of the furnace, and render the action uniform throughout the operation of melting, and to prevent the blast from injuring the heated metal by oxidizing it. The vertical shaft of the cupola, which is made rectangular in form, opens into a lower chamber, the bottom of which forms the hearth to receive the melted metal. Round the bottom of the shaft runs an air passage, into which the blast is delivered from the air main; and the blast entering through this passage cools the brickwork of the cupola, and becomes heated itself; it then passes down into the melting chamber of the cupola through two long slots in the roof, one at the front and the other at the back, extending the whole breadth of the hearth. The front of the furnace is closed by an iron door on hinges, extending the whole breadth, and lined with clay and sand on the inside; and a smaller door is placed at the back, to facilitate the drawing of the furnace after each heat. The cupola is charged from the top of the vertical shaft in alternate layers of coke and iron, as usual, a filling of coke being first put in for starting, before closing up the front door. In the working of the cupola, the coke falling into the melting chamber from the vertical shaft stands there in a heap, upon which the blast rushes through the two transverse slots in the roof: and the heat from the burning fuel being radiated into the air passage, the blast becomes prepared for combining rapidly with the carbon of the fuel, before it has an opportunity of coming in contact with the melting metal and wasting it by oxidation; and the action of the blast is finished at a considerably lower level than in ordinary cupolas. The metal obtained in this cupola is found to be very fluid, more so than in an ordinary cupola, while retaining its softness; and the consumption of coke is from 1¼ to 1½cwt. per ton of iron melted, according to the magnitude of the charge, the loss of metal in melting being only from 2¼ to 3½ per cent.

It was announced that the annual meeting of the Institution in the ensuing summer would be held at Leeds, on Tuesday, July 28, and following days, during the time of the Art Exhibition in Leeds.

The meeting then terminated.

ROYAL INSTITUTION.

AT the annual meeting of the Royal Institution of Great Britain held on Friday, May 1, 1868, W. Pole, Esq., F.R.S., in the chair, the annual report of the committee of visitors for the year 1867 was read and adopted. The books and pamphlets presented in 1867 amounted to 131 volumes, making, with those purchased by the managers, a total of 319 volumes added to the library in the year, exclusive of periodicals. Forty new members were elected in 1867. Sixty-three lectures and twenty evening discourses were delivered during that year. Thanks were voted to the president, treasurer, and secretary, to the committees of managers and visitors, and to the professors, for their services to the Institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—President—Sir Henry Holland, Bart., M.D., D.C.L., F.R.S.; treasurer—William Spottiswoode, Esq., M.A., F.R.S.; secretary—Henry Bence Jones., M.A., M.D., F.R.S.

Managers:—Henry Wollaston Blake, Esq., M.A., F.R.S.; Charles Brooke, Esq., M.A., F.R.S.; Adm. Sir Henry John Codrington, K.C.B.; Captain Douglas Galton, C.B., F.R.S.; John Peter Gassiot, Esq., F.R.S.; William Robert Grove, Esq., M.A., Q.C., F.R.S.; Cæsar H. Hawkins, Esq., F.R.S.; Sir John Lubbock, Bart., F.R.S. Pres. Entom. Soc.; Sir Roderick I. Murchison, Bart., K.C.B., D.C.L., F.R.S.; William Pole, Esq., M.A., F.R.S.; William Frederick Pollock, Esq., M.A.; Robert P. Roupell, Esq., M.A., Q.C.; Lieut.-Gen. Edward Sabine, R.A., D.C.L., Pres. R. S.; Sir Charles Wheatstone, D.C.L., F.R.S.; Colonel Philip James Yorke, F.R.S.

Visitors:—Andrew Whyte Barclay, M.D.; Charles Beevor, Esq., F.R.C.S.; John Ashton Bostock, Esq.; John Charles Burgoyne, Esq.; Rev. Charles Fynes Clinton, M.A., F.R.G.S.; Alfred Davis, Esq.; William Dell, Esq.; Rev. G. Godwin Pownall Glossop, A.M.; Alfred Gutteres Henriques, Esq.; Edward Henry Moscrop, Esq.; William Newmarch, Esq., F.R.S.; Arthur Giles Puller, Esq., M.A., F.S.A.; Samuel Scott, Esq.; Edward Owen Tudor, Esq., F.S.A.; Robert Ballard Woodd, Esq., F.S.A., F.R.B.S.

At the general monthly meeting, held on Monday, last, Sir Henry Holland, Bart., F.R.S. President, in the chair, the following vice-presidents were nominated for the ensuing year:—W. R. Grove, Esq.; General Sabine; Sir Charles Wheatstone; William Spottiswoode, Esq., F.R.S., the treasurer; William Anderson, Esq., LL.D.; Captain N. D. C. F. Douglas; Frederick Green, Esq.; Swann Hurrell, Esq.: John Edward Taylor, Esq., were elected members. The following professors were re-elected:—John Tyndall, Esq., LL.D., F.R.S. as professor of Natural Philosophy; Edward Frankland, Esq., Ph.D. F.R.S. as Professor of Chemistry.

SIGNS OF STORMS.

THE following observations on storms, and instructions respecting them, have just been issued by the Meteorological Committee. The ordinary signs of coming atmospherical disturbance are sudden increase or decrease of atmospherical pressure, as shown by the rapid rise or fall of the mercury, or the hand of a barometer, great difference of pressure between adjacent stations, and sudden changes of temperature. If the weather, especially in winter, be very warm and damp for the season, there is danger of a storm; if the wind "backs" instead of "veering," the weather is likely to become or continue bad. N.B.—The wind generally changes with the sun, *i.e.*, a north wind changes to south through east, and so on; any change in this direction is called veering; a change in the direction from north towards south through west is called backing, and occurs when weather is unsettled.

A few remarks as to the ordinary character of winds and storms may be of use. The winds which are most commonly felt in these islands are from the south-west and north-east quarters. The south-westerly wind blows most frequently; it is called the equatorial current, and is warm and moist. While this current is blowing, the barometer is low, and the weather cloudy, and often wet. The barometer falls when a south-west wind is about to succeed a north-east wind; the change beginning as a south-east or south-south-east wind, which lasts for some hours with heavy rain. South-west gales are frequently preceded by a sudden rise of the barometer; however, this movement is checked, and the barometer begins to fall before the south-east wind begins to blow. The north-east wind is called the polar current, and is cold and dry. While this current is blowing the barometer is high, and the weather usually clear and dry. The barometer rises when a north-east wind is about to succeed a south-west wind; the change beginning as a north-west or north-north-west wind, which is frequently in winter accompanied by a fall of snow.

The storms which are felt on our coasts are generally south-westerly storms, during which the wind may blow from any point between south-east, round by south, to west and west-north-west. In winter, after a prevalence of easterly winds, if the barometer begins to fall, and the thermometer to rise, a gale which commences to blow from south-east will veer to south-west, while the barometer falls constantly. As soon as the wind passes the south-west point, the barometer begins to rise, a heavy shower of rain falls, and a strong west-north-west or north-west wind may follow, after which the sky clears, and the weather becomes colder. In some rare cases this north-west wind may be followed by a north or north-east wind. If the wind "backs" from the north-west towards west and south-west, and continues strong, the bad weather is almost sure to continue.

Most of these gales are felt first on the west coast of Ireland, and, subsequently, at stations lying to the eastward. Accordingly, if the change of direction of the wind takes place rapidly, the storm may be blowing from north-west on the coast of Ireland, while it is only commencing to blow from the south or south-south-east on the east coast of England. Such gales are very violent, and being produced by a south-west (equatorial) current which is forcing its way against a north-east (polar) current, the alternations of pressure and temperature are very rapid, and the storms are frequently accompanied by thunder and lightning.

Digitized by Google

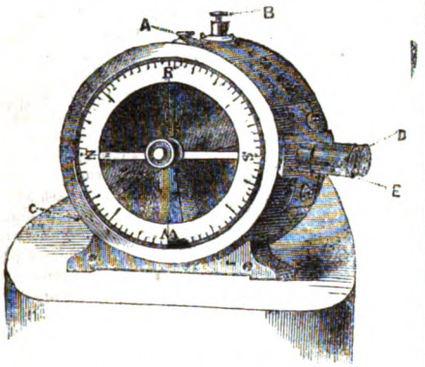
North-easterly storms are not so frequent as those from the south-west. They are very dangerous on the east coast of Great Britain, as they do not give so much warning of their approach as south-west gales, nor can intelligence of them be sent from distant stations so easily.

hey are generally preceded by a low temperature for the season. They frequently begin with a north-west or north-north-west wind, and with a heavy fall of snow; the sky soon clears, and the wind blows hardest from north-east. These polar (north-east) storms do not veer to the same extent as the equatorial (south-west) winds; they very seldom change their direction more than two or three points, while a shift of wind with the sun through six or seven points is very common in the case of equatorial (south-west) storms.

CASELLA'S POCKET ALTAZIMUTH.

THIS elegant and useful little instrument, for travellers especially, is, we are informed, the invention of Mr. Casella, philosophical instrument maker, Hatton Garden, but has been modified and improved by F. Galton, Esq., F.R.S. By its means altitudes, azimuths, bearings, levels, and gradients are obtainable. It is strong, handy, and portable, its diameter being 2¼in., thickness 1in., and weight about 5oz. The following is a description of the instrument, for which, together with the accompanying engraving, we are indebted to the "Horological Journal":—

The altazimuth contains an azimuth compass, with aluminium disc, and a weighted disc for altitudes. Both these are graduated on their edges, and are read off through a lens, in a more simple manner than the ordinary prismatic compass. The instrument is ready for use immediately the catches that hold the discs are released. One face of the aluminium disc is plainly engraved, to serve as a good ordinary compass. One face of the weighted disc is divided, to serve as an ordinary clinometer, the box of the instrument being furnished with a fiducial edge.

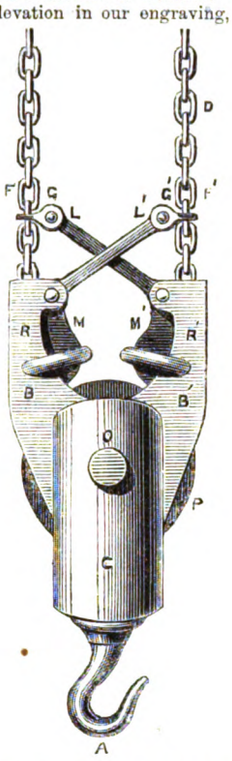


A stops or liberates the compass, on being made to slide backwards or forwards. B acts similarly on the clinometer, on being pushed in or drawn out. C is to be pressed in as a steady pin, before reading the compass. D is the lens of the compass; and E is that of the clinometer. To adjust these lenses, screw them a little, in or out, as required. To use the instrument, hold it vertically for altitudes, horizontally for azimuths, and so direct it that on carrying the eye from the hair line to the object about to be observed, they may be exactly in line. Then read off the division covered by the hair line.

The performance of an azimuth compass is well-known and appreciated. That of the weighted disc must clearly be far more delicate, inasmuch as the directive force of gravity is greater than that of terrestrial magnetism. Both discs are graduated to degrees. The principle of the weighted disc admits of index and other errors being discovered, checked, and eliminated. Two different readings may be obtained from the vertical circle, by observing with the clinometer's face first to the left and then to the right—the mean of these is clearly independent of index error. Again, by taking similar observations of the image of the object, as reflected in water, &c., two additional readings may be obtained, making four readings in all, or one on each quadrant of the disc The mean of these four must be almost wholly independent of instrumental error. A skilful observer, anxious to make the most of this little altazimuth will therefore find it very little inferior t ins ruments of far greater bulk, weight, and pretensions. An intelligent traveller furnished with the altazimuth may, by its use alone, map a country, take the height of mountains, and the dip of strata, and correct his position by very respectable astronomical observations. For, reckoning his accuracy of observation as being correct to one-tenth of a degree, his latitudes will be right to six miles, and his longitudes, by occulations, or (if he has a telescope) by Jupiter's satellites to within thirty miles.

SELF-ACTING SAFETY CATCH.

THE numerous accidents, many of a serious and lamentable nature, that have arisen from the breaking of chains, ropes, and other tackle employed in the hoisting of dead and live weights, have long since called forth various inventions for the purpose of obviating similar catastrophes. It was but the other day that seven men fell victims to the parting of a cable, snapping short at the drum, when engaged in lowering them down a tunnel shaft. In truth, it is not that there is any real want of means and appliances for preventing calamities of this character, but there is a very great want of some regulations, compelling them to be used upon every occasion, where their absence might be attended with disastrous consequences. From our contemporary, "Les Mondes," we extract a sketch of a simple and economical contrivance * for the purpose of preventing the fall of loads, consequent upon the parting of the chains or cables engaged in raising or lowering them. This little apparatus is readily fixed in position, demands no extraordinary attention, is self-acting, and performs its duty equally faithfully under all conditions of fracture. It is represented in elevation in our engraving, where P is



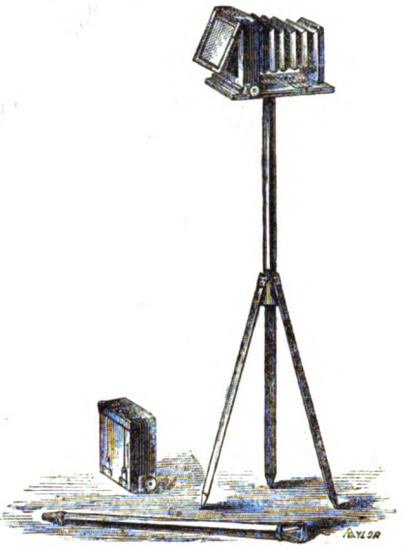
the hoisting pulley, C the spindle furnished with the two arms B and B¹ cast in a piece with it, and M M¹ a pair of movable jaws which clip the chain or cable, and are furnished with the levers L L¹. These levers are forked at one extremity, and slide in small guides G G¹. The jaws M M¹ are attached by springs R R¹ to the arms of the pulley B B¹. O is the axis, and A the shackle.

The manner in which the catch acts is as follows:—Suppose one of the chains F to break, the lower part falls and exercises no farther action upon the lever L, which is forced by the spring R¹ to assume a horizontal position, the jaw M¹ at the same time griping the portion of the chain passing along the other side of the pulley. As the failure of a chain generally results from the breaking of an imperfectly welded link, the remaining portion is amply strong enough to sustain the load until a new one is put into gear. In whatever manner the chain may break, the part remaining sound is sure to be held tight enough to secure it from running loose. From the fewness and simplicity of parts of which this little apparatus is composed, it promises to be strong and durable, and it possesses also the great advantage of acting without much shock. This arises from the comparatively trifling amount of space passed through by the chain after it has parted, and previously to its being clipped by the intercepting jaw. Many of the safety catches hitherto devised, although mechanically perfect, both in practice and theory, are complicated in their details, and not to be obtained at a price sufficiently low to ensure their universal employment, which is the chief desideratum.

* Designed by M. Caron, Rue St. Jacques, Paris.

POCKET PHOTOGRAPHIC CAMERA.

WE have just seen a very compact pocket camera and walking-stick tripod, the invention of Mr. C. D. Smith, and which we illustrate in the accompanying cut. This camera is con-



structed to hold plates 3¼in. × 3¼in., this size being convenient and most suitable for printing transparencies direct for use in the magic lantern, The outside measurement is only 4¾in. × 4⅝in. × 1¾in., and the weight 13oz., being much less than an ordinary-sized opera-glass. The stand is very compact and portable, is 36in. long when folded up, and when extended stands 4ft. 6in. high. This novelty is manufactured by Messrs. Negretti and Zambra, the opticians, of 153, Fleet-street, and will, doubtless, find favour with the photographic public.

ROYAL HORTICULTURAL SOCIETY.

ON Tuesday afternoon the first general meeting of the summer series of the Royal Horticultural Society was held. The council room was filled with a profusion of beautiful flowers, consisting of orchids, tulips, auriculas, pansies, and clematis. Among the novelties were a very pretty little buff-coloured begonia, and a bright yellow-flowered appelandra, from Messrs. Veitch and Sons. Mr. James Bateman, F.R.S., offered some observations on the cultivation of the loquat. Fine specimens of the rose apple in flower and fruit were exhibited, and a plate of St. George's azaric (azaricus gambosas), a vernal mushroom of excellent quality. Mr. W. Wilson Sanders, F.R.S., presided, and the following candidates were elected Fellows of the Society:—Lieutenant-Colonel Moore Brabazon, Mrs. John Bullar, Viscountess Dungarvan, Mrs. Gillespie, Mrs. Reuben Green, Mrs. Woronzow Greig, Mrs. T. J. Henderson, Mrs. Benjamin; Messrs. Lucas Judkins, Nathaniel Lindley, James L. Lobley, Octavius Vaughan Morgan, Arnold Moss, George Robinson, Edward Sheppard, and the Daventry Floral Society was admitted into union.

THE INSTITUTION OF CIVIL ENGINEERS

ON Wednesday last, the annual dinner of the Institution of Civil Engineers was held at Willis's Rooms, the company present numbering about 200. The chair was taken by Mr. Charles Hutton Gregory, the President of the Institute, who was supported by the Archbishop of York, the Duke of Argyll, the Earl of Caithness, Viscount Halifax, Lord Elcho, M.P., Lord Alfred Paget, the Lord Mayor, Admiral Sir John Hay, Bart., Sir Henry Holland, Bart., the Attorney-General, M.P., Sir Charles Trevelyan, K.C.B., Sir Charles Wheatstone, General Lefroy, the Presidents of the Royal, Astronomical, Geological, and Chemical Societies, and of the Institute of British Architects, the Deputy Master of the Trinity House, the Master of the Mint, Professors Sylvester, Tyndal, Donaldson, and Owen, Dr. Percy, Colonel Hutchinson, Colonel Rich, Mr. Bidder Mr. Hawkshaw, Mr. Fowler, and Mr. Vignoles Among the visitors and members of the Institution present, seated at eight cross-tables, which were presided over by Mr. Brunlees, Mr. Hemans, Mr. Cubitt, V.P., Mr. Hawkesley, V.P., Mr. Harrison, V.P., Mr. Bateman, Mr. Beardmore,

Digitized by Google

and Mr. Barlow, were Mr. Whitworth, Mr. Penn' Mr. Samuda, M.P., Mr. Brassey, Mr. Leeman M.P., Mr. Sherriff, M.P., Mr. Robertson, Mr. Hodgson, Mr. Mitchell, Mr. Giles, Mr. Shields. Mr. McConnell, Mr. Woods, Mr. Conybeare, Mr. Bramwell, Mr. Siemens, Mr. Bazalgette, Colonel Simmons, Mr. Coode. Sir Charles Lanyon, M.P., Mr. Cawkwell, Mr. Grierson, Mr. Forbes, Mr, Beyer, Mr. Ravenhill, Mr. Ashcroft, Mr. H. A. Hunt, Mr. Murray, Mr. Aird, Colonel Kennedy, Mr. Strapp, Mr. Chance, Mr. Chilton, Mr. Baker, Mr. J. Shaw, Mr. Myles Fenton, Mr. Rennie, Mr. Colburn, Mr. Cochrane, Mr. Field, Mr. C. Waring, M.P., Mr. Kelk, M.P., Mr. C. Lucas, Mr. Blair, Colonel Clarke, Mr. Longridge, Mr. Bruce, Captain Tyler, and Major Palliser, with Mr. Charles Manby, F.R.S., honorary secretary, and Mr. James Forrest, the secretary. The usual loyal toasts were enthusiastically received. Those of the Army, Navy, Militia, and Volunteers, were acknowledged by General Lefroy, R.A., Admiral Sir John Hay, Bart., M.P., and Lord Elcho, M.P. The honours paid to the Houses of Lords and Commons, and to the visitors, were responded to by the Earl of Caithness, the Attorney-General, and the Archbishop of York. General Lefroy, and Sir John Hay, spoke very hopefully of the army and navy, and Lord Elcho aptly associated railways and engineering works in general with the national defences. The Archbishop of York happily touched upon Mr. Whitworth's munificent gift, in the cause of scientific instruction, which he designated the best shot he had ever fired in his life. The Duke of Argyll, who incorporated in his speech more than one local reminiscence, the purport of which was to show that Scotland is the cradle of our best engineers, proposed the toast of the evening, coupling it with the name of Mr. Gregory. Mr. Bidder gave "The Learned Societies," and the President of the Royal Institute of British Architects, Mr. Tite, who returned thanks; and the toast of "The Corporation of the City of London" was proposed by Mr. Hawkshaw, and acknowledged by the Lord Mayor. The entertainment passed off admirably, and was certainly one of the best the Institute had ever had.

Turning to the business proceedings of the Institute we note that at the ordinary general meeting held on the previous day, Mr. Gregory in the chair, twenty-two candidates were balloted for and duly elected, including five members, viz.: Mr. William Bage, Mr. Francis Brady, Mr. Maximilian Hjortsberg, Mr. George Vivian, and Mr. John Wood; and seventeen associates, viz.: Mr. Charles D. Alexander, B.A., Le Chevalier Barroso, Mr. Edwin Bidder, Mr. Peter Brotherhood, Mr. Joao N. Ferreira, Mr. Thomas Gibson, Mr. James Hartley, M.P., Mr. Edward J. Jones, Mr. H. A. O. Mackenzie, Mr. John Milroy, Lieutenant Colin C. S. Moncrieff, R.E., Lieutenant Patrick Montgomerie, Mr. Walter Neilson, Mr. Samuel B. Newton, Mr. Richard Proctor-Sims, Mr. Horace J. Rydon, and Mr. William J. Trehearne. It was also announced that the Council, acting under the provisions of Section IV. of the Bye Laws, had, since the last announcement, admitted as Students of the Institution, Messrs. John S. Carey, Humphrey Henchman, and John A. Owen.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

A VERY crowded meeting of the members of this institution took place at their rooms in Aldermanbury, City, on Saturday last, Mr. Joseph Newton, President, in the chair. Much interest had previously been excited by the announcement that E. J. Reed, Esq. (Chief Constructor of the Navy), would read a paper, on the testing of iron and steel. At half-past eight, Mr. Reed entered the lecture hall, accompanied by Mr. Stock, M.P., Mr. Edward Humphrys, and other eminent scientific gentlemen. The chairman opened the proceedings by stating that there was no need for a lengthy introduction of the lecturer on this occasion, as Mr. Reed was well known to all present. For the last ten years Mr. Reed had been a devoted supporter of that Association, and had rendered it as much service as any member of its managing committee. It was equally unnecessary to claim attention to any remarks which might emanate from the Chief Constructor of the Navy, for they were always worth listening to, and were sure to be instructive.

Mr. Reed then, in a very elaborate statement, illustrated by carefully-prepared diagrams, explained the various modes employed by the Admiralty for testing the quality of iron and steel supplied by contractors for use in the British navy. His practical description of the very severe ordeal through which all such materials were made to pass before finding acceptance at the hands of the authorities, were heard with, apparently, the greatest interest, and it seemed almost impossible that, under the circumstances indicated, any iron or steel of an inferior character could possibly find its way into the construction of ironclad ships. On the conclusion of the paper, the hon. member for Carlow (Mr. Stock) expressed the pleasure he felt in having been privileged to attend the sitting of that evening. He considered that an institution of the nature of the Association of Foremen Engineers was well calculated for the promotion of scientific and technical knowledge, and must at once elevate its members and advance the engineering profession in the United Kingdom. Mr. Reed's paper was worthy of himself, and could not fail to be of value to his audience. Mr. Edmonds recounted his own extensive experiences in the testing of metals at the Royal Arsenal, Woolwich, and agreed in the main with the views put forward by the reader of the paper. Messrs. Keyte, Waring, Campbell, Stabler, Roberts, and others, took part in the discussion which ensued, and which was of a critical and spirited nature. When Mr. Reed had replied to the several queries propounded, and elucidated some points upon which further information was requested, a vote of thanks to that gentleman, proposed by Mr. Gibbon and seconded by Mr. Waring, was put to the meeting by the chairman. It is needless to say that it was unanimously agreed to, and gracefully acknowledged. In closing the sitting, Mr. Newton expressed a hope that other honorary members of the Institution would follow the example now set by Mr. Reed, and thus render its monthly meetings yet more attractive and useful than heretofore.

MANCHESTER BOILER ASSOCIATION.

THE last ordinary monthly meeting of the executive committee of this Association was held at the offices, 41, Corporation-street, Manchester, on Tuesday, April 28, Hugh Mason, Esq., of Ashton-under-Lyne, Vice-President, in the chair, when Mr. L. E. Fletcher, chief engineer, presented his report, of which the following is an abstract:—During the past month 227 visits of inspection have been made, and 478 boilers examined, 278 externally, 6 internally, 6 in the flues, and 188 entirely, while in addition 3 have been tested by hydraulic pressure. In these boilers 95 defects have been discovered, 10 of them being dangerous.

The following is a statement of defects, omissions, &c., met with in the boilers examined from March 28, 1868, to April 24, 1868, inclusive:—Furnaces out of shape, 2 (1 dangerous); fracture, 21 (2 dangerous); blistered plates, 12 (1 dangerous); internal corrosion, 12 (2 dangerous); external corrosion, 14 (2 dangerous); internal grooving, 9 (1 dangerous;) external grooving, 5; total number of defects in boiler, 75 (9 dangerous). Feed apparatus out of order, 1; water gauges out of order, 1; blow-out apparatus out of order, 3; safety valves out of order, 1; pressure gauges out of order, 6; total number of defective fittings, 12. Boilers without feed back pressure valves, 6; total number of omissions, 6. Cases of deficiency of water, 2 (1 dangerous). Gross total, 95 (10 dangerous).

In three internally-fired mill boilers, which were unhoused and set below ground, the plates on the top were found, on being uncovered, to be dangerously corroded, in one of them so much so that three or four plates would have to be removed, while in another such extensive repairs were necessary that, having regard to the age of the boiler, it was thought better to condemn it altogether. This shows the disadvantage of placing boilers in inaccessible positions, while it is recommended that the covering of those that are unhoused should be lifted at least once in two years for examination.

Two explosions have occurred during the past month, by which two persons have been killed and two others injured. Neither of the boilers in question was under the inspection of this Association. The following is the statement of explosions from March 28, 1868, to April 24, 1868, inclusive:—April 4, plain cylindrical boiler, egg-ended, externally fired—1 killed, 2 injured. April 7, two-flued Lancashire boiler, internally fired—1 killed. Total, 4—2 killed, 2 injured. No. 9 explosion, which occurred at a colliery on the morning of Saturday, April 4, and resulted in the death of one man and injury to two others, is simply an illustration of the danger of externally-fired boilers. The boiler was one of a series of four working side by side, and connected together, all of them being of the plain cylindrical egg-ended, externally-fired class so commonly used in collieries, while the exploded one measured 28ft. in length by 6ft. in diameter, and ⅞in. in the thickness of the plates, the load on the safety valve being 30lb. on the square inch.

It appears that the boiler was about twenty-nine years old, and had been frequently repaired at the plates over the fire, while one of these repairs had just been completed, and the boiler only set to work a few hours before it exploded. The repair was considered by the engineer to the collieries to have made the boiler perfectly safe, and he could not at all account for the explosion; notwithstanding which, however, just as some colliers had been lowered down the shaft, and the stoker was in the act of putting some coals on the fire, a few hours after it was set to work, the boiler burst, blowing the poor man out of the firing space and killing him on the spot, in addition to knocking down the chimney and dislodging one of the adjoining boilers, while its own shell was rent into three fragments, one of which was thrown to a distance of 60yds., another 42yds., and the safety valve 30yds, a portion of a brick being shot through the roof of the cottage—though at a distance of 60yds.—in which the stoker who was killed by the explosion had lived.

The boiler failed, in the first instance, just at the part where it had been repaired by a patch immediately over the fire, the old work tearing away from the new. This is frequently found to be the case, so that these boilers are often weakened by the very means adopted to strengthen them, and their explosion hastened rather than arrested by repairs. Explosions of this nature will recur as long as the use of these treacherous plain cylindrical externally-fired boilers is persisted in.

IRRIGATION IN INDIA. *

By Mr. T. Login, F.R.S.E.

THIS paper was on the benefits of irrigation in India, and on the proper construction of irrigating canals. The author stated that he had been engaged, during the greater part of a quarter of a century, on some of the most important irrigation works in Northern India, and an account of the prominent features of the system formed the subject of this communication. With regard to the revenue derived from the older canals and their actual cost, diagrams were exhibited, showing that, at least in Northern India, immediate direct returns must not be looked for, although such canals were certain to be financially successful eventually. If, however, in addition to the water rent, the increase of cultivation and the enhanced value of land were included, the canals even in this part of the empire must be considered highly remunerative. But the strong argument in favour of canals was, that they were calculated to prevent those awful visitations which from time to time swept off hundreds of thousands by starvation; and if canals could be constructed at an outlay of somewhat less than one pound sterling per head of the population, and return a fair per centage for the outlay, these were additional reasons for proceeding with them without delay.

The abrading and transporting power of water in motion was briefly adverted to, and the author expressed the opinion that the power of water to hold matter in suspension was directly as the velocity, and inversely as the depth; and that with given velocities and defined depths, only a certain quantity of matter could be held in suspension, whatever might be the character of the bed and banks of the river or canal. If the velocity were increased, and the depth remained constant, scour would take place; whereas if the velocity were decreased, and the depth was the same, there would be deposit.

With reference to the best slopes for canals, and how the slopes were to be regulated, it was essential, in the first place, to ascertain what was the slope of the river, when not in flood, from which a supply was to be drawn, under circumstances similar to those of the canal to be constructed, that was as to depth and soil; and then to make a small allowance for the tortuous course of the natural river. The slope—that was the velocity, or, in other words, the abrading and transporting power to be given—should be such, that the deposits would be balanced by the abrasion. Experience on the Ganges Canal had shown that this required a mean velocity of about 3¾ft. a second, with a surface slope a little less than 14in. in the mile. One of the greatest

* Read before the Institution of Civil Engineers.

Digitized by Google

problems for the canal engineer was the best method of dealing with the excessive slope of the country through which an artificial river had to flow. In Nature this was provided for, first, by waterfalls; secondly, by barriers of rock, stretching like weirs across the channel of the river; thirdly, by rapids, formed of boulders that had been carried down the river, thus creating temporary weirs; and lastly, where only clay or sand existed, the course of the river was found to be tortuous, by which the length was increased, and the slope practically reduced; and, to a minor extent, the flow was also retarded by the sudden bends in the river, which tended to check the velocity and to increase the depth. The last plan had been almost invariably adopted in former times, and it was still to be seen in Egypt; one of the largest and best paying canals in Upper India—the Western Jumna Canal—was also constructed on this principle.

The experience gained on the Eastern Jumna Canal, where masonry falls were built after it was opened, led to the adoption of the ogee form of fall for the Ganges Canal. While these works were in progress, the flooring of all the falls on the first division was lowered so as to form a cistern to receive the descending water; and the water being held up by a framework of timber, 5ft. in height, above the crown of the ogee, no injury has as yet been done to the brickwork where the water impinged. This was probably owing to the water which passed through the open spaces of the timber framework forming a cushion for the descending water. Perpendicular falls were also employed on the Baree Doab Canal, and in Madras; but in the former the water was received into a cistern, while in the latter it impinged on a flooring of ashlar work. The various plans adopted and proposed for overcoming excessive slopes having been succinctly noticed, it was stated that, under such circumstances, recourse must be had to barriers, or, as they were technically termed, weirs. From a table showing, approximately, the sections and slopes best adapted for irrigation canals and water courses in Northern India, it appeared that probably the best slope for a canal discharging 5,000 cubic feet per second was about 13¾in. per mile.

A description was then given of a new system of "zig-zag" falls which had been recommended; by the author for the Rechna irrigation works and a comparison was instituted between the cost of the falls and bridges on the Ganges Canal as executed, and the estimated cost if the proposed "zig-zag" falls had been adopted, from which it was contended that there would have been a considerable saving of expense by the latter plan. As to the question whether the falls would be likely to stand the action of the water, it was proposed that the length of the lip should be so extended, that only 10 cubic feet a second should pass over each foot, which with a full supply would require a height of about 2ft.; whereas, on the Ganges Canal, with two and a-half times the volume descending an equal height on brickwork, no injury had yet occurred.

In conclusion it was remarked that six years ago, the author stood almost alone in maintaining the opinion, that the Ganges Canal needed only some protective works, and did not require the radical alterations then proposed. He believed that the works might be placed out of all danger, by the judicious use of wood and iron, at a less cost than if stone were employed, without depriving the country of the benefits of irrigation beyond a very short time.

DEEPENING OF THE MICHIGAN AND ILLINOIS CANAL.*

By S. W. Robinson, C.E.

THE valley of the Des Plaines River, in the State of Illinois, is supposed to have been at some period during the geological ages, the course of a river which formed an outlet to the Great Lakes, and a tributary to the Mississippi. The bed of this valley, at present, scarcely rises 25ft. above the level of Lake Michigan, the summit being only ten or fifteen miles from the lake. The Michigan and Illinois Canal, which extends down this valley, is ninety-six miles in length, and joins Lake Michigan, at Chicago, with the Illinois River at La Salle. This canal was commenced about thirty years ago. It has now been in use for several years, the boats being carried over the summit by the use of locks, situated at Chicago and near Lockport, which retain the water upon a level 10ft. higher than the Chicago River and Lake Michigan.

Since the city of Chicago has suffered in such a marked degree from the notable stench of the Chicago River, it has been determined to deepen this canal across the summit, so as to induce a current of water down the valley into the Illinois River. This will form an artificial river, by which water will be carried from the lakes towards the Gulf o Mexico. Although the amount of water carried to the sea by this course will be small, yet the fact will exist of two outlets to divide the waters of the great lakes, and depreciate the honours of the St. Lawrence. The amount of deepening required to effect this is about 10ft. between the locks above named, for a distance of twenty-seven miles. The working depth of the canal is to be 6ft., reckoned from the low-water mark of Lake Michigan; the breadth of the canal at the bottom is to be 50ft., and 6ft. from the bottom 60ft. This work of deepening was commenced two years ago; and will probably be finished by the middle of April, 1869. That navigation shall not be interfered with, the work is done between the middle of the months of November and April, each winter. The deepening requires the removal from the bottom of the canal of about two and a-half million yards of earth, 240,000yds. of solid rock. The former is contracted variously at from half a dollar to a dollar per yard, and the latter at from 2¼ to 2½ dollars per yard.

The city is permitted by the State to prosecute this work to the extent of two and a-half millions of dollars, with the understanding that it shall be reimbursed by revenues from the canal, if not sooner paid directly by the State, which, the writer has been informed, will be done, if the State widens the canal to 80ft. or 100ft., to accommodate the Mississippi flat-boats. The excavation is earth for a distance of twenty miles from Chicago, where the excavation of magnesium lime-rock commences, which extends about seven miles further, reaching nearly to Lockport. This part of the canal runs through the limestone beds from which the excellent building stone for the city of Chicago is quarried. To loosen the rock in the canal, blast-holes are used, which are 4in. to 6in. in diameter and 6ft. to 10ft. deep. These have heretofore been bored by raising the drills by horse or steam power, then letting them drop, gravity doing the work of striking the blow.

The drills principally used for this purpose are about 20ft. in length and 2½in. or 3in. in diameter, and of iron, except at the cutting end, which is enlarged with steel to nearly the size of the hole for 1ft. or 2ft., and armed with a Z-bit. Experiments are now being made with direct-action steam drilling machines at the works of Messrs. Singer and Talcott. Much difficulty has been experienced in effecting the speedy removal of the chips, which are formed so much faster than by other appliances heretofore used for drilling. This difficulty, however, is likely to be overcome; and the time is probably near at hand when direct-action steam-drills will be used on all our great works in rock excavation throughout the country. The rock is raised from the bottom of the canal to the banks by means of cranes or derricks, worked by horse-power. The cranes have the advantage of being portable, being mounted upon movable platforms. The derricks, however, perform the operation of hoisting more satisfactorily, and require less work than the cranes, as there constructed.

The easiest working derricks used there are those in which the boom would swing entirely around the mast in disposing of each load. They were so constructed that the horse or horses travelled around the mast, and in the same direction as the boom. The mast rests upon the centre of the sweep to which the horse is attached, and the friction between the mast and sweep, induced by the movement of the latter, causes the boom to move and carry the load around simultaneously with being raised, from the pit to the bank, ready to be dumped. One of the smoothest working derricks I saw had a friction clutch for communicating power to the cable, the latter being of steel wire instead of a chain. One horse worked this with apparently as much ease as two could the cranes, having a chain cable, and where the chains required two to four men each, beside the driver, to manage them, the derricks required but one. These derricks were invented by A. T. Merriman and Brother, of Chicago.

* "Journal of the Franklin Institute."

Legal Intelligence.

COURT OE QUEEN'S BENCH.

May 4.

(Sittings in Banco before the Lord Chief Justice, Mr. Justice Blackburn, and Mr. Justice Hannen.)

WEBB V. RENNIE.

This was a case which has already been twice tried before the Lord Chief Justice and a special jury, and in both trials the verdict was for the plaintiff; and it now, for the second time, came before the Court on a question as to the sufficiency of the evidence to sustain such a verdict. The details of the case were given and its merits were fully discussed by us in our issue for November 8, 1867, page 307. It may, however, be necessary to state here that the action was against the eminent shipbuilders, Messrs. Rennie, by a workman in their employment, to recover compensation for an injury sustained while at work in their yard, by reason of the falling of a pole which supported a frame on which he was working. The pole fell by reason of its rottenness at the end fixed in the earth, and the point was whether the defendants, the employers, were liable for its not having been examined before it was used. It was of white pine, and had been two years in the earth, and evidence showed that such poles were likely, when left in the ground, to become rotten and liable to break. The question, therefore, came to this, who was to blame for not taking it out and looking at the end of it to see if it were sound before it was used as a support of the frame. As to this it appeared, on the one hand, that the defendants were daily in the yard, and, on the other hand, that they had a foreman or manager who had been upwards of twenty years in their service, and who, of course, knew all about the poles, and whose duty it would be to look after them and see if they were sound. But on this occasion the pole was not examined, and it broke off at the bottom, being quite rotten. The argument on the part of the plaintiff was that the employers were liable for bad materials; the argument on behalf of the defendants was that there was no personal or actual negligence on their part.

Mr. D. Seymour and Mr. Daly were for the plaintiff; Mr. M. Chambers and Mr. Woolett were for the defendants.

After hearing the plaintiff's counsel, the Court, without calling on the counsel for the defendants, gave judgment in their favour. They were bound, they said, to determine the case in accordance with the numerous decisions which established the doctrine that a master was not liable for injuries to his workmen arising from the negligence of his fellow servants. The evidence in this case established no exception from the general doctrine. The defendants had a competent and experienced foreman whose duty was to examine the poles, and the accident had arisen from his negligence or neglect. There was no evidence on the part of the defendants in delegating such a duty to him, for he might well be deemed reasonably competent and proper for its discharge. It was his negligence, not theirs, to which the accident was to be ascribed, and therefore the action was not maintainable against them. The Court did not question the opinion of the jury that there was negligence, but the question was whose negligence it was; and the Court were of opinion, upon the evidence, that it was the negligence of the foreman, not of the master.—Judgment for the defendants.

Correspondence.

PRESERVING GUTTA-PERCHA.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I should esteem it a favour if you, or any of your readers, can inform me whether there is any varnish or composition which can be applied to a model made of gutta-percha (without heat), which will prevent the summer atmosphere from softening the same; in fact, anything that would render gutta-percha, after being formed into a delicate model, quite proof against an atmosphere of about 80deg. I may add that the article referred to will be required to be coated with gold bronze, so perhaps you will kindly say whether this can be done previously or subsequently to the operation. By affording the above information you will greatly oblige.—I am, Sir, yours, &c., AN EXPLORER.

May 4.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Meetings for the Week.

MON.—Royal United Service Institution.—Colonel A. Cunningham Robertson, 8th or King's Regiment, on "The Appointment and Promotion of Regimental Officers," at 8.30 p.m.

TUES.—The Institution of Civil Engineers.—Continued discussion on "Irrigation in India and in Spain," at 8 p.m.

Royal Institution.—Dr. M. Foster on "The Development of Animals," at 3 p.m.

THURS. — Royal Institution. — Professor Bain on "Popular Errors," at 3 p.m.

FRI.—Royal Institution.—Mr. E. Deutsch on "The Talmud," at 8 p.m.

SAT.—Royal Institution.—Professor Bain on "Popular Errors," at 3 p.m.

Naval, Military, and Gunnery Items.

THE annual dinner of the officers of the Royal Engineers will take place on Thursday, the 21st inst., at Willis's Rooms. The Duke of Cambridge will preside.

THE First Lord of the Admiralty will hold a levee on Thursday, the 14th inst., at which he will receive those officers whose names were noted for the levee of the 7th ult.

THE admiral good service pension of £300 a-year, vacant by the death of Admiral Sir Hy. D. Chads, K.C.B., on the 7th ult., has been granted to Admiral Sir Robt. L. Baynes, K.C.B., from that date.

INSPECTOR GENERAL DR. BEATSON, the late head of Her Majesty's British army in India, has arrived in England, after a long tour in the former country. He proceeds to Netley as the principal medical officer of that establishment. We, "Lancet," congratulate Dr. Beatson on his arrival home. Intelligence as to the distinguished way in which he discharged his duties in India has long preceded his arrival.

ON Tuesday, at the Admiralty Court, an application was made in the case of the "Great Eastern" steamship, which is under arrest at this court in reference to a large claim, to amend the petition as to the French company which had chartered the vessel on account of the Paris Exhibition. Mr. V. Lushington and Mr. Butt appeared in the case. The court granted the application, and the case will now proceed to hearing on an important question of liability.

THE Board of Trade have awarded to Captain Francois Breynairt, master of the French steam tug, "L'Industrie," a telescope value £5 15s. 6d., in acknowledgment of his humane services in rescuing from the rigging of their vessel the crew of the schooner, "J. F. Buller," which stranded off Dunkirk on March 7, last. The Board of Trade have also awarded a similar telescope to Captain Nicolai Lindal Walloe, master of the ship "Washington," of Tonsberg, in acknowledgment of his humanity in receiving on board his vessel the master and crew of the brig "Ellen," of Whitby, which encountered bad weather on her passage from Gefle to West Hartlepool, and was necessarily abandoned.

A SAD accident occurred a few days back at Vincennes during the target exercise of the soldiers forming part of the camp of St Maur. A spectator placed at the line of distance fixed by the authorities as quite beyond the range of the fire was struck by Chassepot bullet, which passed through his hand and then entered his groin. The new firearms, it thus appears, have such a force of projection as to exceed the calculations of the military officers best acquainted with the subject. The wounded man was a resident of St. Maur, and had been recently married. After surgical assistance had been rendered he was removed to his home with every precaution.

THE total number of soldiers sent on furlough by the Commander-in-Chief of the North German Federal Army amounts to 12,000.

A LARGE screw steamer, named the "Travancore," has just been built for the P. and O. Steam Navigation Company by Mr. Kay, of Kinghorn. The vessel is 300ft. long, of 2,300 tons burden, and with engine of 400-horse power. The crew numbers 110, officers and men. The principal saloon, which is a very handsome apartment, is 70ft. long by 15ft. wide. The ice-room has a capacity for 20 tons, and a constant supply of iced water can be laid on by a connecting tap. Steam pipes are laid on where either power or heat is required. There are two marble baths for ladies, and seven for gentlemen.

THE "Journal des Connaissances Medicales" describes a couple of slaughter engines, which are suggested as the right things to use in future warfare. One is the Mitrailleuse, and it is described as something resembling a huge coffee mill in shape, into the funnel of which the cartridges are thrown by shovelfuls. A soldier turns the handle, and the movement keeps up a supply of bullets to each of eight barrels, and causes a hammer to rise and fall rapidly on the percussion caps, the whole resulting in a discharge of from fifty to fifty-five shots per minute, to a point-blank distance of 1,700yds. It is to be served out to the battalions of chasseurs, each section of which is to have one. We presume this to be the Gatling gun. The other contrivance is the Foudroyant. It is a species of musket, which discharges two bullets per second from a reservoir for cartridges. As each shot passes out of the barrel it acts upon a lever, which draws a fresh cartridge from the reservoir, and places it on the breech.

A PARLIAMENTARY paper has just been published, which contains Admiral Warden's reports of the trials of the Channel Fleet in 1867, with the remarks of Vice-Admiral Robinson, the "Controller" of the Navy, thereon. The observations of the "Controller" consist of a critical analysis of the performances of the several ships in the squadron as recorded by Rear-Admiral Warden; but in the detailed reports there are very great discrepancies, which further trials alone can clear away. After the most careful consideration, Admiral Robinson can see no encouragement whatever in these reports to return to the construction of unhandy, long, and comparatively slightly-armoured ships; on the contrary, so far as they go, they thoroughly confirm the propriety of the changes that have been made in the forms of ships recently constructed—less length, and greater fighting power combined with handiness, having been secured to them. The engines of the new type alone give cause for dissatisfaction, and they only in some instances, the peculiarities of which are now undergoing the most careful inquiry.

THE "Memorial de la Loire" gives some particulars respecting a French gunmaker, named Bourgaud, who was for some time in the service of King Theodore, but whose fate seems at present uncertain. He formerly carried on business at Saint Etienne, and ten years since conceived the idea that he might open a profitable trade in Abyssinia. Proceeding thither he was warmly received by the King, and treated with distinction, and is even said to have been a Prince. But when M. Bourgaud desired to leave, he discovered that to get into Abyssinia was easier than to get out of it. The Negus found him too useful, from his special knowledge of arms, to part with, and he was retained in a sort of honourable imprisonment. Three years elapsed, and his wife, despairing of his return, decided on going with their children to Magdala with a view of bringing him back to France. They also were well received, but were likewise prevented from returning to Europe. What has become of M. Bourgaud and his family is not yet known.

WE see by the "United Service Gazette" that an act of justice has at last been done by the Admiralty in the promotion of Commander Bedford Pim to the rank of captain. Before attaining the rank of lieutenant Captain Pim served in all quarters of the globe, but this, his first step, came by seniority, and, moreover, he passed the best examination of his day at college. He volunteered, and was employed in three Arctic expeditions, and was the connecting link of the North-west Passage, saving from starvation and death the officers of Her Majesty's ship "Investigator," when hopelessly beset in the ice. He afterwards served with distinction in the Russian and last Chinese wars, and was wounded on three occasions, twice severely, once receiving six bullet wounds. Captain Pim is favourably known as an author and writer of considerable ability. He has devoted much time, energy, and money during the last six years to his great project of opening a transit through Nicaragua, and which is now in a fair way of being carried on.

Miscellanea.

MR. JOHN MELLOR, an antiquary of Derby, states that he has discovered the remains of King Alfred at Hyde Abbey, Winchester.

THE number of visitors to the Patent-office Museum, South Kensington, for the week ending May 2, was 2,915; total number since the opening of the museum free daily (May 12, 1858), 1,292,893.

THE quantity of proof spirits distilled in the United Kingdom and Ireland, during the year ending the 31st December last, was 23,323,613 gallons. The duty paid amounted to £11,382,594 5s. 7d.

FROM a statistical return just published it appears that the damage done in Normandy in 1866 by the larvæ of the cockchafer amounted to no less a sum than twenty-five millions of francs.

A NEW public park thirty acres in extent, was on Friday last formally opened at Southport by Mr. Peter Wood, the mayor. The land for the park was presented about four years ago by the Rev. Charles Hesketh, the rector of Southport.

"WHAT is the use of you gentlemen going to college?" said a farmer in conversation with one of the assistant commissioners engaged in the recent Schools Inquiry. "My son Walter can write a better hand than you." And the commissioner confesses the fact to be so.

A FACT showing the influence of artificial light in the production of green colouring matter is recorded by M. Ermins, in a recent number of the "Revue Horticole." Some lilacs were placed for forcing in a heated cellar, partially lighted with gas. Those leaves that were exposed to the light became green, as if they had been in the open air, while the remainder were etiolated.

AN offer of £3,000 has been made as an endowment for a chair of Applied Mental Science in the University of Edinburgh, on condition that £1,500 or £2,000 more be obtained from other sources.

AT the meeting of the Royal Geographical Society, on Monday evening next, Sir R. I. Murchison, Bart., president, will occupy the chair, and the following papers will be read:—1, "On the Peninsula of Sinai," by the Rev. F. W. Holland; 2, "North-east Coast of Labrador," by Commissioner W. Chimmo, R.N.

ON the 1st inst., the Franco-Italian Commissioners completed their examination of the Mont Cenis Railway, and authorized its being opened for goods traffic for a fortnight prior to the opening for passengers. On the return journey of the Commissioners from Susa to San Michel the time occupied was 5h. 80min., including 1h. 15min. stoppages. The average running speed was about twelve miles an hour.

THE visitors to the South Kensington Museum during the week ending May 2, 1868, were as follows:—On Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 9,215; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 2,252. National Portrait Exhibition, by payment, 2,930; Total—14,397. Average of corresponding week in former years, 12,696; total from the opening of the museum, 7,359,342.

AT the recent important meeting of the Royal Geographical Society, Mr. Camden Hotten exhibited a volume of pen and ink sketches of remarkable scenery in Abyssinia, with portraits of the natives, taken by a German, T. Essler, one of the prisoners just liberated from the hands of Theodore. These drawings are now in course of publication by Mr. Hotten, and the work will, by royal command, be dedicated to Her Majesty the Queen.

IT was announced at the meeting of the Institution of Mechanical Engineers, held on Thursday last, at Birmingham, that in consequence of a memorial, dated 20th March last, it has been decided to appoint three honorary commissioners to act with the Lord Chancellor and the Master of the Rolls in regulating the Patent Office. The first name is to be suggested by the Institution of Mechanical Engineers, the second by the Chemical Society, and the third by the Royal Society. The Institution of Mechanical Engineers have nominated Messrs. Amos and R. May.

ON Tuesday week, about five o'clock in the evening, intelligence reached Cardiff that a dreadful accident had occurred at No. 3 shaft on the Caerphilly branch of the Rhymney Railway. During the dinner hour a man had been working in the shaft, and asked to be pulled to the top of the shaft. Shortly afterwards six other men joined him to proceed to their work in the shaft. When the engine was set in motion it was found that the gearing had got out of order, and before it could be remedied the whole of the men were thrown from the top of the shaft to the bottom, a depth of 117 yards.

OUR facetious contemporary, "Punch," has the following "Science Gossip":—The proper thing to use with gun-cotton is shot silk.—The cuckoo has been heard on Bethnal-green, and the nightingale has commenced singing in Short's-gardens. The swallows have returned to the Mansion House.—A patent has been taken out for manufacturing pens with cocoa-nibs.—Ladies will be pleased to hear that a process has been discovered by which they can electro-plait their hair.—Many persons have burnt their fingers by dabbling in petroleum.—A scientific ghost story will shortly appear in fortnightly numbers, founded on spectrum analysis. These extracts may serve to allay any alarm on the part of Mr. Hardwicke.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—2953, 2987, 2997, 3000
BUILDINGS AND BUILDING MATERIALS—2938
CHEMISTRY AND PHOTOGRAPHY—2952
CULTIVATION OF THE SOIL, including agricultural implements and machines—2945
ELECTRICAL APPARATUS—2942, 2960
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2932, 2946, 2947, 2951, 2974, 2985, 2996, 3005
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—2931, 2940, 2976, 3006
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—2933, 2936, 2939, 2950, 2956

Digitized by Google

GENERAL MACHINERY—2934, 2935, 2962, 2964, 2969, 2975, 2978, 2981, 2982, 2990, 2995, 2998, 3004
LIGHTING, HEATING, AND VENTILATING—2968, 2989
METALS, including apparatus for their manufacture—None.
MISCELLANEOUS—2943, 2944, 2948, 2957, 2959, 2963, 2966, 2970, 2971, 2972, 2977, 2979, 2983, 2984, 2988, 2991, 2994, 3002, 3007, 3008, 3009
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2954, 2955, 2965, 2967, 2986, 2992, 2993
SHIPS AND BOATS, including their fittings—2937
STEAM ENGINES—2980
WARFARE—2941, 2949, 2961, 2999, 3003

2931 H. J. BALE. *Improvements in apparatus to be used in cooking by means of gas.* Dated October 18, 1867.

In order that an ordinary gas burner carried by a bracket projecting from the wall of a room or chamber may from time to time be used in cooking, the patentee employs apparatus consisting of a bucket so constructed as to be readily applied and secured to the wall of the room or chamber required for use, and afterwards removed from it. This bracket carries a ring or platform to support a pot or kettle, and is jointed so that the platform may be brought over the burner, or swung to one side of it, by moving about the joint in the bracket. He fixes to the wall of the room or chamber where the bracket is to be applied, and in the vicinity of the gas burner, two nails or studs having heads; the base plate of the bracket has holes through it of a size to allow these heads to pass, and the holes are slotted on the upper side, so that when the plate of the bracket has been applied over the nails or studs, it drops down or slides along so as to bring the stems of the studs or nails into the slots, and thus the plate becomes secured to the wall.—Patent completed.

2932 T. WHITEHEAD. *Improvements in roving and spinning fibrous substances.* Dated October 18, 1867.

In the roving frame the inventor takes the roving from a thicker roving than heretofore, and passes it through one or two troughs of hot or cold water, in which, in some cases, suitable chemical agents may be dissolved, then through holding rollers, and then drawing rollers to draw the sliver smaller. Then it is passed round one or more grooved or plain steam rollers, so as to dry the fibre before going on to the bobbin, but so arranged that one or more slivers may be wound on the same bobbin. Another portion of the invention consists in a novel application of a fixed collar to extend the full length of the traverse part of the spindle, so that the bobbin runs upon the fixed collar or tube, instead of upon the revolving spindle, thereby enabling the spindle to make more revolutions.—Patent abandoned.

2933 S. S. MAURICE. *An improved fastening.* (A communication.) Dated October 18, 1867.

Here a movable plate which has, by preference, teeth on one of its edges, and which is hereinafter called the working plate, works on two projections, pivots, or axes, one of which is cranked; these pass through the sides of another plate, which the patentee calls a frame plate, and to which is attached a bent plate forming a spring, through one end of which the crank projection or pivot passes. The working plate is actuated by exerting pressure on it by means of a knob, or similar appliance. Holes are provided in the working plate and frame plate to sew or stitch the necktie or other article thereto.—Patent completed.

2934 J. KING. *Improvements in machinery or apparatus applicable to cages or hoists used in mining or lifting machines.* Dated October 18, 1867.

The patentee claims, first, the construction, arrangement, and combination of two pairs of eccentric pulleys (or clutches), such pulleys (or clutches) being fixed on to the sides of the guide rods of the cage or lift by double-ended spring links or levers, such links or levers, being allowed to act on the pulleys (or clutches) by the overwinding or breaking of the hoisting chain or rope, cause the pulleys (or clutches) to hold the cage or hoist or lift suspended in the shaft or well hole in which it is employed, substantially as described. Second, the arrangement and combination of machinery or apparatus, substantially as described.—Patent completed.

2935 J. J. HOLDEN. *Improvements in apparatus for cleaning and polishing boots, shoes, and other foot coverings, which apparatus may also be adapted for cleaning certain other articles.* Dated October 18, 1867.

Here a framework supports a fly-wheel or driving-wheel, which is actuated by a handle or treadle, and transmits rotary motion by strap and pulley, or otherwise, to two or more shafts placed at the upper part, lower part, and sides (or at two or more of such parts) of the framework. When used for boots, shoes, and the like, these shafts carry brushes made concave at their peripheries, and set on concave stocks, or concave parts of the shafts, and they have projecting ends to accommodate their shape to the boot, shoe, or foot covering. Between the brushes the shafts are made concave. Each shaft or spindle should carry three brushes—one for cleaning off mud, another for applying blacking, polish, or varnish, and a third for rubbing or polishing. The second brush may have a hollow stock to supply the blacking or polishing agent. The framework may be on rollers or castors, to render the apparatus portable.—Patent abandoned.

2936 C. MONTAGU. *An improvement in the manufacture of articles of apparel worn on the head by women and children.* Dated October 18, 1867.

Here the material used is caoutchouc or india-rubber, or a compound or compounds of which india-rubber forms the main or principal ingredient. This material is moulded into form, or reduced to sheets or thin pieces, or they may be shaped by other ordinary processes or contrivances, and any ordinary means may be used for removing unpleasant odour, and for imparting polish or colour to either or both of its surfaces. It is cut or formed to the required external configuration, and any desired device or design may be formed on it by suitable cutting tools, or other means.—Patent abandoned.

2937 M. ALEX. *Improvements in davits for ships and other vessels.* Dated October 18, 1867.

These improved davits have joints near the taffrail, so that they may bend over and swing clear of the ship's side while they are lowering or raising a boat or other body. They are provided with swivel joints attached to a plate fitted to the deck or elsewhere, so that they slew in any direction. The plate is connected with a crab winch and screw break or similar contrivances for raising and lowering a boat or other body, and a ratchet wheel and pawl or detent are added to stop the boat or load at any required position.—Patent abandoned.

2938 F. W. WAIDE. *Improvements in the internal decorations of dwelling houses and public buildings, and in the mode of manufacturing and fixing the same.* Dated October 19, 1867.

This invention consists in making such decorations either wholly or partly of cast iron, thereby facilitating the fitting up of the same, and affording great scope for elaborate and durable ornamentation at a small expense. In making these decorations the patterns are made in one or more parts, and of any convenient length, and the castings are nailed or secured to the walls or ceilings, or to both. The improvements in making ceiling centres consist in making the pattern in radiating segments, so that the entire centre can be cast from a small sectional pattern.—Patent abandoned.

2939 M. J. MATTHEWS. *Improvements in pianofortes.* Dated October 19, 1867.

This invention has principally for its object to obtain in pianofortes, by an improved construction, a greatly increased stability of the case or frame which resists the strain due to the tension of the strings, together with additional power and improved quality of tone. The principal features of novelty comprised in the invention are, first, the disposing of the strings in duplicate, or in two sets arranged back to back, as it were, those on one side thus resisting and balancing the tendency which those on the other side have to bend the frame, combined with the adaptation to such duplicate strings of one or more, and by preference two, sound boards held in position solely by the pressure of the strings. Secondly, the fixing of the bridge pieces, or some of them, on the sound boards; and, third, the application of such duplicate strings of corresponding duplicate hammers arranged to be actuated by means of one set of keys, or by means of two sets of keys.—Patent completed.

2940 W. LIEBERMANN. *Improvements in the construction of churns.* Dated October 19, 1867.

This invention relates to certain improvements in the construction of churns whereby butter may be made in a few minutes, the churns being self-acting. The inventor proposes to set on a framework supported on standards a hollow drum of wood, capable of turning vertically on a horizontal shaft placed and rested in bearings on the frame; one end of the shaft or axis is provided with a pinion or small-toothed wheel which is furnished with a toothed ring gearing into the teeth of the pinion. A box containing a spring is employed, the bearing of this spring box being also in the frame at the side of the pinion. The drum has an aperture at the top fitted with a hinged lid and fastening, by which means the cream to be churned is supplied to the drum; the spring having been wound up by a winch handle fitting a square or triangular spindle, the drum, which is previously secured to the frame by a hook, is released, and is caused to rotate rapidly by the power of the spring, which is to be of such length as to continue turning the drum for about six or seven minutes, when it will be found that the cream has been converted into butter.—Patent abandoned.

2941 W. R. LAKE. *Improvements in breech-loading fire-arms.* (A communication.) Dated October 19, 1867.

This invention relates, first, to breech-loading mechanism of novel construction for firearms, the breech of which is closed by a cylindrical block fitted to slide endwise in a chamber at the rear of the barrel. The block is provided with a catch or projection extending from its surface, and when the breech is closed, the block is turned upon its axis, so as to bring the said catch in front of a shoulder on the breech chamber, the block being thereby kept securely up to the breech. In opening the breech, the catch is turned back into line with a longitudinal aperture, which allows the catch to pass, and the block to be drawn back. The cartridges are ignited by the blow of a firing pin which passes through the cylindrical block, and is driven forward by a spring held by a catch, from which it is released by means of an ordinary trigger. The said improvements may be said to consist, chiefly, in the peculiar construction and arrangement of the main spring and in the devices employed in connection with the trigger for holding and releasing the said spring. The invention relates, second, to certain improvements in needle guns, more especially those known as the "Chassepot" gun. The details are voluminous.—Patent completed.

2942 A. F. JALOUBEAU and C. L. LARDY. *Improvements in the construction of telegraphic cables, and in the apparatus for the manufacture thereof.* Dated October 19, 1867.

These improved cables are constructed in the following manner:—The copper conducting wire is first covered with bituminously prepared thread or twine; the cable thus formed is then subjected to a hot bituminous bath, by which a layer or deposit of bitumen is obtained; this is covered with bituminously prepared paper wound spirally round the cable; it is then again subjected to the bath and a second layer of bitumen deposited thereon, after which it is again covered with the paper, as before, and then coated with bitumen by means of the bath; then another layer of paper, then a layer of bitumen, then a layer of paper, then a layer of thread, as before, and finally a casing of bitumen, which is sanded all over; and in cases where it is desired to make a more powerful cable, it may be strengthened by iron bands wound in a spiral form round it; this is done previously to the final coating and sanding. The cables thus manufactured are flexible and solid, whilst at the same time, the wires, being perfectly insulated, have all the necessary conducting properties, and from the simplicity of the manufacture, and the materials employed therein, have considerable advantage over those in present use. The apparatus employed is not described apart from the drawings.—Patent completed.

2943 L. NEWTON and J. SWAILES. *Improvements in corks or stoppers for bottles, and in machinery for manufacturing the same.* Dated October 19, 1867.

The patentees claim, first, corks or stoppers for bottles or other vessels with flat-sided or round, milled or fluted heads, as described. Second, the combination and arrangement of mechanism for forming at one operation in each spindle one or more of the head parts of corks or stoppers, as described. Third, the improved modes of gripping and holding the blank, and of holding and fluting the blank, so that it will rotate with the spindle and also the mounting of the reducing tools directly upon the end of the lever, actuated by the cam, thus dispensing with the slide, as described. Fourth, the combination and arrangement of the mechanism for making the head parts of corks or stoppers, as described. Fifth, the modes of fluting or milling the heads of corks or stoppers, as described. Sixth, the arrangements for facilitating the dipping of the point ends of the head parts of corks or stoppers into the cement, as described. The details of the invention are too voluminous to be quoted here.—Patent completed.

2944 J. SCHWARTZ. *Improvements in cooling or refrigerating water.* Dated October 19, 1867.

The patentee claims the mode of and apparatus described for cooling or refrigerating water by subdividing it or dividing it up into drops or thin films or streams, so that the heat may more readily escape or be abstracted therefrom, as set forth.—Patent completed.

2945 F. ADKINS. *Improvements in the manufacture of hoes.* Dated October 19, 1867.

This invention consists in manufacturing hoes, whether of iron, steel, or steel iron, or iron and steel, or any of these metals combined, by rolling strips, sheets, or bars of such metal or metals into a form to make, when cut into shapes, the article required to be produced.—Patent abandoned.

2946 J. ANDERSON. *Improvements in the manufacture of felts, and in machinery connected therewith.* Dated October 19, 1867.

This invention relates to the manufacture of the materials commonly known as sheathing, inodorous, and roofing felts, and consists, first, in coating or covering one or both of the surfaces of such felts, after they have passed through the ordinary process of manufacture, with a thin layer of the native mineral pitch, commonly known as asphalte, or other bituminous substance, so as to render unnecessary the painting or coating thereof by means of brushes, as ordinarily practised when such felts have been applied to use. The means employed for so coating or covering the surface or surfaces of the said felts consist in passing such felts over or under a cylinder or cylinders attached to or in connection with the ordinary machine, and during their passing they receive a coating of the said substance, which percolates or flows through a long narrow slot in, or is lifted by, the cylinder or cylinders out of, or is otherwise conveyed from, a box or pan filled with the said substance, and placed over, under, or at the side of the cylinder or cylinders. And the invention also consists in covering or dusting the surface or surfaces so coated as aforesaid with the refuse of flax or card waste, commonly known as shives, in order to give the material a light colour, and to prevent the coating above described from adhering to anything with which it may be brought into contact.—Patent abandoned.

2947 E. BUTTERWORTH. *Improvements in machinery for preparing and spinning cotton or other fibrous substances.* Dated October 19, 1867

This invention consists, first, in an improved apparatus for driving the bobbin shafts of slubbing, intermediate, and roving frames. In performing this part of the invention, the inventor fastens a bevel wheel on one of the bobbin shafts, which is driven by a bevel wheel on one end of a diagonal or cross shaft (which shaft is carried by a frame, one end of which frame is supported by the lifting rail or slide, and the other by a fixing stud or shaft that is concentric with the wheel that drives the diagonal shaft); on the other end of this diagonal shaft is another bevel wheel, which is driven by a wheel fastened on the boss of the "Jack-in-box," as usual. This wheel he makes with the teeth to face the teeth in the wheel on the bobbin shaft first mentioned. The second part of the invention consists in making the shafts, studs, or bosses, on which revolve the "Jack-in-box" wheels of slubbing, intermediate, and roving frames, hollow or smaller in diameter for a portion of their lengths, so as to form a reservoir for oil. The third part of the invention relates to the drawing rollers of slubbing, intermediate, or roving frames, or other preparing or spinning machines. These have formerly been made of steel, or iron not hardened; but this invention consists in making them, or the surfaces of them, of hardened steel or iron, or other material which cannot easily be dented.—Patent abandoned.

2948 M. W. SHOVE. *Improvements in the construction of letter boxes, pillar letter boxes, and money and other such like boxes.* Dated October 19, 1867.

The patentee claims, first, the combined arrangement of certain plates acting together in the manner described; and, secondly, attaching an alarum to a letter-box so that it shall be caused to sound each time that the flap or letter plate of the box is opened.—Patent completed.

2949 R. WATKINS. *Apparatus for discharging projectiles from vessels or forts below the water line.* (A communication.) Dated October 19, 1867.

Here the patentee employs a tube of bronze, or any other suitable material, of a suitable length internal bore and thickness. This he mounts in two or more bearings to permit of its being slid or moved longitudinally therein by means of a rack and pinion, or mechanical equivalents therefor. One end of this tube or conductor is fitted to the muzzle of the gun, to which it may be securely fixed. The bore of the tube and that of the gun may be of the same diameter and coincident. The other end of the tube or conductor is fitted with a plug or cap piece. Thus the tube or "conductor," when attached to the muzzle of the gun, will form a continuation or elongation of the gun itself. Near to the gun end of the tube or "conductor" he prefers to employ or fit a sliding or other convenient form of shut-off valve for the purpose of preventing water entering the muzzle of the gun after each discharge, and the valve may either be closed by hand, or by means of the recoil of the gun, or by a spring or weighted lever. A cock or union and valve may be fitted to the lower side of the tube for the purpose of drawing off any water that may be therein; also for the purpose of effecting a connection with an air pump, or other exhausting apparatus. Reference to the drawings is essential to a full description of the invention.—Patent completed.

2950 H. HUGHES. *Improvements in the manufacture of ornaments for dresses and decorative purposes.* Dated October 19, 1867.

This invention consists, essentially, in combining with a skeleton frame, having depending edges and pins or points, a piece of velvet or other desired material, the edges of this material being held within the edges of the frame, and the metal pins serving to secure the whole to a dress or other article.—Patent abandoned.

2951 M. B. NAIRN. *Improvements in power looms.* Dated October 21, 1867.

This invention has principally for its object, by an im-

Digitized by Google

proved construction, to render power looms suitable for weaving very wide and heavy fabrics, such as floorcloth canvas of, for example, eight yards in width, and the principal features of novelty are—first, the actuating of the lathe by cams which keep it back for a length of time sufficient for the passage of the shuttle, and allow it to beat up by the action of gravitation alone or combined with springs; second, the actuating of the picking levers also by gravitation, by means of weighted levers which are raised and let fall by cams; and, third, the arranging of the driving gearing in duplicate at the two sides of the loom. —Patent abandoned.

2952 W. CROSSLEY and T. C. HUTCHINSON. *Improvements in the manufacture of alumina and salts of alumina from blast furnace slag or from other silicates of alumina containing all excess of lime or magnesia.* Dated October 21, 1867.

This invention consists in certain improved processes for the manufacture of alumina and salts of alumina by means of the decomposition of blast furnace slag, or other silicates of alumina containing an excess of lime or magnesia.—Patent completed.

2953 W. BARRETT and C. MARTIN. *Improvements in tuyeres for blast furnaces and other purposes.* Dated October 21, 1867.

Tuyeres constructed in accordance with this invention are formed of heavy piping, such as is used for Perkins's well-known hot water apparatus, the same being made into a coil of the desired size. The pipes are arranged as flow and return pipes, and commence at and return to any convenient positions, at which they are connected together and placed in the form of a coil or otherwise in a cistern or reservoir of cold water when required for use; the pipes are previously charged with water, such space as may be necessary for its expansion being left therein. As the water passes down the flow pipes to the nozzles, it becomes heated, and rises again through the return pipes, and having been cooled by passing through the cistern or reservoir of cold water, again descends, the tuyere pipes being thus constantly charged with a circulating current of water.—Patent completed.

2954 C. D. ABEL. *Improvements in screw bolts and nuts for securing fish plates and other objects.* (A communication.) Dated October 21, 1867.

This invention consists in constructing screw bolts with two threads of a different pitch, and with square or polygonal ends of equal dimensions with or less than the other part, whereby to turn the bolt. These bolts are provided with two nuts, one at each end, each nut having a thread of a pitch corresponding to the thread of that part of the bolt on which it fits. These nuts are so formed that they cannot turn.—Patent abandoned.

2955 J. HUNTER. *Improvements in the permanent way of, and in signalling on, railways; also in lubricating the axle and other bearings of the engines and other carriages of railways.* Dated October 21 1867.

This invention is not described apart from the drawings. —Patent completed.

2956 J. CLAPIER. *An hygienic pillow (Parisian).* Dated October 21, 1867.

The distinctive character of this invention consists, first, in the use of metal plates, bare or covered, of cane, whalebone, or hooping formed into a sort of trellis work cage, containing springs, and permitting air to circulate freely within it. Second, in the style of the cushions fastened together by a lacing through metal or other eyelet holes by ribands, cords, buttons, or clasps set far enough apart to permit air to pass freely into the cushions or coverings applied on the trellis-work cage above described. Third, in the style of the feather cushion with even covering stuffed in compartments closed by platbands sewn or glued, the effect being that the down cannot pass from one compartment into the other.—Patent completed.

2957 A. H. BRANDON. *An articulated artificial leg.* (A communication.) Dated October 21, 1867.

This invention is not described apart from the drawings. —Patent completed.

2958 C. DUNCOMBE. *Improvements in apparatus for charging and closing breech-loading cartridge cases.* Dated October 21, 1867.

We cannot here give space to the details of this invention. We shall probably describe and illustrate it in a future number.—Patent completed.

2959 H. HUGHES. *Improvements in bottles and other like receptacles, and in apparatus for stoppering and unstoppering the same.* Dated October 21, 1867.

This invention—so far as it relates to bottles and other like receptacles, such as preserving jars and others—consists in forming an aperture transversely through the neck extending through both sides in addition to the ordinary vertical aperture. This transverse aperture may be square, round, or of other convenient shape in section; it is preferably tapered, and is intended to receive a cork or stopper for closing the mouth of the bottle or receptacle. The ordinary vertical aperture is then only used when filling or cleaning. The apparatus for stoppering and unstoppering bottles and like receptacles having these transverse apertures consists of a ring or cap to fit over the neck of the bottle; this ring or cap is provided with a nut through which a screw passes; this screw has at its inner end a button or plug which, as the screw turns, is pushed in or out; the outer end of the screw is provided with a handle. In corking or stoppering, the cork or stopper is inserted into the transverse aperture; the stoppering apparatus is then applied, and by turning the screw the button drives the stopper in tight. To unstopper, the apparatus is applied at the opposite end of the stopper.—Patent abandoned.

2960 W. R. LAKE. *Improvements in electric telegraph apparatus.* (A communication.) Dated October 21, 1867.

This invention relates, chiefly, to the construction of recording or writing instruments wherein the pen or marking point is attached to a magnet which is supported in fluid contained in a suitable vessel surrounded by coils of insulated wire. An electric current passing through these coils moves the pen or marker into contact with the surface of a strip of paper or other material which is caused by clockwork or mechanism to travel past the point of the pen. The magnet may either be supported in the ink or other marking fluid, or in alcohol, or other liquid, the ink or other marking fluid being contained in a separate reservoir attached to the pen, or otherwise arranged. The specification of the invention comprises much detail which we cannot devote space to here.—Patent completed.

2961 J. ADAMS. *Improvements in the construction of breech-loading revolver firearms.* Dated October 22, 1867.

The patentee claims, first, the construction and application of a movable shield to the cylinders of breech-loading revolver firearms, as and for the purpose described and set forth, or any mere modifications thereof. Second, the combination and arrangement of the several parts, and mechanism described and set forth, for the purposes aforesaid, or any mere modifications thereof. The details of the invention are voluminous.—Patent completed.

2962 T. WEBB. *Improvements in the construction of sewing machines.* Dated October 22, 1867.

Under the first head of this invention the patentee connects to the shuttle carrier a bar in the form of a cross, the ends of the said bar being supported by and guided in rectangular-shaped holes or pieces fixed to or formed upon the under side of the bed-plate of the machine, and crosswise thereof. The middle portion of the bar has a long slot or opening formed therein, into which a pin takes, the pin being fixed in a disc of metal fastened on to a spindle mounted in bearings, and revolving at right angles to the shuttle bar before mentioned underneath the bed-plate of the machine. He connects this bottom motion with another spindle or top motion for actuating the needle bar and feed, either by means of pulleys and an endless band, or a train of wheels. The needle bar is worked by a pin fixed in a cam or eccentric fastened on the top spindle, and the said pin takes into a slot of a heart shape, or somewhat resembling that shape, and formed near the upper end of the needle bar, so that as the before-mentioned disc of metal revolves, the pin therein will lift up and force down the needle bar and needle at the proper times, the shape of the heart-shaped slot being such as to allow the needle bar to pause whilst the shuttle is passing through the loop of the stitch. The cam or eccentric above-mentioned is also employed to work the feed bar for advancing the work to be sewn, and for holding the work firmly whilst it is being sewn, and to release it at the proper time; or the feed bar may be worked from the bottom motion if desirable. The machine may either be worked by a treadle or by hand.—Patent completed.

2963 C. RITCHIE. *Improvements in tobacco pipes.* Dated October 22, 1867.

This invention has reference to all pipes having two bowls, one inside the other, and consists in applying to the inner bowl a rim or collar of meerschaum, wood, or other material suitable for the purpose, which is fixed to the inner bowl, but separate therefrom, whereby the inner bowl can be removed at all times with perfect ease whenever it may be desired so to do.—Patent abandoned.

2964 T. LEMIELLE. *Improvements in fans for the ventilation of mines, or for propelling air into furnaces, or for other purposes.* Dated October 22, 1867.

This invention relates to a former patent granted to the present patentee, dated 8th May, 1854 (No. 1031), which consists in the employment of a circular outer case, within which, and situated eccentrically to the axis thereof, a cylindrical or hexagonal case, capable of rotary motion, is provided with rectangular vanes, called doors, hinged to the outer surface of the said cylinder, or to the angular points of the hexagonal case. The object of the present invention is to prevent the entrance of air into the eccentric cylinder above described, and thence its return into the mine or other place, either between the covering of the ventilator and the upper and lower ends of the said eccentric cylinder, or through the slots or apertures in the said eccentric cylinder through which the connecting rods pass to the vanes or doors. The details of the invention are too voluminous to be produced here.—Patent abandoned.

2965 P. and A. WALKER. *Improvements in shoes for horses and other animals.* Dated October 22, 1867.

The object here is to render unnecessary the use of nails, and to give ease and freedom to the horse's feet. Each shoe is provided with a projection standing up at or near the front thereof, and lying against the front of the hoof for receiving, by a catch connection, part of a band of iron or other metal. This band thence passes round the lower part of the wall of the hoof to the back thereof, and at its ends is by nuts and screws secured to lugs or projections standing up at the back ends, or the heel of the shoe, in order that the band may be tightened to the extent desired to retain the shoe in position on the foot.—Patent abandoned.

2967 G. JONES. *Improvements in mounting or applying wheels to road carriages of all kinds.* Dated October 22, 1867.

This invention consists in means of mounting the wheels of road carriages so as to reduce the friction on the axle to a minimum, and consists in forming the nave of the wheel, through which the fixed axle runs, with two annular fixed collars, and about one-fourth of the distance from each end of the opening. On the outer of each of the annular rings is placed a number of anti-friction rollers, which encircle the axle, and have their axes in line with the stationary axle which they surround, and the bearings of the anti-friction rollers are formed in a pair of rings which are together and connected parallel by short studs dispersed at equal distances between the rollers, so as to insure the unity of motion of the several parts of the anti-friction rollers. The inner end of the fixed axle is formed with an annular collar, and is provided with a plate or loose disc surrounding the axle, but which is secured by nuts and bolts, or in any other convenient way to the nave, thus preventing the travelling wheel being drawn off its fixed axis. The outer set of rollers may be held in position by a screwed cap or cover, or in any other convenient manner.—Patent abandoned.

2968 J. WHITE. *Improvements in means for ventilating buildings and other places.* Dated October 22, 1867.

This invention relates to means for withdrawing vitiated air from a room or enclosed space. For this purpose the patentee forms apertures in the ceiling of the room or enclosed space, and he employs suitable channels or passages communicating therewith, and with a chamber connected with the grate or fireplace employed to warm such room or enclosed space, and from such chamber a pipe or channel is carried a short distance up the flue. Thus, by the heat generated by the grate or fireplace in the chamber connected therewith, the air contained in such chamber is rarefied, and in passing off by the flue such rarefied air carries away with it the vitiated air from the room or enclosed space. The vitiated air passes through the apertures in the ceiling, and by the channels or passages into the chamber connected with the grate or fireplace, and out thereof through the pipe into the flue.—Patent completed.

2969 W. BEALE. *A telescopic apparatus applicable as a temporary or stationary observatory for temporary bridges, building, and other purposes.* Dated October 22, 1867.

This apparatus consists of a telescopic column or columns arranged upon and adapted to a base or framework, the base or framework being provided with wheels for the purpose of moving the apparatus from place to place. Wheels, pulleys, chains, and other parts or contrivances, are employed in working the apparatus.—Patent completed.

2970 H. W. SAMBIDGE. *Improvements in sliding gasaliers, chandeliers, and other pendent lamps.* Dated October 22, 1867.

This invention consists in dispensing with the ordinary water joint by the substitution of a solid boss or carrier upon the outer tube, which boss or carrier is for the purpose of sustaining the balance weight chains. Two tubes only are employed, one sliding within the other, and above the boss or carrier is fitted a gland or stuffing-box through which the inner tube works.—Patent abandoned.

2971 A. V. NEWTON. *An improvement in dredging and spice boxes.* (A communication.) Dated October 22, 1867.

This invention consists, simply, in forming a group of lateral perforations in one side only of the cap or covering of the vessel containing the powdered materials to be sprinkled, whereby the act of sprinkling or discharging the materials is easily and conveniently performed by holding the vessel in a horizontal position.—Patent completed.

2972 W. GRAY. *Improvements in the manufacture of file blanks, and in the machinery or apparatus employed therein.* Dated October 22, 1867.

This invention relates to the rolling of file blanks of all shapes and sizes required by the trade, in lieu of forging the same by hand labour, and consists in the employment for that purpose of rolls to which are attached or fitted plates and collars of steel, wrought iron, chilled cast metal, brass, or other suitable metal or alloy, such plates and collars being specially formed and adapted for the production by rolling of file blanks.—Patent completed.

2974 J. HADDOCK. *Improvements in the construction of shuttle tongues.* Dated October 23, 1867.

This invention consists in uniting the shuttle tongue to the head or tumbler by means of a spring, or some other analogous contrivance, so that, when the shuttle is stopped by the swell, or the nose of the shuttle is struck by the picker, the shuttle tongue, with the cap upon it, can yield, and thus the liability of knocking the cap off, or loosening it, is avoided.—Patent abandoned.

2975 C. D. ABEL. *Improvements in the means and apparatus for pulverizing substances more particularly applicable to the pulverization of materials for porcelain paste.* (A communication.) Dated October 23, 1867.

The patentee claims pulverizing materials for porcelain paste and other substances by introducing them together with balls of glass or porcelain inside a revolving porcelain cylinder, arranged and operating substantially as described.—Patent completed.

2976 T. WELTON. *Ozonized or oxygenated bread, biscuits, cakes, and other substances.* Dated October 23, 1867.

This invention relates to a new process for curing disease in man and animals by means of charging the food with ozone, oxygen, or other gases as found most suitable, and also for rendering that food more nutritious, and more capable of sustaining animal life. The inventor uses, by preference, vegetable substances, either in their raw or cooked state. It is probable that an extension of time for completing this patent will be petitioned for. It is at present in that stage to which we append the words —Patent abandoned.

2977 F. J. BUGG. *Improvements in the manufacture of pressed leather.* Dated October 23, 1867.

Here the patentee employs in the manufacture of pressed leather (which is made from curriers' shavings, &c.), a cementing material which is not soluble in water, and he dissolves it for use in a suitable solvent. India-rubber and shellac may advantageously be employed as cementing materials in this manufacture, and they may be dissolved for use in naphtha or turpentine, but other cementing substances not soluble in water may also be used with appropriate solvents.—Patent completed.

2978 F. SEILER. *Improvements in apparatus for compressing air, and for working pneumatic railways.* Dated October 23, 1867.

This hydro-pneumatic apparatus is an improvement upon certain single-acting hydro-pneumatic apparatus, invented by the present inventor, a modification of which has been, and is now, employed in connection with the Mont Cenis railway tunnel for supplying the compressed air for the rock-boring machines, and for renewing the air in the tunnel. The details of the invention are too voluminous to be produced here.—Patent abandoned.

2979 C. S. JEAFFRESON. *Improved apparatus for treating fractures of the limbs.* Dated October 23, 1867.

This invention consists, principally, in substituting for the pads ordinarily employed bags or pads of india-rubber, waterproof cloth, or other suitable impermeable material. These bags are provided with tubes and nozzles by means of which they are inflated with air, or filled with water, as may be thought most desirable. They will then fit exactly to the limb, and will give an equal pressure at all parts.—Patent abandoned.

2980 A. M. CLARK. *Improvements in steam governors and valves.* (A communication.) Dated October 23, 1867.

This invention relates to centrifugal ball governors for regulating the motion of steam engines, waterwheels, and other machinery, and they consist, first, in a device for controlling the action of ordinary ball governors, so that they shall more perfectly perform their function as regulators of machinery to make the motion uniform and steady. This object is accomplished by providing a lever in connection with the governor stem, which is actuated directly by the pressure of the steam upon a small piston in a pipe leading from the boiler, and also other devices connected therewith, whereby the closing and opening of the valve is exactly graduated, and the steam cut off entirely by an instant closing of the valve in case of accident or interruption to the machinery. Second, in a device to be applied to governors for the purpose of preventing the joints and valves from gumming or becoming rough and dirty with scale and oil, causing them to work stiff. This improvement consists in stopping the governor spindle in the

Digitized by Google

valve stem in such manner as to produce a bobbing or saltatory motion, which keeps all the parts moving continuously, and thereby always in good working condition. Third, in forming the valves and valve seats with chilled rubbing surfaces to prevent cutting and wearing away.—Patent completed.

2981 J. L. NORTON. *Improvements in sinking or forming wells, and in apparatus to be used for this and similar purposes.* (Partly a communication.) Dated October 23, 1867.

The patentee claims driving a well tube by means of a weight or driver guided in its rise and fall by the well pipe itself, or by a guide or lengthening bar carried thereby. He also claims employing a ring clamp capable of being fixed on the tube at any part of its length to receive the blows of the weight or driver. He also claims the construction of the said clamp in the manner described. He also claims employing a ring clamp fixed on the tube, or on a lengthening bar carried thereby, to carry the pulleys for the ropes or chains to lift the weight or driver. Also he claims carrying these pulleys, and steadying the upper end of the pipe, by means of a tripod, or similar support. Also he claims applying springs to maintain a strong downward pressure on the well tube whilst it is driven by the blows of a weight or driver. Also he claims a tube perforated at its lower end, and with a screw thread upon it, externally applied, to produce a well in the manner described. Also he claims the application of springs in a similar manner when driving piles and exploring tubes. Also he claims clearing the soil from the interior of the well tube by the introduction within it of a smaller tube having a pump applied and worked so as to draw up the soil together with the water poured down the well tube. Also he claims forcing water down the well tube, both to lubricate it during the driving and also to form passages to the water-bearing strata.—Patent completed.

2982 A. CHAMBERS. *Improvements in machinery for the manufacture of files.* Dated October 24, 1867.

The specification of this invention is too elaborate to be quoted here at sufficient length for an intelligible abstract. It is probable that an extension of time for completing this patent will be petitioned for. It is at present in that stage to which we append the words—Patent abandoned.

2983 H. R. ST. MARTIN. *Improvements in ornamenting transparent, or partially transparent, glass.* Dated October 24, 1867.

This invention consists, first, in subjecting those parts of the transparent or partially transparent glass which are to be covered by the intended ornamentation to the action of any suitable acid, whereby such parts may be eaten away to a depth equalling the thickness of the parti-coloured transparent glass to be used in the composition of the ornament. The various pieces of coloured glass are then inlaid in their prepared bed, according to the various lines presented by the object, design, or device intended for representation. The pieces of glass thus inlaid and arranged may be fixed and retained in their proper position by any convenient means, such, for instance, as the use of some agglutinative matter, as copal, amber, or other varnish, or by placing a sheet of transparent glass so as to rest on and cover the whole surface of the ornament, or by a combination of such methods. Second, the pieces of coloured glass intended under various forms and in various combinations for the species of ornamentation which the inventor has indicated, instead of being cut into their required shapes, may be produced in any form from sheets of coloured glass in a similar manner to that referred to for inlaying glass. But instead of only eating away the glass to a certain depth by the application of appropriate acid, the inventor proposes to eat through the entire thickness of the coloured glass surrounding the outline of the traced figure. Third, he proposes to affix pieces of transparent parti-coloured glass, having either flat-faceted or curved external surfaces upon a sheet or sheets of transparent glass, the pieces of parti-coloured glass being so formed and arranged as to present various objects, designs, or devices.—Patent abandoned.

2984 F. GERHARTZ. *Improvements in the manufacture of manures and disinfectants.* Dated October 24, 1867.

This invention relates to the preparation and use of charcoal obtained in the manner described in the specification of this invention in the manufacture of sugar from beet root. The details are voluminous.—Patent abandoned.

2985 J. THOM and A. MACLURE. *Improvements in the manufacture of ornamental fabrics.* Dated October 24, 1867.

This invention consists in producing ornamental devices in the weaving process by heddles, harness, or other known means, and in producing the ornamental devices or parti-colourings either by printing the warps, or by printing the weft, or by printing the warps and weft before they are woven.—Patent abandoned,

2986 R. W. THOMSON. *An improved wheel for steam carriages, to be used on common roads.* Dated October 24, 1867.

This invention consists in applying to the wheels of such carriages external bands or tires of vulcanized india-rubber, instead of making such wheels with tires or external treading surfaces of iron or wood, as hitherto.—Patent completed.

2987 J. ELLISON and J. STIRK. *Improved means and apparatus for economizing fuel and consuming smoke in steam boilers and furnaces.* Dated October 24, 1867.

This invention has reference, principally, to Cornish boilers, though applicable to other boilers and also furnaces. The patentees take an old Cornish boiler, for example, which is fired internally within the flue, and behind the bridge they insert an Archimedean screw composed of metal, cast or wrought, or of any other suitable substance. This screw may be of nearly the same diameter as the flue itself, and may extend from the bridge to the end of the flue. The action resulting from the use of it is that the flames from the fire, after passing the bridge, are conveyed equally over the whole internal surface of the flue, by which means the water under the flue in the lower part of the boiler becomes heated (instead of being nearly cold, as is the case in ordinary flues) as well as that surrounding the top and sides. A further result arising from the use of this screw (the vanes of which are supposed to be solid as well as its centre or core) is, that its vanes becoming heated from the action of the flames, the smoke which would otherwise be emitted into the chimney is consumed, consequently the two points of economizing fuel and consuming smoke are attained.—Patent abandoned.

2988 W. E. GEDGE. *A novel kind of nail or tack specially intended for upholstery and cabinet work.* (A communication.) Dated October 24, 1867.

This improved nail or tack is made of brass or of copper, and by casting, so that any desired ornamentation may be moulded on its head, which may then be gilt, silvered, or burnished, as may be preferred.—Patent completed.

2989 G. OLNEY. *Manufacturing and for improving illuminating gas.* Dated October 24, 1867.

The main features of this invention are, first, the arrangement, in connection with retorts, a cooler and a gasometer of carburators provided with tanks, filters, liquor chambers, connecting pipes, an air pump and its connections, an independent air pipe, a liquor pump with pipe, a gas pipe, a steam pipe, a liquor gauge and syphon gauges (as described in the specification), for the purpose of converting carbonihydrons and napthene vapours with atmospheric air into illuminating gas, or for making or producing a fixed or illuminating gas from carburetted air. Second, the injecting of petroleum, or its products, into heated retorts direct, by means of a pipe, and there combining it with atmospheric air, carburetted or not, and thus chemically producing illuminating gas by passing carburetted air through heated retorts. Third, the producing of illuminating gas by combining the carburetted air after having passed through the heated retorts (or within the same) with ordinary coal or oil gas. Fourth, the employment of an oil or equivalent seal as and for the purpose explained.—Patent abandoned.

2990 J. DODGE. *Improvements in machinery for cutting files.* Dated October 24, 1867.

This invention refers, firstly, to file cutting machines in which a shaper is used to regulate the force of the hammer on the cutter, and consists in transferring the weight of the acting spring from the part which moves on the shaper to a fixed point. Second, in the use of an abutment for the cutter, whereby it is prevented from slipping on the blank when the hammer has struck it. Third, the invention relates to loose cutters, and consists in an arrangement whereby they may readily be removed for whetting or other purpose. Fourth, the patentee mounts the cutter with an elastic abutment, in order that, when the hammer presses upon it, it may adjust itself to the blank before the blow is struck. Fifth, he compounds the hammer to make the part which effects the blow adjustable. Sixth, the invention relates to cutting half-round or other such files. Reference to the drawings is essential to a full description of the invention.—Patent completed.

2991 H. ADCOCK. *Improvements in kilns for burning pipes, tiles, bricks, pots, and earthenware.* Dated October 24, 1867.

The patentee claims economizing the heat in kilns for burning pipes, tiles, bricks, and earthenware articles, by causing the waste heat from one kiln to pass into a second, and thence to a third or more kilns, as and for the purposes set forth.—Patent completed.

2992 J. MITCHELL. *Improvements in buffers and draw springs for railway carriages.* Dated October 24, 1867.

The patentee manufactures these articles in a simpler form and more inexpensive manner than heretofore. He dispenses with the ordinary plunger, and instead thereof he forms the spiral spring of a flat broad piece of sheet steel, the outer coil of which, by being made parallel, fits in the fixed box, and acts as a plunger, and instead of the ordinary plunger.—Patent completed.

2993 H. RITCHIE. *Improvements in carriages.* Dated October 24, 1867.

This invention consists in constructing a four-wheeled semi-open carriage in the following manner:—The body of the carriage is made with a rigid head overhanging the back seat, and on this head at the front the driver's seat is formed, and under the driver's seat, to give it a firm support from the fore part of the body, two metal columns are erected; they carry also the coachman's footboard. In front of these columns, and immediately over the locking frame of the fore wheels, on the fore part of the body, is a platform on which luggage may be carried. The interior of the carriage has a back seat for two persons. There may be three outside seats on the head of the carriage, one by the side of the coachman and two behind, with their backs to him.—Patent completed.

2994 S. STACKARD. *Improvements in bottling apparatus.* Dated October 24, 1867.

This invention has for its object the so arranging bottling apparatus that the bottles may automatically, or without requiring the attention of the bottler, be all filled to the required level, and this without involving the exposure of the liquor to the air, as when an open trough is employed, such as is used in other bottling apparatus where the filling of the bottles to given a level is effected automatically. The details are too voluminous to be produced here.—Patent completed.

2995 A. M. CLARK. *Improvements in apparatus for transmitting and multiplying motive power.* (A communication.) Dated October 24, 1867.

This invention relates to a combination of parts forming an improved motor, whereby increased power may be produced and applied. This motor consists of two fly-wheels, independent one of the other, mounted in the same plane, the ends of their shafts being contiguous to each other. Two pulleys are mounted at each end of these shafts, the one fixed and the other loose, and provided with bands by means of which the fixed pulleys are driven alternately for setting the fly-wheels in motion. These four pulleys are of equal diameter, so that the driving bands may be readily transferred from one to the other. The two pulleys fixed one at the end of each shaft are loose, and made only half the diameter of the fixed pulleys, so that the two only have a surface equal to one of the pulleys. These two movable pulleys are so fitted for the purpose of transferring the belt from one to the other of the fixed pulleys without actuating them both at the same time, they being driven at different speeds, as the belt would meet with an obstacle to its motion were it to be placed at the same time on two fixed pulleys having different speeds. This improved motor may be set in motion in different ways, either by means of water, steam, gas, or air engine, or by animal or human power. Reference to the drawings is necessary for a full description of the invention.—Patent abandoned.

2996 J. H. JOHNSON. *Improvements in spinning machinery.* (A communication.) Dated October 24, 1867.

This invention has reference to improvements in the bearings of the spindles of mules, and the spinning machinery, and also to an improved system or mode of and means for lubricating the journals of such spindles. The main feature of this invention consists, first, in the application of oil or other lubricating liquid to the bolster and the step of spindles by means of a saturated fibrous substance, in such a manner as to prevent the waste of the oil and confine its action to the bearings. Second, in the form of a bolster which is so made as to allow the spindles to be removed with great facility. Third, in the mode of affixing the bolster and adjusting it in the line of the axis of the spindle. Fourth, in the shape or contour of the bearings to conform to the direction of the driving band. Fifth, in the substitution of a long bearing for the bottom of the spindle, in place of the common shallow cup or step, for the purpose of securing a more steady motion and reducing the wear of the spindles, especially of those that are driven from the bottom of the upright drum in mules, and have the driving wheels near the bottom of the spindle.—Patent completed.

2997 C. W. HARRISON. *Improved means of preventing incrustation in boilers and other vessels in which water is heated.* Dated October 24, 1867.

This invention consists in combining or connecting by any suitable means the shell of the boiler or vessel with another body which, in their electrical relations, shall be of a differing or opposite polarity or condition the one to the other, or capable of being rendered so.—Patent abandoned.

2998 R. WEARE. *Improvements in, and in apparatus for, the treatment and for the reception of urine and fæcal matter.* Dated October 24, 1867.

Here the patentee employs for the reception and treatment of urine and fæcal matter a vessel, by preference of a cylindrical form, and closed at the top and bottom. Within this vessel is an inner lining; it may be conveniently of perforated zinc; the sides of the vessel are thus double, and the space enclosed is packed full of powdered charcoal and dry earth, or other deodorizing powder. The soil pipe from an ordinary closet pan is connected with the top of the vessel, so that the urine and fæcal matter from the pan are discharged into the interior of the vessel. The more fluid matters then filter through the deodorizing material into channels which are formed for it against the outer sides of the vessel, and which are perforated, and these channels lead the fluid matters to a small pipe connected with the bottom of the vessel, and with a drain.—Patent completed.

2999 E. M. PALLISER. *Improvements in magazines or reservoirs for containing explosive compounds or liquids, and gunpowder.* Dated October 24, 1867.

The magazines consist of tubes of coiled wrought iron, steel, cast iron, or brass or gun metal, either closed at one end with a breech-plug screwed in, or open at both ends, and provided with copper doors to shut off the contents from fire or other explosions. If the breech-plug be used, the threads in the tubes should be in relief, so that the greatest depth of the threads may not encroach on the thickness of the tube.—Patent abandoned.

3000 W. and D. FISKEN. *Improvements in the construction of steam and other boilers.* Dated October 25, 1867.

This invention is carried out as follows:—The boiler, the ultimate form of which is that of an upright cylinder, the patentees construct of a series of sections, each of which somewhat resembles a multiform wedge. They connect these sections at the centre by as many crossties as possible consistent with the free passage of smoke and gas, and they connect them around the outer circle at the bottom by a tube for the reception and equalization of water, placing the junction of this tube in each wedge section above the mud-hole in each, except those in which the firedoor occurs. They also connect the steam space of each wedge section with a common duct, which may be made as large as the known wants of such steam receivers and conductors are known to require. They also connect the different sections in the fireway with cross stays, solid or hollow, or both solid and hollow, which stays have the effect of imparting the strength of the whole to each individual section, whilst the hollow ones will have the effect of adding to the heating surface of the boiler. In addition to the stays in the fireway, stays may be placed in the water space, solid or hollow, or both solid and hollow, by which stays each section will become sufficiently strong of itself. They make the sections as numerous as possible, so that each shall contain as small a body of water as practicable, circulation being secured by the differential thickness of the water exposed to the heating surfaces.—Patent completed.

3001 G. RUSSO and C. A. MACCARONI. *An improved apparatus for saving life and property in case of shipwreck at sea.* Dated October 25, 1867.

Provisional protection has not been granted for this invention.

3002 L. STOCKMAN. *Improvements in the construction of rollers for window blinds.* Dated October 25, 1867.

Here the patentee divides the roller through about the central line thereof into two parts longitudinally (except that he does not usually divide its extreme ends), and he has one half solid and the other slightly hollowed out (except as aforesaid). These parts he connects together by hinges or joints so that action similar to that of a box and lid is obtained. Into the now hollowed part of the roller he fixes a convenient number of small tenter hooks or catches, whereby the upper edge of the blind is to be secured to the roller, and to facilitate the attachment of the blind he prefers to provide the same with eyelet holes corresponding to the said tenter hooks, pins, or catches, and when the blind is secured the two parts of the roller are to be closed together, and then the blind will be tightly held between them, and the two parts are firmly kept in connection by a pin, bolt, lock, or hook and eye, or other suitable fastener.—Patent completed.

3003 G. J. GUNTHER. *Improvements in plating or protecting ships of war, fortifications, and other like structures, and the manufacture of the plates employed therefor.* Dated October 25, 1867.

The objects here are, chiefly, first, that none of those parts of the armour which are exposed to the effects of the enemy's fire shall exhibit any bolt holes, or other similar sources of weakness. Second, that by the shape of the armour plates, and of other necessary parts, and by the mode in which they are put together, the cohesion of all the parts composing the armour may be independent of any backing, or any fastening to any backing, and that thus the improved armour, instead of being by its weight a source of weakness and danger to any structure floating or stationary which it may enclose (or compose), will, on the contrary, contribute in an eminent degree towards the solidity, internal cohesion, and stability of any such struc-

ture. Reference to the drawings is essential for a full description of the invention—Patent completed.

3004 H. WILSON. *Improvements in cocks or valves for discharging water, oil, and other fluids or gases.* Dated October 25, 1867.

This invention consists in an arrangement by which the passage of fluids through cocks or valves is so regulated that no waste can take place through negligence in closing the same. The inventor forms the barrel of the cock with a valve seating inside, through the centre of which a spindle passes on which two valves are fixed at any suitable distance apart, one above and one below the valve seating; under the bottom valve he fixes a spring which rests upon the bottom of the cock and presses against the valve above, thereby keeping it against the seating. On the top of the upper valve rests a flat disc, on the upper surface of which ridges or teeth are formed, which fit into corresponding ridges or teeth formed upon a similar disc which is fixed to the spindle by which the valve or cock is opened. Then, by moving the spindle of the valve or cock either to the right or left, the valve is freed off the seating by the discs, at the same time compressing the spring; as soon as the spindle is released, the spring closes the valve.—Patent abandoned.

3005 W. R. LAKE. *Improvements in carpet linings and in machinery for manufacturing the same.* (A communication.) Dated October 25, 1867.

This invention consists partly in the arrangement of mechanism through which the fibrous material is formed into a bat by being fed up to the surface of a card cylinder, the teeth of which carry the filaments to the surface of a lap-forming cylinder, upon the rotating gauze surface of which it is drawn and formed into a sheet, leaving the cylinder in this form, and passing thence between presser rolls, and between the sheets of paper passing between such rolls. The invention also consists in forming such lining of two strips of paper (receiving the batting between them), one of which strips is wider than the other, so that when they come together with the lining between them the opposite edges of the wide strip overlap the adjacent edges of the other strip in such a manner that they may be folded over and cemented to the said overlapped edges. The invention also consists in the means for applying cement to the edges of the wide strip, and in the mechanism for effecting the folding over of the cemented edges; also in a carpet lining in which the loose fibrous material is secured to a sheet of paper, or between sheets of paper, by cement applied over the surface of the paper. Also in a carpet lining having the paper and loose fibre united in a paper-making machine, or while the paper is in a pulpy or semi-pulpy condition. Also in a carpet lining having the loose filling secured between sheets of paper by cementing together the outer contiguous edges of the paper. Also in a lining having the loose filling secured to or between sheets of paper by rows of stitches or "quilting;" and, lastly, in a lining made of the general size and form of steps of stairs to be used as a carpet pad or lining.—Patent abandoned.

3006 W. R. LAKE. *Improved modes of, and means for, curing, drying, preserving, and packing meat, fruit, vegetables, and other perishable substances.* (A communication.) Dated October 25, 1867.

This invention relates, chiefly, to processes and apparatus for cooling and regulating the temperature of preserving and packing houses; also to warming and ventilating packing houses and other buildings for drying and curing meat, fruit, and other animal and vegetable substances, and for similar purposes. The patentee takes advantage of natural principles for the purpose of cooling air in the several classes of buildings and structures mentioned above. To do this it is necessary that the air to be cooled should be brought into contact either directly with ice, or with a good conducting surface which is cooled by the ice. The latter plan, the patentee states, is far preferable, and he has, therefore, adopted it. The details are very voluminous.—Patent completed.

3007 T. STENNETT. *Improvements in dressing and other bags.* Dated October 25, 1867.

This invention consists in constructing bags, such as "fitted dressing bags," with a box or case at bottom; the lid, which forms the base of the bag proper, is hinged to the box or case, and fitted with a lock or other fastening. The box or case contains drawers at each end, which are secured by springs. The box or case proper is fitted with articles, such as brushes, combs, or as taste or requirements may dictate; the cover is also fitted with articles such as knives, razors, scissors, or otherwise. When the box is open, all the contents are exposed to view. The upper part resembles an ordinary bag, and is secured by a lock, spring-catch, or other fastening.—Patent abandoned.

3008 A. M. CLARK. *Improvements in the mode of obtaining publicity and affording information or amusement.* (A communication.) Dated October 25, 1867.

This invention consists in introducing into skeins or reels of thread, silk, cotton, wool, and into other similar articles, small sheets or slips of paper on which are printed or lithographed either plain or coloured advertisements of all kinds, biblical and moral texts, verses, mottoes, rebuses, fashion plates, charades, songs, pictures of historical personages, views, and generally any printed information that may serve to attract, instruct, or interest the purchaser.—Patent completed.

3009 A. M. CLARK. *Improvements in apparatus for the manufacture of postage stamps and other labels, and for reproducing designs on paper or fabrics, and in the preparation of engraved surfaces to be used therefor.* (A communication.) Dated October 25, 1867.

This invention consists, first, in an improved process of engraving, by means of which a design in relief is obtained on a cylindrical surface for producing a typographic impression, the colours applied being indelible, which result has only hitherto been obtained in copperplate engraving on plain surfaces, and with non-continuous impressions. This improved process of engraving, therefore, consists, first, in obtaining a relief engraving having all the artistic finish desired from which a perfectly identical sunk engraving is obtained. Second, in the application of this sunk engraving, which reproduces with mathematical exactness the lines of the graver, and forms a typographic relief on any suitable cylindrical surface of copper, brass, steel, or other metal. The second part of the invention relates to apparatus for the manufacture of postage stamps or labels, the chief feature in this apparatus being that the impression, instead of being produced by flat plates, as usual, is effected by the aid of printing cylinders prepared or engraved in the manner before described. The same machine may both at once perforate, print, and gum the continuous paper surface. —Patent completed.

3010 P. LOVE. *Improved apparatus for regulating the supply of food to cattle, sheep, and other animals.* Dated October 25, 1867.

This invention is not described apart from the drawings. —Patent completed.

PROVISIONAL PROTECTIONS.

Dated March 23, 1868.

975 H. Paulus, Boulevart de Strasbourg, Paris, merchant. An improved pile-driving engine with modifiable length of stroke of the ram, applicable also to other purposes.

Dated March 25, 1868.

1025 A. P. Price, Lincoln's Inn-fields, consulting chemist. Improvements in the treatment of ores, and in apparatus or means employed therein.

Dated March 27, 1868.

1061 H. Hughes, Bristol, builder, and C. Jones, Wolverhampton, lockmaker. Improvements in locks and keys.

Dated March 31, 1868.

1088 W. Allen, Port-street, Manchester, manufacturer of pumps and valves. Improvements in diminishing valves and steam traps for steam pipes.

1090 M. Hawthornthwaite, clerk, and T. Abbott, plumber, Lancaster. Improvements in taps, cocks, or valves for water, gas, steam, or other liquids.

Dated April 1, 1868.

1103 L. Appleton, Princess-terrace, St. Mark's-square, Regent's Park. An improved method for calculating interest and apparatus therefor.

1108 W. Clissold, Dudbridge Works, near Stroud, Gloucestershire, engineer. Improvements in belt fastenings, which improvements are also applicable to the uniting of parts of harness.

1111 J. H. Dufort, merchant, and D. Gance, mechanician, Boulevart St. Martin, Paris. Improvements in sewing machines.

Dated April 2, 1868.

1118 W. Robertson, Glasgow. Improvements in machinery or apparatus for making mitre or other angular joints. (A communication.)

Dated April 4, 1868.

1138 W. Johnson, Stanhope Villa, Campden Hill, Kensington. New or improved machinery for compressing and moulding coal, peat, clay, and other plastic materials.

Dated April 6, 1868.

1152 J. Dunbar, Vicarage-road, Camberwell, S.E., engineer, and R. Nicholson, Dulwich, S.E. Improvements in the construction and arrangement of machinery or apparatus for supplying coal, cannel, or other substances to retorts or ovens, and for withdrawing the same after distillation; also improvements in retorts, retort chambers, mouthpieces, doors, covers, or lids.

1155 M. A. F. Mennons, Rue de la Chaussee d'Antin, Paris. Improvements in apparatus for the transmission and reception of typographic or autographic telegrams. (A communication.)

1158 J. Perry, Rathdowney Brewery, Queen's County, brewer. Improvements in packing bottles and similar articles, and in cases or holders therefor.

Dated April 8, 1868.

1182 G. H. Palmer, Exchequer-place, Lewisham, Kent. An improved spring brace.

Dated April 9, 1868.

1193 J. Plews, Rosedale Villa, Grove-road, Hounslow. Improvements in steam engines.

1197 J. H. Whitehead, Royal George Mills, near Manchester, woollen manufacturer. Improvements in apparatus for removing soot from the surfaces of heating tubes.

1199 J. Leeming, Bradford, Yorkshire, machine maker. Improvements in looms for weaving.

1201 R. A. Wright, Homerton, Middlesex, engineer. Improvements in heating structures and articles, and in the mode of, and apparatus for, obtaining heat from petroleum and other hydrocarbons, and in apparatus for supplying air to furnaces.

Dated April 11, 1868.

1203 J. Sutcliffe, Bradford, Yorkshire. Improvements in outline maps, charts, plans, and similar other articles for educational purposes.

1205 C. Martin, Chancery-lane, civil engineer, W. Barrett, ironmaster, and T. S. Webb, metallurgical chemist, Norton, Durham. Improvements in the treatment and reduction of titaniferous iron ores for the manufacture of iron, and in the application of slag or cinder produced in such processes.

1209 R. Nicholls, Aldermanbury, City, fancy trimming manufacturer. Improvements in self-attaching buttons or ornaments to be applied to ladies' dresses and such like purposes.

1211 H. A. Archereau, Boulevart St. Martin, Paris, chemist. A new method of obtaining heat and light, and its various applications, and in apparatus connected therewith.

1213 A. Woodcock, Edinburgh. An improved mode of, and apparatus for, suspending pictures.

1217 G. Paton, Kilbirnie, Ayrshire. Improvements in looms for weaving.

Dated April 13, 1868.

1219 J. Rothery, Yorkshire, colliery viewer. Improvements in machinery or apparatus for getting and hewing coal, stone, and other minerals, parts of which improvements are applicable to motive power engines.

1221 T. F. Shillington, College-square North, Belfast. Improvements in reaping and mowing machines.

1225 J. Combe, Kensington-terrace, Great Victoria-street, Belfast. Improvements in breaking, spreading, and drawing flax and other fibrous substances, and in machinery to be used in carrying out such improvements.

Dated April 14, 1868.

1226 C. and S. Hargrove, Birmingham, manufacturers. An improvement in the manufacture of breech-loading actions.

1227 T. Smith, millwright, Tenter-lane, Leeds, T. W. Miller, Birstwith, Yorkshire, and T. Don, millwright, St. John's, Red Hill, Surrey. Improvements in manufacturing wheat and other grain into meal and flour, and in machinery and appliances for that purpose.

1231 J. H. Johnson, Lincoln's Inn-fields. Improvements in saw handles, and in securing the same to saw blades. (A communication.)

1233 M. P. W. Boulton, Tew Park, Oxfordshire. Improvements in apparatus for receiving motion or energy from fluids, and for imparting it to them, and in apparatus to be used for propulsion or in connection therewith.

Dated April 15, 1868.

1235 W. Watts, Turner's-court, St. Martin's-lane, Middlesex. Improvements in mangles.

1236 A. V. Newton, Chancery-lane. Improvements in breech-loading firearms. (A communication.)

1237 G. Glover, Ranelagh-road, Pimlico. Certain improvements in the arrangement and construction of submerged or subaqueous lamps, and in the fluid used in, and adapted to, such lamps. (A communication.)

1238 E. Page, Bedford, engineer. Improvements in firing the tines of harrows and other agricultural implements.

1239 W. S. Fletcher, Bradford, Yorkshire, machine maker. Improvements in machinery for combing or dressing silk, flax, china grass, cotton, and other fibrous substances.

1241 R. Ward, "North of England Advertiser" Office, Newcastle-upon-Tyne. Improvements in machinery for spinning or twisting tobacco.

1242 R. Boby, Bury St. Edmunds, Suffolk, agricultural implement maker. Improvements in the construction of horse rakes.

Dated April 16, 1868.

1243 F. A. Leigh, Rose Garland, New Ross, Wexford. An improved machine for planting potatoes.

1247 W. Callander, Newton-Stewart, Wigton. Improvements in apparatus for filling cartridges.

1248 R. Weir and J. Gray, Glasgow. Improvements in furnaces for burning oil.

1249 H. S. Evans, Bartholomew-close, City. Improvements in taps, valves, or apparatus for measuring and registering the quantity of liquid passed therethrough.

1251 J. Robinson, Creek-road, Deptford, Kent. Improvements in the manufacture of paint.

Dated April 17, 1867.

1253 C. W. Siemens, Great George-street, Westminster. Improvements in electrical apparatus for transmitting signals and for ascertaining the distance of objects, as also in instruments employed in connection with such signalling apparatus. (A communication.)

1254 G. D. Kittoe and P. Brotherhood, Compton-street, Clerkenwell, mechanical engineers. Improved apparatus for refrigerating or cooling worts and other liquids.

1255 H. O. Robinson, Glasgow. An improved screw propeller.

1256 W. Gorman, Glasgow, engineer. Improvements in the manufacture of iron and steel, and in apparatus therefor.

1260 Lieut. F. Bacon, Royal Marine Artillery, Wymondham Rectory, Leicestershire. Improvements in breech-loading firearms.

1262 A. V. Newton, Chancery-lane. Improved machinery for gathering hay and other crops from the ground. (A communication.)

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated April 22, 1868.

1314 W. R. Lake, Southampton-buildings, Chancery-lane. An improved lubricating packing. (A communication.)

Dated April 23, 1868.

1333 W. R. Lake, Southampton-buildings, Chancery-lane. An improved steam cultivator. (A communication.)

Dated April 27, 1868.

1374 V. Delperdange, Brussels. Improvements in the construction and modes of connecting pipes or tubes of metal or other material.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," May 5, 1868.

3645 W. Walker. Cotton ties. (A communication.)
3649 J. Dawkins. Tanning.
3655 P. F. Tranchat. Universal machine for manufacturing circular cutters and milling tools.
3660 F. Render. Traps for pigeon shooting.
3664 G. E. Allshorn. Manufacture of artificial fuel.
3669 N. Greenhalgh, W. Shaw, and J. Mallison. Steaming certain yarns.
3672 E. G. and E. E. Rafer. Braiding machine.
3673 J. Edge. Rag rolls of rag engines.
3674 E. J. Hughes. Blankets used in machines for printing textile fabrics. (A communication.)
3677 J. M. Rowan. Moulds for casting steel.
3679 H. Higgins and T. S. Whitworth. Machinery for spinning cotton.
3680 J. Clarke. Wrappers for needles.
3682 J. W. Lewis. Warming and ventilating apartments.
3701 G. Glover. Lamps. (A communication.)
3703 J. Aschermann. Machine for cutting the hair from skins.
3706 M. A. F. Mennons. Mode of combining the vapours of liquid hydrocarbons with oxygen and hydrogen. (A communication.)
3707 M. A. F. Mennons. Manufacture of a vegetable substitute for animal hair. (A communication.)
3709 T. Messenger. Construction of steam engines.
10 W. J. Fraser. Furnaces.
51 H. M'Evoy. Fastenings for drapery.
58 W. Avery. Needle-cases.
65 B. J. Heywood. Coffee roaster.
70 M. Walker and G. H. Money. Breech-loading small arms.
79 W. E. Newton. Mode of propelling vessels. (A communication.)
116 P. Pittar. Rock drilling apparatus.
128 F. and I. Alckan. Studs.
178 H. Kershaw. Apparatus for spinning worsted.
189 D. Timmins. Motive-power engines.
248 M. Tildesley. Stoves.
282 W. Ellis. Circular machines for cutting wood.
3[illegible] A. M. Clark. Adjustable wrenches. (A communication.)
334 C. H. Adames. Portable metal buckets.
335 E. Fleet. Apparatus for the manufacture of aerated liquids.
417 J. and J. Cash. Machinery for the manufacture of looped fabrics.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, MAY 15, 1868.

TESTING AND ANNEALING STEEL PLATES.

IN describing the effects consequent on punching holes in steel plates for use in shipbuilding, and for other similar purposes, and comparing their strength and adaptability with plates having drilled holes, it becomes a matter of the highest importance to notice the quality of the steel submitted to each of these processes. The highly carbonized plate, or one that is characterized by hardness and density of substance, reveals in its fracture a very fine, bright, granular appearance. This, when closely inspected, is found to contain a well-arranged and well-developed mass of particles, each of which, by the laws of cohesion and affinity, will closely adhere to its fellow, and, being so highly carbonized, and pure, will offer immense resistance and power all the time there is not a leading fracture in any part of the plate. But the exceeding hardness of the particles prevents what is most desirable in a plate subjected to varied strains and fitful action, namely, a certain amount of elasticity, combined with capability of elongation. Thus, while the more inferior particles of a common plate, under heavy strains, have a tendency to overlap each other and blend together, the reverse is the case with the hard plate, the particles of which, refusing to elongate and overlap each other, continue to hold intact their more perfect forms till they suddenly part. This is evident in the process of punching, for the pressure of the punch and die on the metal disturbs and disarranges the particles in the immediate locality of the hole, and creates internal—though imperceptible—fractures.

To illustrate this, we may state that a great number of specimens of steel plates have been prepared and tested at Chatham Dockyard, and although the pieces were so prepared that they should break at the smallest part, they all, without exception, broke at a place where two small holes had been punched. But when the holes were drilled (instead of being punched), and in the largest sectional area of the steel, they all, without a single exception, broke in the smallest part—exactly the reverse of what resulted when the holes were punched. The following is a remarkable illustration of the superiority of the system of drilling holes in armour-plates to that of punching them:—A steel plate was punched and fitted in place on the sides of the "Hercules," recently built at Chatham, and, after having been secured there for several days, it broke suddenly (with a loud report) in the direction of the holes, rendering the plate useless. From experiments which have been made from time to time on different qualities of steel by drilling and punching holes, the advantage gained by the holes being drilled appears to be that the steel plate will stand a higher tensile strain by 22·5 per cent. From what we have stated, it will be seen that there cannot be two opinions as to the superiority of the system of drilling over that of punching holes in steel plates.

Referring to the annealing of steel plates, it has been found by experiment that steel plates annealed, when tried with others in the original condition, give an extraordinary result, for, although holes have been punched in both cases, the pieces which have been annealed have been found to stand a much greater tensile strain than a similar number unannealed, the difference being as much as 60 per cent. It seems, therefore, that annealing lessens the amount of carbon, and the softened particles have a tendency to overlap each other under a tensile strain; but though, doubtless, this is the case, the steel being of a very hard granular nature, has not been found to develope fibre, but still retains its granular appearance. Crucible cast steel, verging towards the quality of fine iron, presents at the fracture a very fine silky appearance, and this description of steel annealed will stand a tensile strain 16 per cent. greater than that which is unannealed, this class of steel being of a very soft nature. Thus the difference between annealed and unannealed crucible cast steel is not nearly so great as it is between steel of a harder nature.

A judicious selection of steel plates is most desirable. Those should be chosen which possess the following qualities, namely, elasticity, capability of elongation, development of fibre under heavy strains, and the possibility of being altered in shape when cold without fracture of surface. It will be seen from the foregoing that punching holes in steel plates injures the metal, and that annealing steel plates of the same quality after being punched improves the metal. The steel plate referred to with reference to the "Hercules" had been punched and cold hammered; the plate in its original condition was of a very hard nature, and evidently had been injured by cold hammering, as well as by punching. The practical conclusion, therefore, is, that the best way to insure against such contingencies is to anneal all steel plates which have been punched or hammered cold before putting them on to the ship, whether such plates be of a hard or soft nature. Thus we have shown that punching holes and cold hammering steel plates not only injures the plate but renders it absolutely useless by its being dangerous to use.

PRESENCE OF OZONE IN THE ATMOSPHERE.

EXCEPT by those who are professed materialists, it will be readily admitted that there are many substances, sensations, and influences which do not admit of tangible proof, although their existence cannot be doubted. It was for a long time suspected that besides oxygen, there was a peculiar modification of that gas exhibited in the air under certain circumstances. In the case of severe storms accompanied with a great deal of lightning, or where a series of electric sparks is passed through dry oxygen or atmospheric air, a metallic odour is at once perceptible. A similar odour can also be obtained by placing some pieces of phosphorus in contact with oxygen slightly damped or moistened. Recent investigations have shown that in addition to the distinguishing odour, ozone possesses some especial qualifications of its own, not common to the other gas. One of these consists in the power it is endowed with of separating or liberating iodine from iodide of potassium. The mere existence of the peculiar smell cannot be regarded as conclusive, for the same phenomenon has been observed in the decomposition of water by electricity, which an undoubted authority has pronounced to be due to the formation of a teroxide of hydrogen, although that substance has never been isolated or obtained in a free state. It is quite possible that there may be two substances which have been confounded under the same name, for whatever may be the cause of the odour during the decomposition of water by the electric current, yet it could not possibly be due, in the case of the passage of electricity through the air, to the formation of a teroxide of hydrogen, as the latter gas is not present.

That there are many different conditions in which oxygen exists in the atmosphere—whether as ozone, teroxide of hydrogen, or other substance—is immaterial, is probably the real solution of the difficulty, and we are inclined to give credit to the views upon this point of M. Houzeau. That able and energetic chemist and savant has classed them under three heads:—Firstly, inactive oxygen, which produce not the slightest perceptible action upon moist ioduretted paper; secondly, oxygen directly active, which immediately imparts a bluish tint to the above description of paper, developing at the same time a peculiar and characteristic odour; thirdly, oxygen indirectly active, possessing no perceptible odour and requiring the aid of another body to affect the test paper. The invigorating nature of country air is presumed to be due to the presence of the second of these modifications of oxygen, which may be regarded as identical with the substance ozone. It cannot be caused by the first description of gas, since inactive oxygen does not affect iodine or its preparations, nor to the third class, since oxygen, indirectly active, requires the aid of an acid to affect the test paper. But the air of the country, although it imparts a bluish tint to slightly ioduretted litmus paper after the lapse of a short time, does not redden the most sensitive litmus, even after it has been submitted to its action for many hours. It effects its complete discoloration but does not redden it. Having demonstrated that the first and third of the presumed modifications of the gas oxygen do not bestow upon country air its peculiar properties, it is but natural, and moreover reasonable, to attribute them to the presence of the second, or ozone proper. Granting this assumption, it is manifest that the odour which invariably betrays the existence of ozone should also be present in the air, and unquestionably so it is. Whenever pure air is respired in the mass, it has not only a distinct smell, but also a distinct colour. It would be in vain to seek for this air in the vicinity of capitals of kingdoms or manufacturing towns, but near the sea side, upon the plains of Salisbury, or out upon the elevated plateaux of the Continent, or the pampas of America, the lungs can appreciate the vital energy they inhale. We would advise all sceptics, who doubt the accuracy of these statements, to first of all familiarize themselves with the smell of diluted ozone or vitiated air, a thing easily accomplished, and then, after sleeping in a close room, to inhale the fresh morning air immediately after rising. They will find that the more the air in the chamber has been contaminated and infected, the stronger and more palpable will be the difference in the odour of the two currents.

In support of his theory, M. Houzeau carried out an experiment, which is at once curious, interesting, and conclusive. Being well aware of the property that flannel and other stuffs possess of condensing in their pores diluted ozone or oxygen, he caused two linen cushions to be prepared of precisely the same material and size, and placed one in the open air, and the other in a room badly ventilated and well filled with company. After the expiration of a certain time he had them both brought to him, and ascertained that the first emitted a distinct odour similar to that of ozone, while the second was completely inodorous. Fresh air in its normal state is endowed with decided powers of decoloration. Litmus and turmeric paper, exposed to its influence and sheltered from the effects of rain, dew, and sunlight, are blanched in a short time, demonstrating that ozone acts energetically as a decolorizing agent. It has long been known as a powerful disinfectant, and could means be devised for procuring it in a free state it would be of the greatest advantage in purifying vitiated atmospheres.

ENGLISH PHOTOGRAPHIC LENSES.

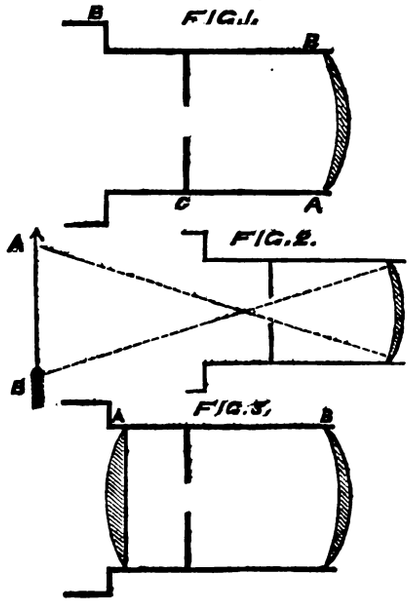
VERY large sums are spent by photographers in lenses, and many instances have come under our notice wherein the purchasers have paid twice as much for their

Digitized by Google

lenses as they are worth. Some of the photographic periodicals have plenty to say on everything connected with photographic lenses except their price. Now, as the majority of photographers are not scientific men, and as the lens is the most important implement in their business, the bulk of them are very considerably in the power of the photographic journals, in the matter of the purchase of lenses; and it is the duty of these periodicals to inform their subscribers why the best photographic lenses in London are now sold at about twice the price of equally good lenses in Paris. This they will no doubt do when they see how very much the ventilation of this subject will promote the interests of their subscribers, but hitherto the fact has been unfortunately overlooked.

Many young beginners and others who are not wealthy would like a little information on the subject of cheap lenses, not to be found in all photographic periodicals. In the early days of photography, pictures of a high class were taken by a lens which did not cost above one or two shillings, and if it could be done then it becomes interesting to enquire why it cannot be done now. The difference between an ordinary and an achromatic single lens is that the chemical and visual foci do coincide in the latter, but do not coincide in the former. That is to say, if the picture thrown by a common lens be brought to a focus by the aid of the eye, upon a sheet of ground glass, it will not be photographically in focus, because the bulk of the photographic or chemical rays come to a point nearer to the lens. To bring these chemical rays into focus with a common lens, the lens should, after focussing with the eye, be pushed nearer to the ground glass, by moving it over a distance of about one-thirtieth of its focal length. Achromatic lenses themselves are only a compromise, for they do not bring all the chemical and all the visual rays to a focus at exactly the same point, and practically the same good photographic results may be obtained with a common lens, by an arrangement hereinafter to be described. In the youthful days of photography, Voigtlander constructed lenses achromatized for the chemical rays only, which were all brought as much as possible to concentrate their action upon a flat glass plate. But photographers would not continue their use, preferring, perhaps wisely—but probably wrongly—to adopt lenses wherein the chemical and visual foci should approximately coincide, though this could only be done at the cost of a loss of intensity of chemical action. Leaving these lenses of Voigtlander out of consideration, there is no advantage in the substitution of an achromatic for a common non-achromatic landscape lens, provided the owner understands the best form and method of using the latter, and does not object to the trouble of pushing in the lens a little after focussing. This movement gives perfect sharpness, and the operator is as well off as if he used the ordinary achromatized lens.

To make a cheap landscape lens, an ordinary circular meniscus "spectacle-eye" should be bought, at a cost of twopence or threepence, or wholesale at a little less than a penny. It should be mounted in a tube of brass or tin, or a pill-box will answer the purpose, but whatever the tube may be it should be blacked inside. The hollow side of the lens has to be mounted towards the view outside the camera, and a stop, consisting of a piece of card or metal with a round hole punched in it, must be placed outside the lens. In the accompanying cut, fig. 1, A is the meniscus lens, B B the blackened tube, and C the stop. If the lens be 1in. in diameter, and the focal length be, say, 6in. or 9in., the stop should be placed about 1in. in front of the lens, that is to say, the best distance of the stop from the glass is usually equal to the diameter of the lens. But the stop may be made movable in the tube to give different effects, and several stops should be provided with holes of different sizes. The same results could not be obtained by using a small lens the size of the hole in the stop, the object of the use of the stop being to cause the sides of the picture to be taken by the sides of the lens, as shown in fig 2. The rays from the top and bottom of the arrow A B cannot reach the centre of the lens, because of the interposition of the stop, but they reach the sides of the lens, and the object just mentioned is gained. The centre of the lens should not be employed to make the sides of the picture. The larger the diameter of the lens, the larger should be the aperture in the stop, and the further should it be placed from the glass. The focal length of the lens and not its diameter determines the size of the plate which it will cover, so that the larger the picture desired the longer must be the focus of the lens. The smaller the stop the longer is the focus. A convenient focal length for landscape lenses for stereoscopic photography is six inches, and if some of our readers will mount a crown glass spectacle lens in the manner here described, and test it against expensive landscape lenses in their possession, they may be astonished at the pictorial results, and find a difficulty in seeing the advantage of using achromatic landscape lenses at all.



So much for a cheap method of obtaining landscape lenses. In portraiture it is desirable to posesss a lens giving a narrow angle of view, and broad pencils, in order to include a large amount of light. A wide angle and flatness of field is not so much required as great intensity and rapid action. In portraiture, therefore, not one, but a combination of lenses is desirable. A well-made achromatic combination is best for the purpose, but good results may be obtained by the use of a simple plano-convex and a meniscus crown glass lens, mounted in one tube, with a stop between the two, as in fig. 3. The front lens A, instead of being plano-convex, may be very slightly hollowed on the side next the stop, that is to say, a shallow meniscus lens will do. The back lens should be a deep meniscus. The front lens should be shorter in focus than the back one. The size and focal length of these lenses depends upon the size of plate they are intended to cover, and experiment is the best course to be adopted by those who wish to try non-achromatized lenses. As a rough guide to those who wish to cover a plate of a particular size, lenses of about the following dimensions may be tried:—

Description of Lens.	Size of Plate.	Front Lens.		Back Lens.	
		Diameter.	Focal length.	Diameter.	Focal length.
	Inches.	Inches.	Inches.	Inches.	Inches.
Stereoscopic.	3 × 2½	1	6	1¼	12
Quarter plate	4¼ × 3	1¼	9	1½	16
Half plate ...	6½ × 4¼	1¾	12	2¼	20
Whole plate	8½ × 6½	2¼	16	3¼	24

The stop, to give sharpness, must be small, so that these lenses are not very rapid in action, but softness combined with depth of focus will be gained by using a large aperture. In fact, these lenses with large stops are capital implements to give the "diffusion of focus" so much in demand of late. Intense definition in one plane only is entirely abolished by this lens, so that in this respect it has an advantage over its more expensive brethren. The time of exposure is governed by the focal length of the combination, and by the diameter of the stop. The larger the stop, and the shorter the focal length, the quicker will be the action of the lens. The effect of slightly varying the distance between the lenses in the tube does not materially affect the results. When the two lenses are placed closer together they cover a larger plate, but the marginal definition is less perfect; whereas, the further separation of the lenses, the more contracted is the field, but the better is the definition. At one time, opticians mounted the two lenses so that the distance between them might be varied at the will of the operator, and the plan was a good one.

Achromatic lenses of foreign manufacture, carefully made and well finished, are imported into England from abroad in great quantities, and sold wholesale, unmounted, at very cheap rates. By purchasing such lenses, and mounting them in home-made tubes, photographers may obtain combinations for various purposes at inexpensive rates, but a good optician is the best man to supply large quick-acting portrait lenses. There are many first-rate opticians in Paris who sell photographic lenses as good in every respect as the best turned out by English manufacturers, and usually at less than half the price, the Parisian optician at the same time gaining a large margin of profit. Such being the case, the assertions of photographic journals to the contrary notwithstanding, it is time to raise the question why a large proportion of their subscribers pay twice as much for lenses as is done by Parisian photographers. When the pictures of M. Adam Salomons beat all those sent to the Paris Exhibition by Englishmen, the photographic journals made a great noise about the fact, and wrote columns on the peculiarities and prices of his pictures. Yet, at the same Exhibition, a foreigner carried off the first prize for photographic lenses, leaving the best English opticians out in the cold; and most of the photographic journals said nothing about the peculiarities of the successful lenses, or their price, although the subject is of great interest to English photographers.

Those photographers to whom these facts may be new are recommended to examine the advertising pages of the particular photographic journal they take in, and learn who are the one or two opticians who advertise most in its pages. Then they are advised to consult the editorial pages during the same period, and see whether the amount of praise given to the lenses exactly corresponds with the length and number of the advertisements. Then other photographic periodicals may be consulted, to see whether or not the same rule also holds good in their pages, with the exception that a different optician may be the head man. After this has been done, it would be well for purchasers not to place the slightest faith, in future, on the praise of any journal, if such can be found, which is seen habitually to mete out its commendations to the largest advertisers, and no others. At the Paris Exhibition, the only silver medal awarded for photographic lenses was given to a French optician, whose charges for splendid lenses are shadows compared with those of some of the English makers. An English optician carried off, also, a silver medal for one particular form of lens, though not for his lenses in general. All the other opticians received only medals of bronze. What is very much wanted is an establish-

Digitized by Google

ment in London where any photographer may send his lenses to be accurately tested, at a moderate fee, and have their working qualities certified in figures. Then, deserving opticians whose names are not known, would soon rise into notice, since the fame of opticians would depend upon the merits of their lenses, and the charges for the same would find their natural level by competition in the usual way. Thermometers are now tested on this principle for a very small fee at Kew Observatory, and the fees clear the expenses.

LORD BROUGHAM.

YESTERDAY week saw the close of the earthly career of a great man. Henry Lord Brougham passed away in sleep, at his villa near Cannes, from a world in which he once and for a long time played a most important part, although of late years he had passed his time in seclusion and well-earned rest. Lord Brougham was born on September 19, 1778, and had, therefore, exceeded the average time allotted to man by nearly a score of years. Although Lord Brougham's biography will find more interest in legal and political circles, still, during his life, he often entered heartily into scientific matters, and, therefore, claims a passing notice at our hands. The more, in that Mr. Robertson, one of the founders of the MECHANICS' MAGAZINE, was associated with his Lordship in the promotion and establishment of mechanics' institutions. In 1825 he published, in the form of a pamphlet, some observations on the education of the people, addressed to Dr. Birkbeck, another coadjutor in the formation of those mechanics' institutes which are now so universal through this country. During this same period he took a chief part in establishing the Society for the Diffusion of Useful Knowledge, and he advocated its cause in the earliest of its publications, issued in March, 1827—a treatise on the pleasures and advantages of science. Later on, he added to numerous publications on a variety of subjects, an edition of "Paley," which he supplemented with two volumes under the title of "Dissertations on Subjects of Science connected with Natural Theology." Lord Brougham took a leading part in matters of education and social science, and in his time did an enormous amount of work in this and other directions tending to improve the condition of the masses. The services he has rendered to his country have earned for his memory universal esteem and respect.

COAST DEFENCES.*

THE American war has proved a fruitful source of practical information upon military science to the profession to which it directly addresses itself, as well as to that of engineering. Several distinguished American officers have laid down the sword and taken up the pen, and have placed on record the results of their experiences in such a form as to prove of inestimable value to military engineers and artillerists. We have had, for example, General Gilmore's excellent treatise on the engineer and artillery operations against Charleston, in 1863. We have now, in the valuable work before us, a treatise on coast defences, by Colonel Von Scheliha, which is based upon the experience gained by officers of the corps of engineers of the army of the Confederate States. It is compiled from official reports of officers of the United States' navy, made during the late war, and extends over the four eventful years during which it lasted. The experience of that war shows that the coast defences and fortifications are insufficient when compared with the means of aggression possessed by fleets. Steam power has rendered ships independent of wind and current, their screws are comparatively safe from an enemy's fire, their decks and sides are protected with armour, and they are armed with few but very heavy guns, the projectiles from which break solid masonry like so much glass. Seeing, then, that vessels of war have thus become altered in their build, their method of propulsion, and their armament, it is not to be expected that they can be resisted by fortifications and defences made to withstand the means of naval attack of past years. During the first two years of the American war, the fleet of the Northern States had great successes in the Atlantic as well as upon the Mississippi. But when the Confederates changed their system of defence and fortification, the Federals had far greater difficulties to contend with, and sometimes did not dare to commence the attack.

In the year 1861, Colonel Von Scheliha, then chief engineer of the staff of General Leonidas Polk, of the Confederate army, was entrusted with the erection of land batteries near Columbus, on the Mississippi. In General Johnston's staff he was sent in the year 1862 to Fort Donelson, after the destruction of which he was sent to erect batteries and barriers at the Cumberland River, below Nashville. In March he joined General Beauregard's staff, and went first to Fort Pillow, then to Island No. 10, both on the Mississippi. At the surrender of the latter place he became a prisoner of war, but was exchanged in August, and became captain of artillery to the corps situated in Kentucky and Middle Tennessee. In January, 1863, he joined General Buckner in Mobile, and was entrusted with the construction of the Alabama and Tonibigbee batteries. In May he was called into active service as chief of staff of the department of East Tennessee. He was promoted after the battle of Chickamanga to lieutenant, and in the autumn was sent to Mobile as chief engineer of the department of the Mexican Gulf. He remained at Mobile in this capacity till the entry of the allied troops, the 12th of April, 1865.

After stating the position he occupied during the war, the author gives the result of his experience in the fortification of coasts, and the entrance of rivers, and the erection of batteries and barriers. The barriers used at Sebastopol were used with great success by the Confederates, with the addition of new methods. For instance, at the entrance to the Bay of Mobile, a torpedo destroyed the armour-plated ship "Tecumseh;" nearly the whole of the crew were drowned. Farragut, who had passed Fort Morgan, dared not attack the town of Mobile, observing that it was impossible to do so with ships so long as the water was barricaded. This is a striking testimony to the value of torpedoes, and a proof that even the iron-plated ships of the present day could not pass the batteries of an enemy, if they were obliged to remain under the fire of heavy guns, by reason of the water being barricaded. In England, Austria, and France experiments have been made for some time with torpedoes, and lately a special torpedo corps has been formed at Toulon, where the importance of these subaqueous mines has been fully acknowledged. According to the experiences of the American war, land batteries should be constructed in conjunction with barriers upon the water, as illustrated in the volume before us, which, we may observe, is furnished with a series of splendidly-executed plans and comprehensive drawings, executed in chromo-lithograph, in Messrs. Spon's happiest style.

The first section of Colonel Von Scheliha's work shows that the progress made in naval architecture and artillery render an alteration of the principles of coast defence imperatively necessary. In the first years of the war the Confederates scattered their forces by trying to fortify every possible point of landing on the long coast line of the Atlantic and of the Mexican Gulf. It would have been preferable to have fortified a few points strongly, with a sufficient garrison and armament, and to have connected the fortifications by railways and telegraph wires. That the strongest masonry cannot resist the monster guns of the present day, and that it should, therefore, always be protected by earthworks, is a fact long known to us with regard to inland fortifications, but it is also the case with coast defences. The bombardments of Forts Sumter, Morgan, and Pulaski show that the strongest walls can be laid in ruins from ships as well as from land batteries, while earth or sand-works suffer but little injury. In 1863, Admiral Porter anchored before the works of Arkansas Port, fired into the trenches, and dismounted the guns. Every shell which entered the trenches and there burst caused immense slaughter among the artillerists. The walls were covered with two trac s of railway, which were torn off and destroyed after a few shots. On the other hand, the land and earthworks of battery Wagner on Morris Island, Forts Fisher and Caswell o Cape Fear, and Fort Powell on the Bay of Mobile, show that earth—and especially sand—works resist the heavy modern artillery far better. The artillerists should be protected by strong shields and coverings, and the garrison should be provided with bomb-proof places of refuge.

No fort of modern construction can hinder a fleet from passing if the water is not barricaded. The coast and river defences in the Northern and Southern States are the same as in Europe. After the first examples, given by the gunboats "Carondelet" and "Pittsburg," in the spring of 1862, at the batteries on Mississippi Island, Farragut passed Forts Jackson and Phillipp below New Orleans, then Port Hudson, and, later, Port Vicksburg, in ships for the greater part constructed of wood, and protected by hay and cotton bales. For several weeks gunboats of the Confederates nightly passed the batteries of the Federals on the Upper Mississippi, below Tiptonville, and the blockade runners passed the blockading fleets during the whole time of the war without sustaining much injury from their fire. That a partial barricading of navigable water is insufficient is shown by Farragut, who, although he lost the "Tecumseh" by the explosion of a torpedo, yet forced an entrance into the Bay of Mobile. He is said to have learnt from spies and deserters from Mobile where there were no torpedoes or where they had been destroyed by remaining too long in the water. An interesting example is afforded of the fact that well-constructed torpedoes may remain for a long time under water without their power of explosion being in the least injured. After the taking of Mobile in the spring, the torpedoes were fished out of the rivers and the bay. One torpedo, however, could not be found, and in the spring of 1866 a merchant ship touched it; it exploded, and the ship was sunk.

That no fleet can pass a fort under the fire of heavy batteries, if the water is barricaded, is shown by Dupont's unsuccessful attempt to enter the harbour of Charleston, in 1863, and Farragut's report to the Minister of War Welles, after he had taken the town of Mobile. He declared it impossible to take Mobile by water, or to enter Spanish River and Choctaw Pass if the entrance were properly barricaded. Colonel Von Scheliha agrees in all important points with Admiral Porter, the first authority on this subject. Porter, besides his experience in former wars, has taken part in nearly all the expeditions on the Mississippi, the Gulf of Mexico, and the coasts of the Atlantic, and is said to be more renowned in the United States, on account of his knowledge and education, than even the brave Farragut. Admiral Porter, in the spring of 1865, sent to the Minister of Marine a memorandum on coast defences, which is given at length in the work

* "A Treatise on Coast Defence," &c. By VON SCHELIHA, Lieut.-Colonel and Chief Engineer of the Department of the Gulf of Mexico of the Army of the Confederate States of America. London: E. and F. N. Spon, 48, Charing-cross. 1868.

Digitized by Google

before us. He considers the fortifications in the Northern States—for example, Fort Munroe and those before New York—as inefficient as most others in Europe, and he recommends fortifications of sand, and iron revolving towers; where there are loopholes of masonry they should be defended by strong iron plates. He says, "barriers upon the water and torpedoes are better defences than our forts," and he recommends the plan which the Confederates have so successfully used. Admiral Porter is by no means of opinion that no fort can resist armoured ships with their monster guns; on the contrary, he says, "The use of land fortifications is not in the least diminished by recent experience; their value is, on the contrary, greater than ever, but they must be suitably constructed." If this is the opinion of the most experienced Admiral of the allied fleet after a four years' war, it ought to be considered as decisive till some European marine has proved the contrary, and has shown that fleets can destroy all land batteries, and can enter places protected by barriers under a heavy fire.

The second section of this important and interesting work treats of the barricading of navigable water. The first condition is that the barriers must be protected by the guns of a battery. Colonel Von Scheliha distinguishes sunken obstructions as follows:—Dams, sunken ships, and masses of rock; posts, trunks of trees, or floating obstructions; chains, ropes with nets, beams, and rafts; and, lastly, torpedoes. These latter are deservedly treated in detail, inasmuch as they were in reality first used in the American war, and with remarkable success. The torpedoes are divided into two classes, viz., stationary torpedoes, which are fastened at short distances below the surface of the water to posts, &c., and floating torpedoes, which are anchored according to the strength of the charge at depths of from 6ft. to 12ft. below the surface of the water. They can be discharged by friction, percussion, or galvanic apparatus from the shore. The torpedo boats and rockets for offensive operations were used with very little success. Colonel Von Scheliha rightly places but little confidence in torpedo boats which approach the enemy's ships under the surface of the water; they can only be moved very slowly, and the men are placed in great danger. The construction of torpedoes, the manner of laying and discharging them, the cost, advantages and disadvantages of the different kinds, are fully discussed and are further explained by means of comprehensive drawings. The most efficient method of barricading water would seem to be a combination of ropes and nets and floating torpedoes. Of course, the position of the torpedoes must not be visible from the enemy's ships; only those places which are left free should be marked by buoys for convenience. The conclusion of the volume forms an interesting section on the illumination of the water and banks by fires of wood, calcium, petroleum, and electric lights.

It will thus be seen that Colonel Von Scheliha's work contains much that is interesting and instructive. Indeed, it abounds in information of real practical value to military men. We see how the Confederates discovered new methods of fortifying and defending coasts and rivers, and those methods, although capable of much improvement, have generally sufficed against a superior naval force of the enemy. These methods, and the experience of the four years' war, are well worthy of careful study, and for that purpose no better means offer than Colonel Von Scheliha's treatise. It is but just to add that the publishers have done their best to render the book worthy of the matter. The type, paper, and binding are of the best kind, whilst the large folding plates are beautifully executed, and are perfect specimens of the lithographer's art.

ELECTRICAL MEASUREMENT.*

WHEN we compare the early with the present days of telegraphy, we are truly astonished at the strides we have made with the science. Our knowledge has become greater, and our instruments and observations of greater precision. In no special department has this improvement become more manifest than in that of electrical measurements. When telegraphs were first erected, the instrument used and placed in the hands of inspectors was a simple galvanometer, very similar in construction to the needle and coil of the ordinary needle instrument; when a line broke down the fault was detected by means of this galvanometer, which, from that circumstance, obtained the name of "detector," which still clings to it. In the manufacture of the first submarine cables similar instruments were used, but of far more delicate construction, to note what leakage occurred in the insulator, and whether the copper wire was continuous. As cables improved, instruments of greater delicacy were introduced, as well as more precise methods of observation and record for comparison. We have successively had the introduction of resistance coils, differential galvanometers, Wheatstone's bridge, and Thomson's reflecting galvanometer, which now enable us to take observations with the greatest possible exactitude.

We have been led into the foregoing remarks by the perusal of Mr. Latimer Clark's book on "Electrical Measurement," and it is surprising to note the amount of information and knowledge required now for testing, compared with what it was in those early days we spoke of. The origin of the book is due to the special circumstance of Mr. Clark having designed a modification of the differential galvanometer for use out in India. In sending out those instruments a manual written by him accompanied them, so that the inspector, or whoever had charge of the instrument, might have full information of how to use them, and, at the same time, have the necessary instruction for the various tests which hitherto they had no experience of. Mr. Clark "thought that its publication might be of use to students preparing themselves for the service of the electric telegraph, and to others who might desire an elementary treatise on the subject of electrical measurement." "The first half of the work is designed for the use of the student and the practical telegraphist who has not given much time to the study of his subject;" "the second half is in the form of an appendix, which has been added to make it useful to the practical electrician." Mr. Clark is well known as one of the leading members of his profession, and, as an electrical engineer, his experience of submarine cables and their testing is necessarily large. We are glad to see, therefore, this appendix contain much valuable information, the result of the experience of himself and others, which will be of incalculable advantage to those whose duties are connected with the electrical measurements of submarine cables. It is this part of the work that will be found most useful, as there is an enormous amount of condensed information contained in its pages. We do not praise the second part at the expense of the first: by no means. The chapter on batteries, the methods of measuring their resistances, the explanation of testing by differential and by bridge for faults, as well as for insulation and resistance, will be found most useful to the telegraphist who is anxious to understand the *modus operandi* of electrical measurement.

The first portion contains definitions, mostly illustrated by diagrams, of electrical terms—such as resistance, electromotive force, tension or potential, induction, quantity and units of measurement; it also gives a description of his "double shunt differential galvanometer," and the method of using it for the different purposes of measurement. The usual form of differential galvanometer is a coil wound with two wires of equal length and resistance, so that a current passing through the two wires in opposite directions exactly balances the needle. Mr. Clark's galvanometer differs in detail in minor points, and contains an excellent keyboard for the necessary connections; but the principal "peculiarity of the instrument consists in the addition of a 'shunt' or derived circuit to each half of the galvanometer." These shunts are a multiple of 100, so that the addition of the shunt to one coil enables one hundred times more resistance to be measured. We remember to have used a movable shunt to a differential galvanometer many years ago, so that it could be applied to one coil or the other; but this is the first time, we believe, a double shunt has been attached to a differential galvanometer. With the resistance coils that accompany it, we do not doubt but that it will be found a most useful instrument.

In testing a submarine cable for the measure of its insulation, or, rather, for a method of giving its comparative insulating qualities, a plan has of late come much into use, and it is really about the most satisfactory that can be obtained to give you a perfect knowledge of the insulating capabilities of your dielectric. If an insulated wire be charged with electricity, and then be allowed to remain insulated for a certain interval, it will be found that, according to the insulating properties of the dielectric, a portion of the electricity has escaped. The better the insulator the more charge will be found retained, and *vice versa*; the method usually adopted is to take the time of falling from charge to half-charge. Now, this can be calculated by formula from one observation, instead of frequent observations, until the final correct one is obtained. Mr. Clark gives the following formula for producing the required result; the formula is the same as that given by Mr. Varley to Mr. Hooper for his core:—

$$\frac{\cdot 30103}{log.\ \frac{C}{c}} \times t = n\,t;$$

·30103 being the *log.* of 2 (charge C divided by half-charge); c is charge observed at interval of time t. This formula comes out nearly right with high insulators at low temperatures, but it is quite wrong when applied to gutta-percha at a high temperature. The formula to be correct should prove so under all circumstances, and we therefore venture to submit that it is incorrect. No *rationale* is given for it, neither can we see any. Mr. Clark gives himself the key to the correct formula, when he states that if "a certain" percentage of the charge escape during the first minute, the same percentage of the remaining quantity will escape during the second minute, and so on *ad infinitum*. We have our observation of the percentage of fall in t, interval of time; we require, then, to know how many intervals it will take to fall to half-charge. This is simply a question similar to that of compound interest, and the following formula, supplied by Mr. Preece (see "Culley's Handbook of Telegraphy"), will give the required answer:—

$$\frac{\cdot 30103}{log.\ (1+r)} \times t = n\,t.$$

In this r = percentage of loss in interval of time t; this formula will be found correct with all insulators at all temperatures. In our extract of the above, we have substituted a "certain percentage" for "seven" per cent., which Mr. Clark gives as the escape with gutta-percha at a temperature of 75deg. Fah. Our own observations, as well as those of others, seem to show that this amount is very much understated, and that the escape varies much according to the age and quality

* "An Elementary Treatise on Electrical Measurement, for the Use of Telegraph Inspectors and Operators." By LATIMER CLARK. London: E. and F. Spon, 48, Charing-cross. 1868.

Digitized by Google

of the gutta-percha. We believe that about 25 per cent. will be found about the average.

Our space will not allow us to go into more extended detail, although there are several points we should have wished to have noticed. We may perhaps be able to allude to them in a future number in discussing electrical matter. We believe that the work before us will be received with pleasure by electricians generally, possessing the advantage of combining so much information in so small a space, enabling one to carry on the necessary observations without the reference to the multitudinous works formerly necessary. The author has disarmed us from finding fault with the arrangement of the work, for he remarks that "the book having thus been written in two different portions, is necessarily wanting in all unity of design, for which, as for other imperfections, he claims the indulgence of his readers." The very careful and complete manner in which the work is indexed makes up in a very great measure for this want of unity in design. We trust to see the work run through its first edition, so that, in the next, Mr. Clark may be able to give us a work free from those imperfections to which he, and also ourselves, have alluded, which somewhat mar the utility of a valuable book, such as we must unquestionably acknowledge the present work.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

M. MASSELOTTE'S PROCESS FOR GILDING—GILT WIRE—PASSAGE OF HYDROGEN THROUGH IRON AT A LOW TEMPERATURE—MAGNESIA CYLINDERS FOR THE DRUMMOND LIGHT.

A PROCESS for gilding, the advantages of which, we must confess, we do not exactly see, but which has been deemed worthy of a prize by the Société d'Encouragement, is published in the Bulletin of the society, so we transcribe it for our readers. The articles are first electro-gilded in the ordinary way. An alloy of gold and quicksilver is afterwards deposited from a solution of the cyanides of the two metals. When this coating is sufficiently thick, it is done over with a paste formed of borax, with some additional boracic acid, and sal ammoniac. It is then placed in a fire until the paste is calcined, and afterwards in a bath of acidulated water. By this process a surface of gold is obtained in just the same state as by the old water-gilding process, without any risk to the health of the workmen, and it may be burnished or left dull as desired.

The gilt wire employed in making gold lace soon tarnishes, especially in a London atmosphere. The surface of gold seldom being perfectly continuous, sulphur gets at the metal beneath, whether copper or silver, and the wire quickly blackens. To avoid this result, M. Helouis proposes to insert a thin layer of platinum between the copper and the gold. To do this, he drives a bar of copper into a ring of platinum strongly heated. The contraction of the platinum on cooling fixes it firmly to the copper, and the wire may be drawn without any risk of separating the two metals. The gilding may be done as usual. The colour obtained is as good as that of silver gilt wire, and, of course, lasting, for sulphur will have no effect on the platinum.

Not long ago we gave some account of the transmissibility of gases through cast iron at high temperatures. To-day we give an interesting experiment which shows that hydrogen will pass through cast iron at the ordinary temperature. M. Cailletet took an iron flask with a long (curved) neck, exhausted the air from it, and placed the mouth under mercury. The body of the flask was then set in a vessel of dilute sulphuric acid. The outer surface was, of course, attacked by the acid and hydrogen evolved, some of which passed into the interior of the flask, and, driving out the mercury, escaped in bubbles from the trough. There may be more in this experiment than M. Cailletet suspects. Hydrogen passes into metals with most remarkable facility, and Mr. Graham believes is liquefied within them.

M. Caron has published a short account of the way in which he makes his magnesian cylinders for the Drummond light. He takes magnesia which has been purified from alkalies and the other alkaline earths, and after moistening it with a solution of boracic acid, presses it into moulds. The reason for separating the other alkaline earths and alkalies is that their presence would affect the colour of the light. The boracic acid, we should think, would give a greenish tinge to the flame.

PARLIAMENTARY NOTES.

THE recent melancholy occurrence at Horfield Barracks, near Bristol, gave occasion to Mr. Hayter to ask the Secretary of State for War, on Friday last, whether, having regard to the increased danger to life from the use of breech-loaders in the hands of soldiers either insane or of intemperate habits, he would undertake to advise with His Royal Highness the Field-Marshal Commanding-in-Chief as to the propriety of withdrawing the twenty rounds of ball cartridge now in the possession of all non-commissioned officers and men of the British army, and of serving out the same to the troops on parade when about to proceed on military duty.

Sir J. Pakington said he had not had the opportunity of seeing the Commander-in-Chief that day upon the subject to which the hon. member's question related. Stating merely his individual opinion, he thought the occurrence of a single crime, however atrocious and much to be deplored, would not be cause sufficient for taking a step which would be felt as a slur by the whole army, the ammunition having from time to time been confided to the care of soldiers. We quite agree with Sir John, and believe Mr. Hayter's fears to be groundless.

The great question of the present week has been the Navy Estimates, previously to the discussion of which, however, Captain Mackinnon, a new naval reformer, declined to comply with a request of Mr. Corry, not to let a motion of his stand between committee of supply. The hon. and gallant gentleman then went on to argue out a case, that though our ironclad fleet had cost ten millions, there was scarce a good ship amongst them, and that it was impossible with our vessels to form a line of battle. Mr. Samuda next remonstrated against alleged favouritism in the selection of competitive designs for ships asked from private builders by the Admiralty. Mr. Corry replied to these remarks, after which, the House having gone into committee, commenced the annual statement of the Navy Estimates, at a date nearly three months later than usual. He went into the most minute details, from which we can only spare space for some general points of interest to our readers, reserving our comments for our next number. In the first place, Mr. Corry referred to the increase in the amount over the estimates of last year of £201,937; this, he said, was only an apparent increase, as it included an estimated amount of naval stores, and extra receipts to be paid direct to the Exchequer. In order to institute a fair comparison, that sum must be deducted. The amount of the estimates for 1868-9 is £11,177,290; deduct estimated value of supplies to other departments, £203,292, making the real amount £10,733,998; so that the amount of the two estimates may be said to be practically the same.

Mr. Corry deprecated the further reduction of the estimates by the abolition of our foreign squadron, observing that the value of a foreign squadron was seen when the rebellion broke out in Jamaica, and during the calamities at St. Thomas. Last year the North American and West India squadron consisted of 26 ships and 5,358 men, but it had been reduced to 20 ships and 3,776 men. Notwithstanding the convulsions in South America, our squadron on the south-east coast had been reduced from 9 ships and 1,115 men to 6 ships and 969 men. A reduction had not been practicable on the important Pacific station, where the number of ships was still 12; and the number of men had been increased from 2,676 to 2,755, in consequence of reinforcing the marines on the station. The Australian squadron had been reduced from 5 ships and 1,112 men to 4 ships and 776 men. In the opinion of Sir Henry Keppel and other authorities, the reduction of the China squadron would be attended with danger not only to our commerce, but to the lives of those engaged in carrying it on; and that squadron was of great use in protecting our interests in Japan during the revolution last year. It had been reduced from 36 ships to 34; but the reduction of men was insignificant, being only from 4,082 to 4,080. The only station on which an increase had taken place was the East India station; and the cause was obvious—the Abyssinian war. The squadron had been increased from 7 ships and 1,275 men to 10 ships and 1,815 men; but it would now, no doubt, be possible to revert to the former state of things. He had always regretted the necessity for having a squadron on the West Coast of Africa, and the Admiralty had introduced new regulations, from which the most beneficial results were anticipated. The squadron had been reduced from 18 ships and 1,829 men to 14 ships and 1,475 men.

With respect to Votes 6 and 10, which provided for the building, repairs, equipment of the fleet, and purchase of ships, there was an increase of £117,527, but that increase was owing to the appropriation of large sums for the construction of armour-clads. It was with great reluctance that he made any reduction in the vote for dockyards. He knew that it would throw a number of industrious men out of employment, and that there was also great depression in the shipping trade, and he, therefore, endeavoured to accomplish the reduction with as little inconvenience as possible. At two of the dockyards iron ships were built, and the reduction of men there was only 150; but the reduction at the other yards was 3,049. The number of men now employed was 15,272. In the storekeeper's department there was an increase of £7,106 on timber, and £21,930 for hemp, for which no contract was made last year; an increase of £17,822 on coals, in consequence of the larger use of fuel, especially by the Channel squadron, being a total increase of £31,397.

Turning to our vessels of war, Mr. Corry observed that the ships provided for by the original programme of last year were 4 armour-clads and 37 unarmoured ships, 1 frigate, 2 corvettes, 7 sloops, 26 gunboats, and 1 tug; or a total, armour-clad and unarmoured, of 41 vessels. This was the number in the dockyards. The number ordered by contract when he came into office was 3 armour-clad and 14 unarmoured ships, which he altered to 4 armour-clad and 13 unarmoured. The estimated cost was, for the armour-clads, £915,500; for the unarmoured vessels, £210,800; total, £1,126,300. The estimated expenditure on the two classes in the financial year was £435,150. The total estimate for the ships building by contract was £1,126,300; upon which there had been a total saving of £131,500; and, £79,000 having been spent in building the "Active," ordered in the autumn, there still remained a surplus of £52,900. The number of tons ordered to be built in the dockyards in 1867-8 was 6,854 in armoured ships, and 23,544 in unarmoured ships; and the quantity actually built was 6,829 of the former and 23,256 of the latter—the whole deficiency being 294 tons, notwithstanding several disturbing causes. Three armour-clads—the "Penelope," the "Hercules," and the "Repulse"—were ordered to be launched from the dockyards during the year. Two were launched, and the "Repulse" was ready, but was kept on the stocks for convenience. Twenty-five unarmed ships were ordered to be launched, and were launched, so that the programme had been faithfully performed. The money ordered to be spent on armoured ships by contract was £269,350, and the amount spent was £264,400, or £5,350 less. This punctuality was principally owing to the satisfactory progress made by Messrs. Laird with the "Captain." The sum ordered to be spent on unarmoured ships was £165,800; the amount spent, £119,500, and the deficiency, £46,300. The engagements of the contractors on the whole were well kept.

Following Mr. Corry in his lengthy statement, we find that the number of ships building, or ordered and provided for in this year's estimates is four armour-clads—the "Audacious," the "Captain," the "Invincible," and the "Vanguard"—two corvettes, and one gunboat, and there remain to be delivered during the financial year two armour-clads—the "Repulse" and the "Monarch"—one frigate, two corvettes, five sloops, two gun-vessels, and one tug, being a total ordered and building of twenty-eight vessels, for which £1,162,894 is taken in the present estimates, £759,981 for armour-clads, and £356,913

Digitized by Google

for unarmoured vessels. Mr. Corry stated that, for the present year, there were two unarmoured corvettes, the "Druid" and the "Briton," building in the dockyards. One was being built at Deptford, and would be launched within the present financial year; and he hoped that the whole of the ships now being built at Deptford would be launched within the year. There was no intention to lay down any fresh ships there. In addition to the ships he had mentioned, there were six armoured ships, three of which were to be built in the dockyards, and three by contract. The corvettes would have a tonnage of 1,322 tons, 350-horse power, 12 guns, two of which were 6½-ton guns, and ten 64-pounders; their speed would be thirteen knots, and they would be worked by a single screw.

We now come to the armoured ships, of which there are six. One is being built at Pembroke; the expenditure, says Mr. Corry, would be £70,422, the tonnage was 3,774; an iron-clad with double screw. She would be of 800-horse power, with a speed of 13½ knots, and built on the same principle as the "Audacious" and the "Invincible." Her armament would consist of ten 12½-ton guns, with four 64-pounders on the upper deck. All these vessels would have a large battery on the upper deck, armed with four 12½-ton guns, which would command the whole of the horizon. The next ship, the "Sultan," would be a vessel of the first class, and would resemble the "Hercules." She was to be advanced during the year 2¼-eighths; and her expenditure, £91,113; tonnage, 5,226; single screw, 1,200-horse power, and a speed of nearly fourteen knots. Her armament would consist of eight 18-ton guns on the main deck, and one 12½-ton gun forward, and two 12½-ton guns on the upper deck battery, and two 6½-ton guns under the forecastle. There would be a central armour-plated battery on the upper deck, with two 12½-ton guns, which would range over a large area. The next ship building at Chatham—the "Triumph"—had progressed very little during the year. The estimated expenditure on this ship would be £18,815; she would be an iron-clad broadside sloop, with a single screw lifting. Her tonnage would be 3,800 tons, and her armament would be ten 12½-ton guns, six on the main, and four on the upper deck, and two 64-pounders on the upper deck; her horse power would be 800; estimated speed 12½ knots; and her bottom would be sheathed with wood and copper. These were the three ships it was proposed to commence in the dockyards during the present year. There was another ship to be built by contract, exactly the same as the "Triumph," the estimated cost of which for the present year would be £80,000.

The turret ships next came in for notice, and here Mr. Corry observed that there could be no doubt of the superiority of the turret principle for coast defence, and it was therefore proposed to build a ship, the "Glutton," on that principle. She would be capable of sailing to any port, although it was not intended to make her a cruising vessel. Her cost during the year would be £40,000; her tonnage would be 2,709; length, 245ft.; breadth, 49ft. She would have only one turret, and would fire in all directions. She would have two guns in this turret of 25 tons, if they could be made. She would have 500-horse power, and her estimated speed would be nine knots. The sixth and last ship it is proposed to build is one which in this country will be perfectly new, although there are several such vessels in the French navy. She will be a ram, and capable of accompanying the fleet. It is intended to expend £30,000 upon this vessel during the year. Her length will be 235ft.; breadth, 50ft. She will have a twin screw, and her estimated speed will be twelve knots. She will carry only one 18-ton gun in a fixed tower, with four port-holes; the gun to be worked on a turn-table. Her tonnage will be 2,637; her horse-power, 600.

Turning to the dockyard work we find it is proposed to build of iron-clad broadside frigates, 4,476 tons; of turret ships, 2,072 tons; one iron frigate, 930 tons—making a total of 7,478 tons of armoured shipping. Of unarmoured shipping, one frigate 1,680 tons; wooden corvettes, 1,607; iron corvettes, 120; sloops, 1,623; twin-screw gun vessels, 1,241; small twin-screw gunboats of second class, 240; tug steamer, 20; and mooring lighters, 400—making a total of 6,931 tons in unarmoured ships. With respect to the actual state of the armour clad navy, including ships ordered to be built, under these estimates, of the first and second class there are in commission, fitting for reserve, and building, thirty-four. The estimates provide also for a great want, namely, a reserve of iron-clad ships of war in our dockyards in such a state of preparation as to meet any emergency, and by October 1 Mr. Corry expects to have the "Black Prince," the "Agincourt," the "Northumberland," the "Sovereign," the "Hector," the "Resistance," and the "Hercules."

To sum up matters, we find that the nominal estimate for the year is £11,177,290, the actual one £10,826,690; the nominal increase over last year £201,037, but the real increase only about £9,000. The number of men, including marines, is 67,120 this year, as against 69,762 last year, and there has been a reduction of fifteen ships and 2,768 men in the squadrons on foreign service, while generally there have been reduced 1,333 seamen proper and 1,500 marines. We have now forty-four iron-clad ships, of which eleven are building. Some of these will be launched this year, and eighteen new vessels of various kinds will in that period be added to our navy. There will be a reserve of seven powerful armoured ships. The general condition of the navy, as regards health, efficiency, and discipline is exceedingly satisfactory.

After some discussion, in which Mr. Childers took a very active part, the vote was agreed to, and the Admiralty authorities are now supplied with the sinews of war for another year and once more made happy. Let them look to the use they make of them.

MR. WHITWORTH'S SCHOLARSHIPS.

THE practical and praiseworthy step taken by Mr. Whitworth in furtherance of the object of technical education has met with the consentaneous approval of all, as, indeed, it could not fail to do. We have now before us copies of documents relating to the details of this noble endowment, which applies to all subjects of the Queen, whether at home or abroad. We, therefore, place the matter before our readers without comment, which is superfluous, but with the hope that others who have the ability may have also the will to imitate so excellent an example.

"I. Minute.

"At Whitehall, the 5th day of May, 1868.

"By the Right Hon. the Lords of the Committee of Her Majesty's Most Hon. Privy Council on Education.

"My Lords read Mr. Whitworth's letter of the 4th of May, 1868, transmitting a memorandum on his scholarships, and on the establishment of 60 exhibitions of £25 for the present year preparatory to the competition for his scholarships, and requesting that the Science and Art Department may conduct the necessary examinations and correspondence.

"Their Lordships have great pleasure in acceding to Mr. Whitworth's request, and giving every assistance in their power in carrying out his patriotic munificence."

"II. Mr. Whitworth's Letter.

"Manchester, May 4.

"Sir,—Referring to your letter of March 28, by which you transmit to me a copy of the minute which the Lords of the Committee of Council on Education had passed in acknowledgment of my endowment of scholarships for promoting mechanical science, and to the concluding sentence of the minute, which invites further suggestions, and offers to render assistance in carrying out the intentions of the endowment:—

"1. I beg leave to enclose, for the information of the Lords of the Committee of Council on Education, a memorandum on the subject of the endowment, which I trust will meet with the approval of their Lordships, and that they will cause it to be circulated, and the necessary correspondence arising out of it to be conducted by the Science and Art Department.

"2. I would beg leave to ask the Lords of the Committee of Council on Education to undertake the examinations for these scholarships.

"3. As respects the preparation of the necessary details, for the examinations in the use of tools, I am willing to be responsible myself, with the aid of friends; and I propose to obtain the consent of a few gentlemen to advise with me from time to time in whatever may arise in the future for my consideration.

"4. In reply to the invitation of their Lordships to submit any suggestions, I venture to submit for consideration whether honours in the nature of degrees might not be conferred by some competent authority on successful students each year, thus creating a faculty of industry analogous to the existing faculties of divinity, law, and medicine. I am of opinion that such honours would be a great incentive to exertion, and would tend greatly to promote the object in view.

"5. I venture further to express a hope that the Government will provide the necessary funds for endowing a sufficient number of professors of mechanics throughout the United Kingdom.

"6. In conclusion, I inform you that the necessary arrangements for securing the endowment have been made, and I have given instructions for the preparation of the draught of a deed of trust which will be sent for the approval of the Lord President.

"I am, Sir, your obedient servant,

"Joseph Whitworth.

"To Henry Cole, Esq., Secretary of the Science and Art Department."

"III. Memorandum on Scholarships of £100 for Mechanical Science and Practice.

"To be competed for in May, 1869.

"I. Having offered to the Lords of the Committee of Council on Education to 'found 30 scholarships of the annual value of £100 each, to be applied for the further instruction of young men, natives of the United Kingdom, selected by open competition for their intelligence and proficiency in the theory and practice of mechanics and its cognate sciences, with a view to the promotion of engineering and mechanical industry in this country,' I propose that the following should be the general arrangements in the first instance, which may be modified after the first competition has taken place in May, 1869.

"II. That the 30 scholarships of £100 each should be open to all of Her Majesty's subjects, whether of the United Kingdom, India, or the colonies, who do not exceed the age of twenty-six years, and be held either for two or three years, as experience may prove to be desirable: that ten scholarships should be competed for and awarded in May, 1869, at the annual national examinations in science, provided that a sufficient number of candidates prove themselves to be competent; that the successful candidates should be required to spend the period of holding the scholarships in the further satisfactory prosecution of the studies and practice of mechanical engineering, and pursue their studies according to the spirit of the endowment, making periodical reports of them; that the student should state where he proposes to pursue his studies, the Lord President of the Council deciding if the proposal can be allowed, also if the student's progress be satisfactory, and the manner in which it shall be tested from year to year. In deciding if the plan of study proposed by the student be satisfactory, as much latitude as possible may be allowed. If the student wish to complete his general education instead of continuing his special scientific study, he may be permitted to do so. He may go to the universities or colleges affording scientific or technical instruction, or he may travel abroad. The successful artizan should be encouraged to study theory, and the successful competitor in theory aided in getting admission to machine shops and other practical establishments. All further details would be hereafter prepared and issued by the Science and Art Department.

"III. The candidates must be of sound bodily constitution.

"IV. The first competition should be in the following theoretical subjects:—1. Mathematics (elementary and higher). 2. Mechanics (theoretical and applied). 3. Practical plane and descriptive geometry, and mechanical and freehand drawing. 4. Physics. 5. Chemistry, including metallurgy. And in the following handicrafts:—1. Smiths' work. 2. Turning. 3. Filing and fitting. 4. Pattern making and moulding.

"V. No candidate should obtain a scholarship who has not shown a satisfactory knowledge of all the following theoretical subjects:—1. Elementary mathematics. 2. Elementary mechanics. 3. Practical plane and descriptive geometry and freehand drawing. With the power to use one or more of the following classes of tools:—*a*, the axe; *b*, the saw and plane; *c*, the hammer and chisel; *d*, the file; *e*, the forge. I propose that the maximum number of marks obtainable in the theoretical subjects and those obtainable by the most skilled workman should be about equal.

"VI. My object in devising the foregoing scheme has been, while requiring a practical aquaintance with a few simple tools as a *sine qua non*, to render the competition accessible on fairly equal terms to the student who combines some practice with his theory, and to the artizan who combines some theoretical knowledge with perfection of workmanship.

"Preparatory Exhibitions of £25 for the Year 1868.

"VII. As the scholarship scheme can only come

Digitized by Google

into full operation by degrees, I propose from the fund ultimately available for the scheme at once to create 60 exhibitions or premiums, of the value of £25 each, tenable until April, 1869, and to place them at the absolute disposal of the governing bodies of the following educational institutions and towns, in order that they may award them to youths under 22 years of age, who may thus be aided to qualify themselves, and must undertake to compete for the scholarships of £100 in May, 1869,

"VIII. Eight exhibitions to Owen College, and two to the Grammar School, Manchester, the seat of my workshops; three University of Oxford; three University of Cambridge; three University of London; and one to each of the following Universities, Colleges, and Public Schools:—University of Durham, University of Dublin, University of Edinburgh, Watt Institution, Edinburgh; University of Glasgow, Andersonian University, Glasgow; University of St. Andrew's, University of Aberdeen, to each of the Queen's Colleges at Belfast, Cork, Galway, Ireland; King's College, London; University College, London; Eton, Harrow, Rugby, Charterhouse, Westminster, Winchester, St. Paul's, London; Merchant Taylors, Christ's Hospital, City of London, Shrewsbury, Marlborough, Cheltenham, Chester, Clifton, Brighton, Liverpool, two to the College of Preceptors, three to the Science and Art Department. I propose that the following exhibitions shall be given to artizans only:—Three to the Society of Arts; also one for artizans to each of the following towns:—Birmingham, Bristol, Swansea and Cardiff, Halifax or Huddersfield, Leeds, Northampton, Sheffield, and if there be any of the above unapplied, they may be given by the Science and Art Department to any other scholastic institution which makes satisfactory arrangements for affording instruction in mathematics and mechanics, freehand and mechanical drawing.

"IX. I would point out that the exhibitions to artizans may, perhaps, be increased to £50 for the year, by connecting them with the Science and Art Department, under the minute of the 21st December, 1867.

"Manchester, May 4. JOSEPH WHITWORTH."

MICROSCOPICAL EXAMINATION OF THE SOLID PARTICLES FROM THE AIR OF MANCHESTER.

BY J. B. DANCER, F.R.A.S.

WE recently noticed a paper read by Dr. R. Angus Smith, before the Literary and Philosophical Society upon the search for solid bodies in the atmosphere. That paper will be appropriately supplemented by the following one, from Mr. Dancer, on the microscopical examination of the solid particles found in the 2,495 litres named in Dr. Smith's paper, and the amount of fungoid matter in which is rather surprising. The air had been washed in distilled water, and the solid matter which subsided was collected in a small stoppered bottle, and on the 13th of March Dr. Smith requested me to examine the matter contained in this water. An illness prevented me from giving it so much attention as I could have wished. The water containing this air-washing was first examined with a power of 50 diameters only, for the purpose of getting a general knowledge of its contents; afterwards magnifying powers varying from 120 to 1,600 diameters were employed. During the first observations, few living organisms were noticed; but, as it afterwards proved, the germs of plant and animal life (probably in a dormant condition) were present.

I will now endeavour to describe the objects found in this matter, and begin in the order in which they appeared most abundant. First, Fungoid matter.—Spores or sporidiæ appeared in numbers, and, to ascertain as nearly as possible the numerical proportion of these minute bodies in a single drop of the fluid, the contents of the bottle were well shaken, and then one drop was taken up with a pipette; this was spread out by compression to a circle half an inch in diameter. A magnifying power was then employed, which gave a field of view of an area exactly 100th of an inch in diameter, and it was found that more than 100 spores were contained in this space; consequently, the average number of spores in a single drop would be 250,000. These spores varied from 10,000th to 50,000th of an inch in diameter. The peculiar molecular motion in the spores was observable for a short time, until they settled on to the bottom of the glass plate; they then became motionless. The Mycelium of these minute fungi were similar to that of rust or mildew (as it is commonly named), such as is found on straw or decaying vegetation.

When the bottle had remained for thirty-six hours in a room at a temperature of 60deg. the quantity of fungi had visibly increased and the delicate mycelial thread-like roots had completely entangled the fibrous objects contained in the bottle and formed them into a mass. On the third day a number of ciliated zoospores were observed moving freely amongst the sporidiæ. I could not detect any great variety of fungi in the contents of the bottle, but I cannot presume to say that all the visible spores belonged to one species, and as there are more than 2,000 different kinds of fungi it is possible that spores of other species might be present, but not under conditions favourable for their development. Some very pretty chain-like threads of conidia were visible in some of the examinations.

The next in quantity is vegetable tissue. Some of this formed a very interesting object, with a high power, and the greater portion exhibited what is called pitted structure. The larger particles of this had evidently been partially burnt and quite brown in colour, and were from coniferous plants, showing with great distinctness the broad marginal bands surrounding the pits; others had reticulations small in diameter. They reminded me of perforated particles so abundant in some kinds of coals. The brown or charred objects were probably particles of partially burnt wood used in lighting fires. Along with these reticulated objects were fragments of vegetation, resembling in structure hay and straw and hay seeds, and some extremely thin and transparent tissue showing no structure. These were doubtless some portions of weather-worn vegetation. A few hairs of leaves of plants and fibres, similar in appearance to flax, were seen, and, as might have been expected in this city, cotton filaments, some white, others coloured, were numerous, red and blue being the predominant colours. A few granules of starch, seen by the aid of the polariscope, and several long elliptical bodies, similar to the pollen of the lily, were noticed. After this dust from the atmosphere had been kept quiet for three or four days, animalcules made their appearance in considerable numbers, the monads being the most numerous. Amongst these were noticed some comparatively large specimens of paramecium aurelia, in company with some very active rotiferæ; but after a few days the animal life rapidly decreased, and in twelve days no animalculæ could be detected.

Very few hairs of animals were noticed, with the exception of wool; of this both white and coloured specimens were mixed up along with the filaments of cotton. After each examination as much of the drop of water as could be collected by the pipette was returned to the bottle, in order to ascertain if any new development of animal or vegetable life would take place, and the stopper of the bottle was replaced as quickly as possible to prevent the admission of the particles from the air in the room; and I am tolerably certain that the objects named in this paper are those which the bottle contained when Dr. Smith brought it to me. The particles floating in the atmosphere will differ in character according to the season of the year, the direction of the wind, and the locality in which they are collected, and, as might be expected, are much less in quantity after rain.

The small amount of fluid now remaining in the bottle emits the peculiar odour of mildew, and at present the fungoid matter appears inactive. For the purpose of obtaining a rough approximation of the number of spores, or germs of organic matter contained in the fluid received from Dr. Smith, I measured a quantity by the pipette, and found it contained 150 drops of the size used in each examination. Now, I have previously stated that in each drop there were about 250,000 of these spores, and as there were 150 drops, the sum total reaches the startling number of 37½ millions, and these exclusive of other substances, were collected from 2·495 litres of the air of the city*—a quantity which would be respired in about ten hours by a man of ordinary size when actively employed. I have to add that there was a marked absence of particles of carbon amongst the collected matter.

LORD COLCHESTER and the Right Hon. Stephen Cave, M.P., have been placed on the Commission to enquire into the condition of the Exchequer standards of weights and measures, in the room of the Earl of Rosse and Lord Wrottesley, deceased.

* Behind Dr. R. Angus Smith's laboratory.

ROYAL INSTITUTION.

ON the evening of Friday week, Mr. F. T. Palgrave gave a lecture at the Royal Institution on the subject of the formation of good taste in art. Mr. Palgrave's argument was that independently of the individual partiality of every observer for particular works of art, there is such a thing as good taste, governed by fixed laws, and dependent upon accurate knowledge. Among the things which ordinary observers and inferior artists often overlook were "the laws of material." In sculpture, for instance, he said that marble is only suited for works of repose, whilst bronze, being a lighter material, and of more tenacity, is suitable for works of activity. As the lecture closed considerably before the usual time, Professor Tyndall was invited to state what he saw during his recent visit to Vesuvius, and he stated that he had just returned from Naples, where Sir John Lubbock and himself had been examining the phenomena of the eruptions The country all round Naples is very smoking and hot, showing the existence of extensive subterranean fires, but they had gained no information of scientific value. On different occasions they ascended the mountain from different sides, and in one instance, when a hurricane of wind favoured them, they went further than the guide would lead them, and had a look down the fiery tube of the crater itself. The wind was so strong, that on the way Sir John Lubbock was blown down flat on his face. They also explored some hot subterranean galleries in the side of the mountain, and visited the Grotto del Cano, the well-known cavern, where the floor is covered several feet deep with carbonic acid gas. The heavy invisible gas, in fact, runs out of the cavern in a great stream, and will in the open air put out torches when they are held near the ground. He repeated some of the commoner experiments with the carbonic acid gas, by collecting some in his hat, and carrying it away a little distance from the cave, where it was poured over lighted matches, and put out the flame. A little dog is kept near the cave to be half suffocated, by immersion in the gas when visitors arrive; and Professor Tyndall protested against the cruelty of the experiment, which, he says, serves no useful purpose, and ought to be stopped.

THE NATIONAL RIFLE ASSOCIATION.

THE Council of the National Rifle Association have submitted to His Royal Highness the Field-Marshal Commanding-in-Chief the proposal to offer the following series of prizes, to be competed for at Wimbledon by non-commissioned officers and privates of Her Majesty's regular army. His Royal Highness has approved of the programme, and the Secretary of State for War has kindly complied with the request of the Council that the competitors from the various regiments should be provided with routes to proceed to Wimbledon. The "Army" Prizes and Challenge Cup, total aggregate value £265, presented by the National Rifle Association, to be competed for by non-commissioned officers and privates, being marksmen in Her Majesty's regular forces, two competitors from each regiment or battalion. First stage:—£155, divided into 50 prizes, as follows:—One prize of £10, four prizes of £5, ten prizes of £4, fifteen prizes of £3; twenty prizes of £2. Distances, 500yds. and 600yds.; number of shots, five at each distance; rifles, regulation three-groove Snider; ammunition, Government; position, regulation; sighting shots, two gratis at each distance. The prizes will be adjudged according to the highest aggregate scores made at the two distances. Second stage.—A cup, value £100, and a prize of £10 to the best shot. Competition restricted to the winners of prizes in the first stage. Distance, 600yds.; number of shots, seven; rifles, ammunition, position, sighting shots, as in first stage. The cup shall be held by the officers of the regiment, if at home; and, if abroad, by those of the depôt battalion to which the regiment is attached. In each case the commanding officer shall be responsible for the safe custody of the cup, and for its return to the Secretary of the National Rifle Association by June 20 of the year following that in which it was competed for. The Spring General Meeting of the National Rifle Association will be held at Willis's Rooms on Thursday, May 21, at 2·30 p.m., Field-Marshal his Royal Highness the Duke of Cambridge, President, in the chair.

DURING the past week thirty-six wrecks were reported, making for the present year 855.

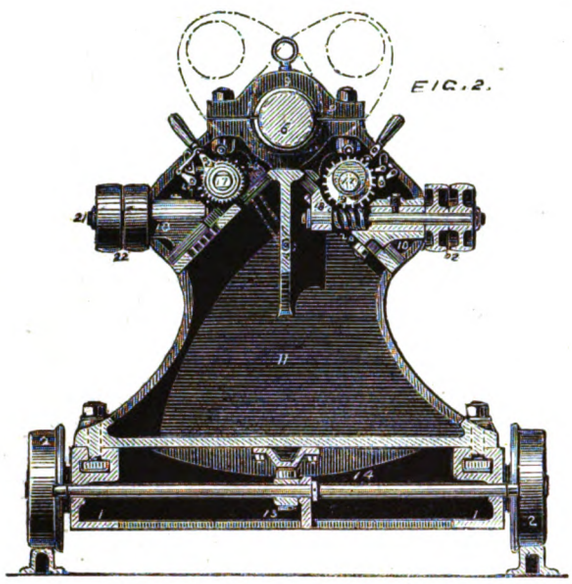
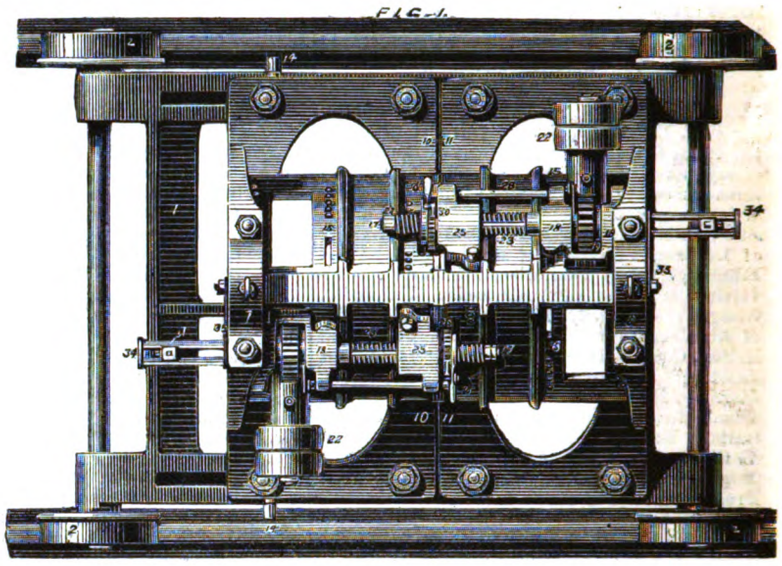
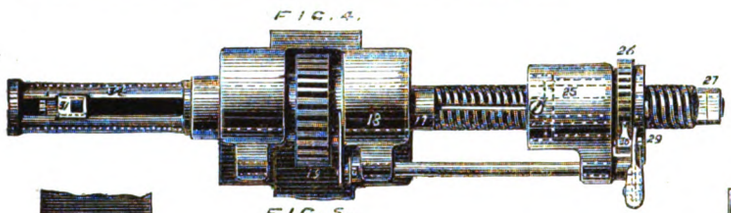
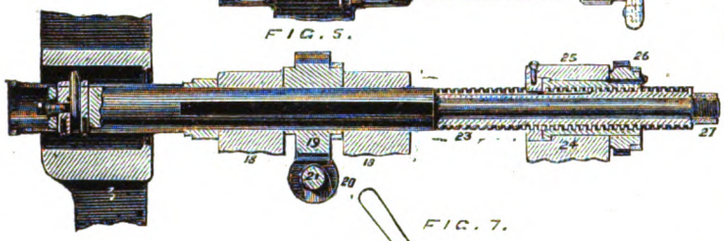
APPARATUS FOR FINISHING PARTS OF LOCOMOTIVE WHEELS.

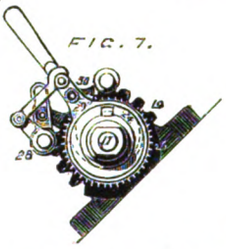
BY MR. JAMES REID.

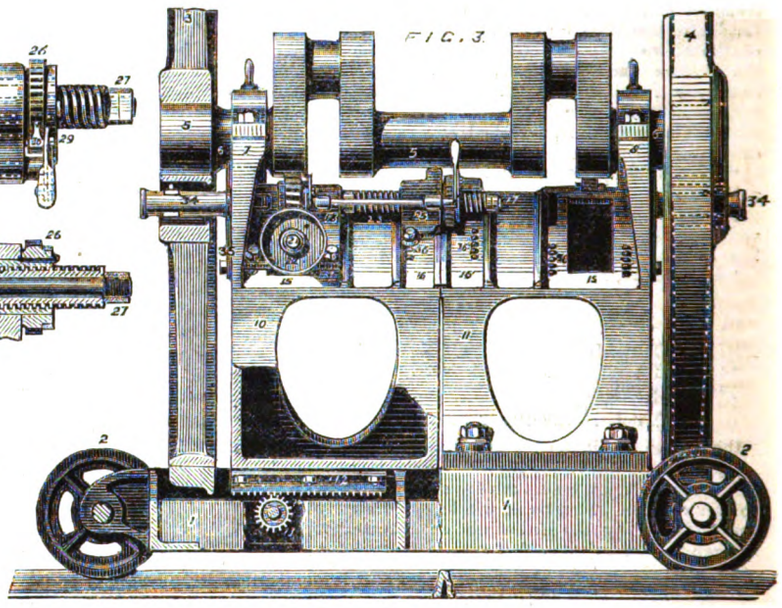












APPARATUS FOR FINISHING PARTS OF LOCOMOTIVE WHEELS.

MR. JAMES REID, of the firm of Messrs. Neilson and Co., Hyde-park Locomotive Works, Glasgow, has recently patented an apparatus for finishing the details of locomotive wheels. It was designed by him, and constructed especially for the above establishment, where it is at work and giving the most satisfactory results. It overcomes the practical difficulties experienced in all other machines, and is all that can be desired. The apparatus refers, principally, to the crank pin holes, and comprises arrangements for accurately adjusting a pair of wheels by means of the journals of their axle for insuring the crank pin holes being accurately in planes at right angles to each other, and parallel to the journal axis, and for forming these holes with a uniform and correct taper. The improved details for forming the taper are also applicable to the axle holes. In our engravings, fig. 1 is a plan; fig. 2 is a transverse vertical section; and fig. 3 is a sectional side elevation of the apparatus. Figs. 4, 5, 6, and 7, are enlarged views of one of the tool spindles and its accompanying details.

The apparatus is represented as mounted on a truck frame 1 with wheels 2, but it can be fixed to a stationary foundation. Mr. Reid, however, prefers to arrange it as shown, so that it can be run under any convenient crane to receive a pair of wheels to be operated upon, and to be thence transferred to any locality where a pair of driving belts can be conveniently applied to it. The pair of wheels 3 4 having been previously placed and keyed on their axle 5, this is placed horizontally in the machine with the journals 6 in bearings 7 8, provided for them, and furnished with accurately-formed lining pieces 9 (fig. 2) adapted for different diameters of journal. The bearings 7 8 are also adjustable at different distances apart, to obtain which adjustment, the body of the machine is made in two separate castings 10 11, and one (10) has a rack 12 fixed to its under side, having in gear with it a pinion 13 on a shaft 14 carried in the truck frame 1, and formed with squared ends to receive keys or handles. Elongated holes are provided in the truck frame 1 for the bolts, by which the adjustable body part 10 is fixed to it, and these bolts are loosened when a change is required in the adjustment.

The provision for adjusting the bearings 7 8 more or less apart is convenient for a private establishment for constructing locomotives where various gauges have to be provided for; but when only one gauge has to be provided for, as at the works of a railway company, the body of the machine may be made in a single casting. For such works also it may be convenient to have the machine permanently fixed to a stationary foundation. Between the bearings 7 8 the body or framing 10 11 is formed with equally inclined surfaces or seats 15 16 on opposite sides of the longitudinal centre line, and the surfaces 15 16 on one side are made accurately at right angles to the corresponding surfaces 15 16 on the other side. On these inclined seats a series of racket castings or heads are fixed for carrying the boring bars or tool spindles with their driving and feeding gear. There are two boring bars which are set at diagonally opposite corners, but, for the sake of clearness, we will describe the details connected with one only, those of the other being exactly alike. The boring bar 17 is carried in two bearing heads formed on one casting 18, and has on it between these heads a worm wheel 19 which turns it by means of a key and groove, and which is driven by a worm 20 on a shaft 21 carried in bearings in the same casting 18. The shaft 21 is provided with fast and loose pulleys 22 to receive a driving bel from any convenient shaft. The back end of the boring bar 17, which end is of reduced diameter, has on it a tube 23 screwed externally to work in an internally screwed bush 24, which is held in a bearing head 25, and which has a spur feed wheel 26 keyed on its projecting back end. The screwed tube 23 is prevented from turning by means of a groove and key, and it is held on the boring bar 17 so as to make this bar move longitudinally with it by nuts 27 screwed on the outer end of the bar.

The feeding is effected by means of an eccentric formed on the side of the worm wheel 19, the strap of which eccentric actuates a rocking spindle 28. A lever and link at the other end of tthe rocking spindle 28 imparts a reciprocating motion o an armed ring 29 loose on a flange on the feed spur wheel 26 on which the armed ring acts by m ans of a reversible catch 30. The front end of the boring bar 17 is formed with a transverse slot, and in this a small block 31, which is the tool holder, has the small transverse movement necessary for producing the taper of the crank pin hole 32. The steel tool or cutter 33 fits in a square socket in the holder 31, and is fixed by a pinching screw. The holder 31 is formed with flanges at one end, and a flange piece is fixed upon the other end after the holder is put into its slot. These flanges bear on the outside of a tube 34 fitted on the boring bar 17, so that this bar can move longitudinally in it. The tube is formed with longitudinal slots in which the ends of the holder move as the bar is fed along; and the outside of the tube is turned concentric with an axis slightly inclined to the axis of its bore in a plane passing through the centre lines of the slots, which causes the edges at the slots that the holder flanges bear on to be slightly tapered or inclined. With this arrangement, as the tube 34 is stationary from bearing against the casting 18, the longitudinal move-

Digitized by Google

ment inwards of the boring bar 17 causes the slight transverse movement of the tool that produces the required taper. The tube 34 is kept against the casting by a lever collar clutch 35, which prevents it from moving outwards with the boring bar. The castings 18 and 25, which carry the boring bar and its accessories, can be shifted in such a way that the two tools can be placed at either diagonal pair of corners of the body or frame to suit either a pair of wheels with the right-hand crank pin leading, or a pair with the left-hand one leading.

When effecting a change from one diagonal disposition to the other the various parts are separated, the boring bar 17 and the screwed tube 23 are entered into their places the opposite way, and the castings 18 and 25 are respectively fixed on the seats 15 and 16, represented in the engraving as unoccupied. If the parts are shifted to the opposite ends of the same sides the larger casting 18 has not to be turned about, but the smaller one 25 has to be so turned. Duplicate lugs for carrying the rocking spindle 28 are required and provided, and the worm wheel 19 is formed with eccentries on both sides of it, so that it can be put into its place either way. Provision is made for different throws of effective lengths of crank by having gauge holes 36 corresponding to the various throws ordinarily adopted accurately bored in the inclined body surfaces or seats 15 16 to receive pins fixed in the under sides of the brackets or castings 18 25, or screw bolts, by means of which these castings are fixed to the seats, the holes and pins or bolts being carefully bored and turned to fit each other accurately. The surfaces of the seats 15 16 are parallel to planes at right angles to each other, and passing through the centre line or axis of the journal bearings 7 8, and the boring bar bearings in the castings 18 25 are actually constructed so that their centre lines are in the said planes in all positions of those castings.

THE MIDLAND RAILWAY TERMINUS.*

By PROFESSOR DONALDSON.

I VENTURE to call the attention of the members to the terminus of the Midland Railway, near King's-cross, London, which may be considered one of the most important works now carrying on in our metropolis, vast in extent—for it will cover seven acres—and gigantic in the proportions of its terminus shed. This grand feature is distinguished by a construction which, as to boldness and ingenuity, reflects the highest credit for conception and execution, on its eminent engineer, Mr. W. H. Barlow; on Messrs Waring the contractors; on Messrs Ordish and Le Fouvre, who designed the details of the roof; and on Mr. Alleyne, of the Butterley Iron Works, who arranged the travelling, staging, and hoisting gear for the purpose of fixing the roofing in its place.

The roof of the terminus shed is 690ft. long and has a clear span of 240ft. The main ribs, which are 29ft. 4in. apart from centre to centre, are latticed, and 9ft. deep, forming the curve of four-centred pointed arch, the radii being 57ft. and 160ft. respectively, and rising to the height of 96ft. above the level of the platform. The feet of the ribs cover a remarkably small area, as though they stood on pins; but here at the springing, instead of being latticed, they have plate webs and are let into a shoe, which spreads out on each side and to the projection of a buttress, so as to give a firm footing, and these shoes are bolted down to anchor plates at the foundation, built into the wall to ensure further stability. Except the shoes, the whole consists of plate iron, three intermediate ribs between the main ribs being of rolled iron, I-section, 10½in. deep. There are at regular distances on the sweep of the roof trussed purlins to carry the intermediate ribs, and so constructed that they stiffen laterally the lower flanges of the main ribs. In the whole height of the roof there are no ties, the sweep being so adjusted, and the weight so distributed and equipoised, that the series of girders, about 2ft. deep, extending across the station at the level of the floor, are sufficient to retain the feet and resist the tensile strain at that point upon the ribs.

The floor is also designed with considerable ingenuity, and merits our attention. The whole area, 690ft. by 240ft., is upheld by a series of cast columns, 14ft. 8in. apart from centre to centre, and 15ft. high, and on the caps are the transverse girders already mentioned and a series of longitudinal girders. The vaulting, if it may be so called, of this basement storey or ceiling rests on this network of girders, and is formed of Mallet's buckled plates securely fixed to the girders, and thereon comes the floor. Thus it will be perceived that the columns afford clearer space for stowage beneath than piers would have done, and the buckled plates are lighter and more sure in construction than brick vaults.

The ribs and roofing are erected and fixed in place by means of a travelling staging and hoisting gear. The system on which Mr. J. G. N. Alleyne, of the Butterley Iron Works, has designed the staging is, that the main rib is never lost hold of until all the wind-ties are finally fixed to the walls. The staging is divided into three sections, the centre consisting of six divisions, the side ones of five divisions each, and from front to rear there are four divisions. The standards consist of die-square balks of timber, 12in. square; the horizontal traverse pieces are double, 12in. by 6in. each, except the two lower one, which is 12in. square, with iron shoes bolted down to receive the feet of the standards and braces. The cross braces are 12in. by 12in. in the lower tiers, 10in. by 10in. in the two next tiers, and in the upper ranges 9in. by 9in. The wheels, on which the three sections move, are 2ft. 8in. in diameter, and run on a balk of timber 18in. square; altogether, there are 123 wheels under the staging. Of course, the three divisions of the staging can be moved, and are moved distinctly and separately; but when main ribs are being hoisted and adjusted, they are all three bolted together at each horizontal timber with wrought-iron clamps and bolts, and screwed firmly together against a chock of timber. Each gallery of the stage is fitted with two slides, which are forced outwards against the rib by folding wedges, so that the work can be adjusted to the greatest accuracy.

For moving the staging the following process is followed. When, in the first instance, two ribs have been fixed and the riveting finished, and everything is properly adjusted, the folding wedges of the two side stages are knocked out; the rib, in taking its proper deflection, rests firmly on the centre compartment; the wedges of this are not disturbed, the whole centre compartment being kept bolted down to the floor. The slides are drawn inwards, and the side divisions of the staging are moved, so that the slides orginally opposite to No. 1 rib are brought to be opposite No. 2. rib; they are then wedged out and hold No. 2, and are in turn bolted down to the floor. The wedges of the centre compartment are now removed; it is set free from the floor, moved up to No. 2 rib, and the three compartments or divisions are bolted together as before, and are then ready for No. 3 rib. The sides may be moved in about thirty minutes each, and the centre in ten minutes. These movements may be effected by hand-power of three men with iron bars to each wheel. For hoisting steam-power is used. The derrick employed for the purpose is arranged with an universal joint, so that it can be raised, lowered, or twisted round in any direction. The steam crab is furnished with a double warping barrel, so that the rope does not accumulate on it—a system first used, probably, at the Exhibition in London, 1862.

* Read before the Royal Institute of British Architects.

VENTILATION OF BARRACKS.

A PAPER, of which the following is an abstract, was recently read before the Society of Arts on a new ventilating stove in use for barracks and military buildings, by Mr. Douglas Galton, C.B., F.R.S. The stove was designed about eight years since to meet the conditions laid down by the Barrack and Hospital Improvement Committee at that period, and which aimed at supplying at all seasons every room in a building, by itself, and independent of the other rooms, with a sufficiency of air, and at the same time to prevent the temperature from falling below a desirable point. The committee, not being satisfied with the form of grate already in use, adopted the fireplace which this paper is intended to describe. The stove, which is not patented, is made of the best cast iron, and consists of three pieces, connected by screws. The first piece forms the moulded projecting frame, the second the body of the grate, and the third the nozzle or connection with the smoke-flue, the bottom flange of which is bolted to the back of the grate. The stoves are made in three sizes. The fireplace has a lining of clumps in five pieces—two sides, one back piece, and two bottom pieces. A clear space half an inch deep is formed between the back lump and the iron back to receive a supply of air through the ash-pit, which passes through a slit in the fire lump immediately above the fire. By this means a more perfect combustion of the smoke is effected. The flame, heated gases from combustion, and small amount of smoke as exists are compelled to impinge upon a large heating surface, so as to subtract as much heat as possible out of them before they pass into the chimney, and the heat thus extracted is employed to warm air taken directly from the outer air. The fresh air when warmed is passed into the room by a flue near the ceiling. The flue, which has been adopted for barracks, is carried up by the side of the smoke flue in the chimney breast. The grate (No. 1 size) will contain about 18lb. or 20lb. of coals; 40lb. will maintain a good fire for 16 hours, that is, at the rate of about 2.5lb. per hour.

In new buildings it would be very desirable to carry up the smoke flue inside the warm air flue, and so extend the heating surface. This plan was adopted in the wards of the Herbert Military Hospital, where the fireplace is in the centre of the ward, and the chimney consequently passes under the floor, and by this means an additional heating surface of 36 square feet has been obtained. The limit to which the heat from the fire can be so utilized is the point at which it cools down the chimney so as to check the draught and combustion of the fuel. With respect to the application of the grate to existing buildings, the recess in which an ordinary fire grate would be fixed forms the chamber in which the air is warmed. The front of the stove can be easily removed, thus rendering the air-chamber accessible for cleansing purposes. In applying the stove to existing fireplaces the air-chamber must be left as large as possible, cleansed from soot, and lime whited. Should the fireplace be deeper than 1ft. 6in., the depth required for the curved iron smoke flue, a lining of brickwork is built up at the back to reduce it to that dimension. The chimney bars, if too high, must be lowered to suit the height of the stove, or to a height of 3ft. 3in. above the hearth. They must also be straightened to receive the covering of the air-chambers. These coverings should be of 3-inch York or other flagging, cut out to receive the iron smoke flue, and also to form the bottom of the warm air flue in the chimney breast. In new buildings the air-chambers may be rectangular. They must be 4in. narrower than the extreme dimensions of the moulded frame of the stove, so as to give a margin of 2in. in width all round for a bedding of hair mortar.

General results of numerous experiments show that the air is admitted to the rooms at a temperature of from 20deg. to 30deg. Fah. above that of the outer air. The design of the grate was intended to preclude the possibility of such a temperature as would in any way injure the air introduced. The principle of these arrangements has been adopted for barracks in the case of grates for married soldiers; these would be useful as cottage grates. These grates have a small oven, and an open fire; warmed air is introduced into the room by means of an iron flue, carried up from the fire-brick lining of the stove inside the chimney, and introduced into the room near the ceiling through a louvred opening; by this means the heat of the smoke is utilized. This description of grate was devised for the purpose of combining a power of cooking for a cottage with great compulsory economy of fuel. It must, however, always be observed that in proportion as the heat is removed from the chimney, so is the draught, *i.e.*, the effect of the chimney as a pumping engine to remove the air, diminished, and the combustion of the fuel to some extent checked. There is one point connected with the flue which must be carefully attended to, viz., the fresh air should be taken from places where impurities cannot affect it, and the flue must be so arranged and constructed as to afford easy means of being periodically thoroughly examined and cleaned. In barracks the rule is that such cleansing should take place at least once a year. Now that the question of economy of fuel is becoming daily of more importance, it is desirable that we should adopt every means of utilizing, to the fullest practical extent, the fuel which we burn. If this was done in all households the saving of fuel to the country and of money to individuals would be considerable.

In conclusion, the merits which are claimed for this fireplace are:—

1. That it ventilates the room.
2. That it maintains an equable temperature in all parts of the room, and prevents all draughts.
3. That the heat from radiation is thrown into the room better than from other grates.
4. That the fire-brick lining prevents the fire from going out, even when left untouched for a long time, and prevents the rapid changes of temperature which occur in rooms in cold weather from that cause.
5. That it economises fuel partly by making use of the spare heat, which otherwise would all pass up the chimney, and partly by ensuring by its construction a more complete combustion, and thereby diminishing smoke.

THE GOVERNMENT BREECH-LOADING REVOLVER.

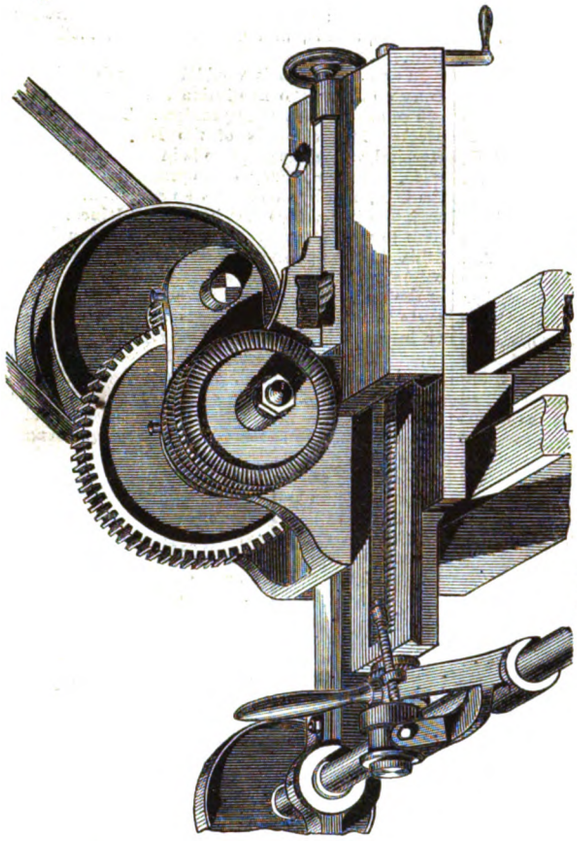

Fig. 1.—Machine for Gauging the Frames.

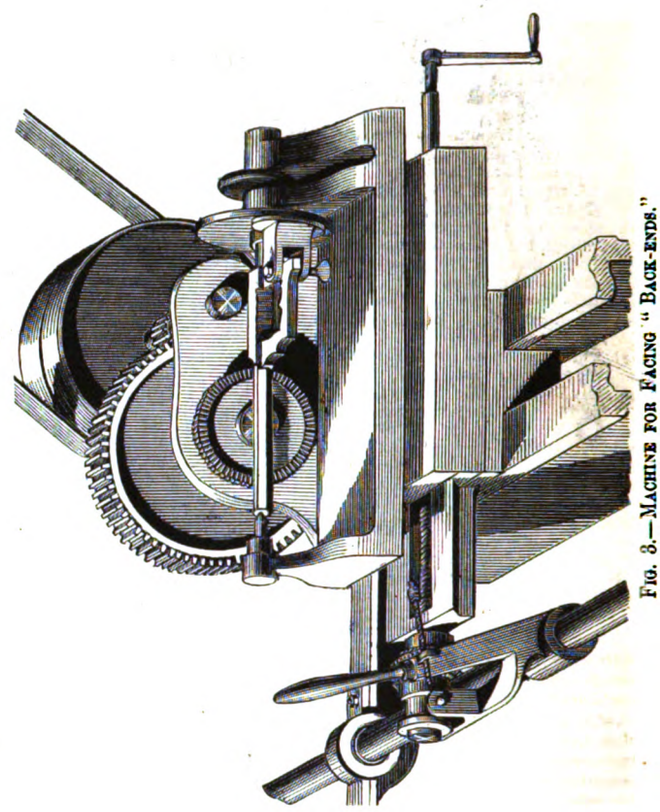

Fig. 3.—Machine for Facing "Back-ends."

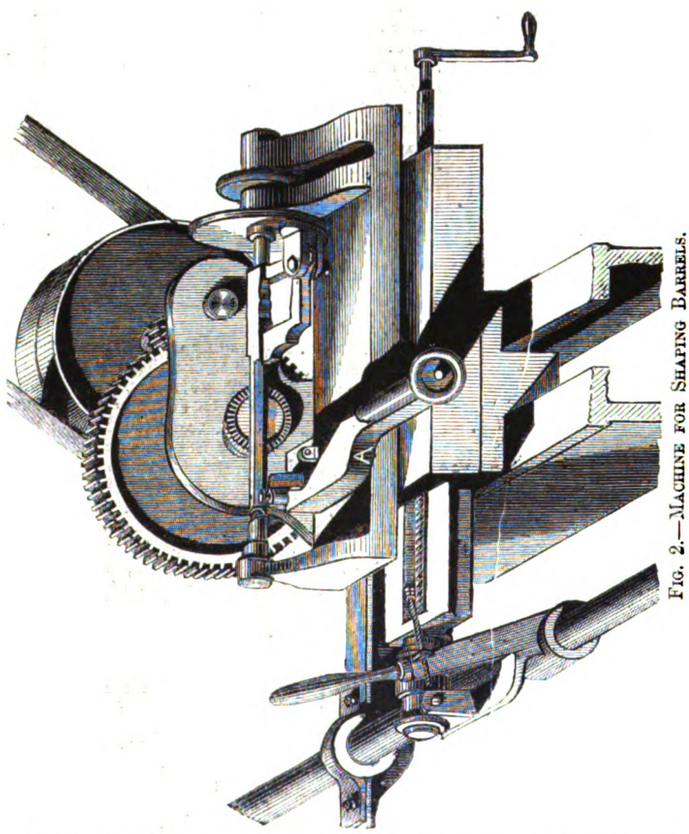

Fig. 2.—Machine for Shaping Barrels.

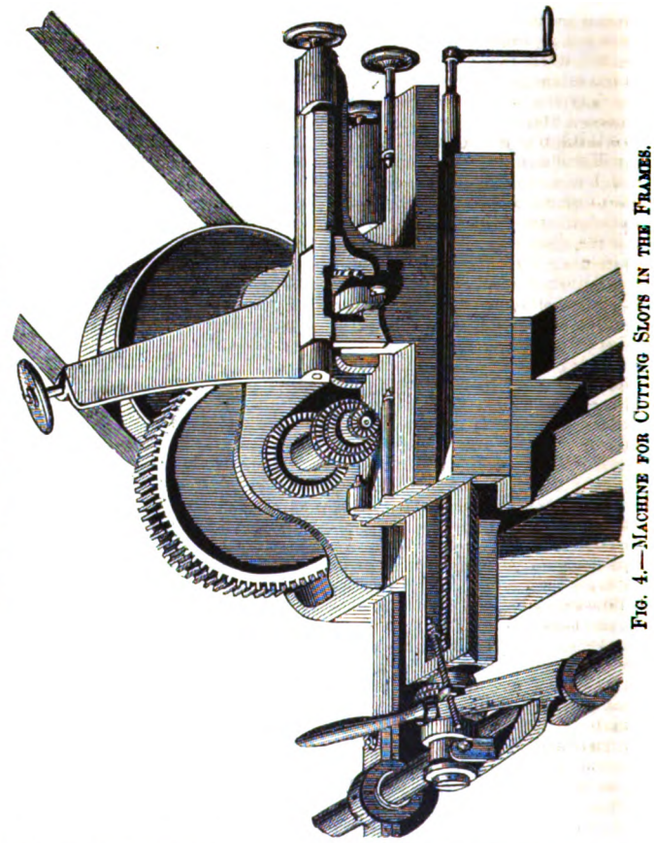

Fig. 4.—Machine for Cutting Slots in the Frames.

6. That it prevents smoky chimneys by the ample supply of warmed air to the room, and by the draught created in the neck of the chimney.

Mr. Galton believes that the principles adopted in these fireplaces are sound; they have been largely applied to military buildings, such as barracks and hospitals, and they have been recommended for introduction into workhouse wards. He recommends them to the attention of architects and builders, having the less hesitation in doing so, as there is no patent in question, and there is no one can claim any pecuniary interest in the manufacture of the grate.

THE GOVERNMENT BREECH-LOADING REVOLVER.

THE adaptation of the breech-loading principle to military rifles was very naturally followed by a general expression of opinion that the exigencies of the service required a similar change

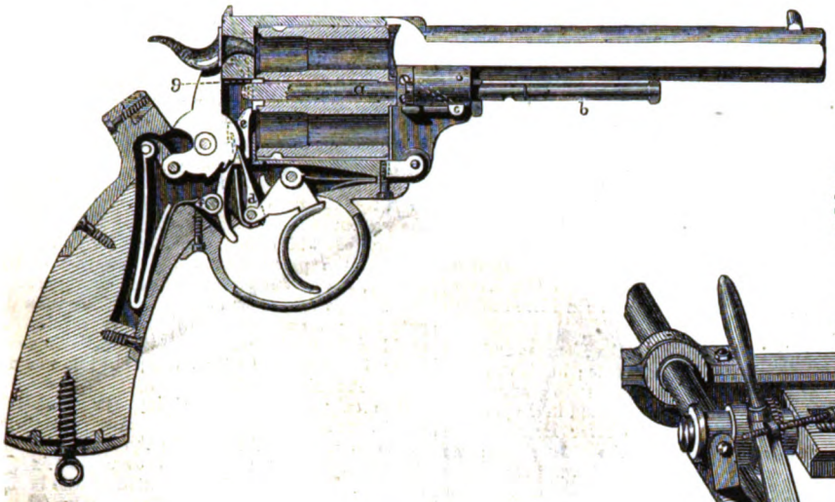
THE GOVERNMENT BREECH-LOADING REVOLVER.



MR. JOHN ADAMS' REVOLVER.

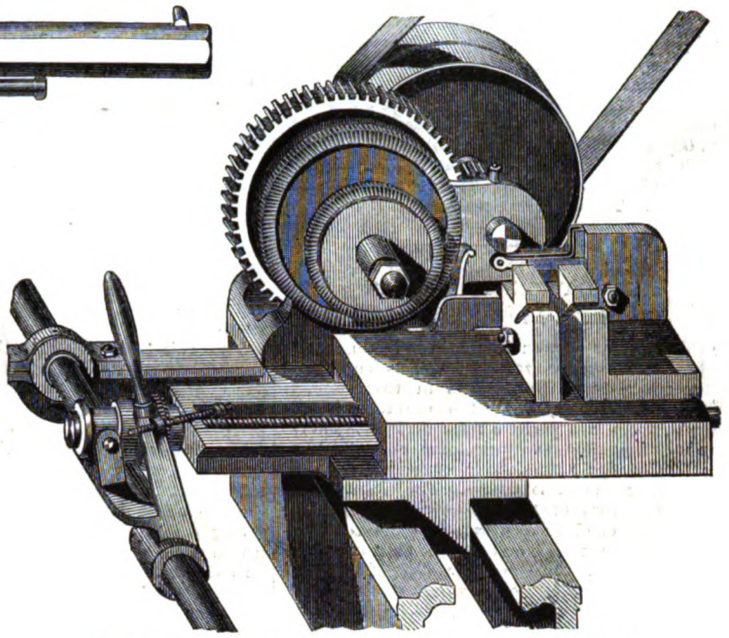


FIG. 5.—MACHINE FOR CUTTING SLOTS IN THE "BACK-ENDS."

in the revolvers in the hands of our navy. We have repeatedly pointed out the advantages which would accrue from such a change, and later on our popular contemporary, the "Pall Mall Gazette," went further, and while expatiating on the advantages offered by the breech over the muzzle-loader, commended the Government upon their choice of Mr. Adams' pistol, and the ammunition specially designed for it by Colonel Boxer. Since that time large numbers of these weapons have been made and many experiments conducted, all of which have proved the correctness of official judgment. We have much pleasure, therefore, in laying before our readers illustrations of the arm itself, and of some of the machinery employed in its manufacture, for the engraving and particulars of which we are indebted to the "Engineer" of last week.

We think that a mere inspection of our engraving will sufficiently explain the construction of the pistol, but we have nevertheless indicated some of the leading features by letters, thus:—*a* is the rod upon which the cylinder or breech chamber rotates, *b* is the ejector, *c* is the bolt for securing the ejector in its place when not in use, *d* is the lifting scear, *e* is the lifter, *f* is the scear, and *g* is the ratchet on the cylinder upon which the lifter acts. The cocking may be performed through the trigger or after the old plan; in the former case the trigger, when drawn back, raises the lifting scear *d*, which presses back the hammer until the point of the lifting scear escapes from its notch, and allows it full forward, the trigger at that moment pressing against the scear *f* and preventing it from engaging with the hammer. The rotation of the cylinder is performed by means of the lifter *e* engaging with the ratchet *g*, and the cylinder is locked during the instant of firing by the trigger, as shown in the woodcut. The cartridges are inserted at the side, and the opening is closed by a small shield hinged on to the "back end."

The barrel and frame are first forged together in one mass, best "Marshall's" being the iron employed. The blank is then centred at each end for a boring tool, and fitted in a template for the purpose of drilling out the square opening for the breech cylinder. The holes in the template through which the drill works are bushed with steel, and we understand they do not wear out so rapidly as might be supposed. The barrel is then drilled out by means of vertical drilling machines. Formerly ordinary horizontal drills were used, but they were not found to be nearly so satisfactory in their operation as the vertical, and required more lubricants.

After it is removed from the boring machine the barrel is laid on its back on the table of the machine, shown in fig. 1, which shapes the sides of the frame by means of two rose-cutters, and of course gauges them accurately. Fig. 2, another tool of a somewhat similar kind, cuts the polygonal faces upon the barrel, the blank being turned on its axis as each face is cut. The same machine squares the end of the frame, to do which the blank must be shifted to the holder A. All these machines are self-acting, but they can be thrown out of gear and the feed motion performed by hand if desired. Fig. 3 is a machine very similar to the last, and although our engraver has represented a barrel in the process of facing, this tool is more generally used for facing the breech-pieces or "back ends." For this purpose a number of them are secured in a frame, which in its turn is centred in front of the rose-cutter. We now come to the machine for cutting out the recesses for the lock, hammer, &c., shown in fig. 4. The barrel is first securely clamped on its back on the table and passed gradually under one of the rose-cutters, which works out the cavity in the frame for the trigger; it is then removed to the vertical frame, where it comes under the action of another cutter, which similarly cuts out the hammer slot; and lastly it is placed horizontally, as shown in the engraving, in which position the last and smallest cutter removes a portion of the metal at the side of the frame, behind the cylinder slot, for the lifter to work through. The tool shown in fig. 5 cuts out the two slots in the "back end," the larger wheel cutting out the slot to receive the frame of the pistol, and the smaller the cavity for the action.

The barrels are then placed in the rifling machine, where they are grooved to a pitch of one turn in 2ft. There are five grooves each $\frac{1}{4}$in. wide, with lands of 1-16in. These grooves are very shallow indeed in the centre, but deeper at the angles. The breech cylinders are forged solid, and consist of sections cut from a round bar. The blank is centred somewhat similarly to the frame previously described and then drilled through with a small tool, finished with a larger, and ultimately turned up in a lathe. The hammers and triggers are forged in dies, and after placing them in "jigs," which are frames or guides of steel hardened in oil, they are filed up by hand. The smaller cylindrical parts, such as the rod *a*, and the ejector, &c., are also made with rose-cutting tools fitted into ordinary lathes. It follows, of course, from the construction of so many parts by machinery, that out of a large number of pistols so turned out there should be a very small proportion of wasters, and this was found practically to be the case. The gauge of the barrel, as prescribed by the Government, is ·443in., and if any finished arm be found to possess a barrel into which a gauge of ·446in. can be inserted, it is at once rejected.

The efficiency of all breech-loading arms is, moreover, much dependent upon the ammunition, and we have no hesitation in stating that we have not hitherto seen any pistol ammunition which could excel that designed by Colonel Boxer specially for this pistol in efficiency and certainty. Cartridges for breech-loading revolvers have been almost universally made either on the pin-fire or rim-fire systems, both of which are open to objections. In the first, the projecting pin is a source of inconvenience, the cartridge is open to the chance of accidental explosion, and it has to be inserted in a particular position in loading. The rim-fire cartridge is frequently either weak at the rim, and bursts, or becomes compressed at the point of impact with the hammer and jams in the chamber, and in neither of these systems is the gas check satisfactorily accomplished.

The central-fire system has, however, none of these drawbacks, and, independently of the other advantages peculiar to the Boxer system, the ammunition for a revolver is materially improved by the adoption of this principle alone. As will be seen from the full-sized section of the cartridge for the Adams revolver, shown in our engraving, the base closely resembles that of the cartridge for the Snider rifle; but the body instead of being constructed of coiled brass, is simply a thin copper tube. The bullet weighs half an ounce, and is projected with a charge of half a drachm. We also give two diagrams of targets made at Woolwich

targets were made from a hand-rest with the service cartridge, "a very strong and gusty wind was blowing nearly across the range all the time."

We give the following extract from Captain Majendie's report:—"In making these targets the average time taken, including loading and knocking out the empty cartridge cases, was 45sec. for every six cartridges. Mean penetration of twelve shots at 30yds.—four ½in. elm boards 1in. apart; at 60yds., three ½in. boards. The revolver worked with perfect freedom throughout, and was no more fouled after firing 200 cartridges than after firing the first. There were no misfires."

IRRIGATION IN SPAIN.*

By MR. G. HIGGIN, M. INST. C.E.

THIS paper was on irrigation in Spain, chiefly in reference to the construction of the Henares and the Esla Canals in that country. It was stated that, of all the countries in the world, there was perhaps none that so much required irrigation as Spain, nor one which so gratefully repaid the labour expended upon it, by rich and valuable results. The climate of the south and east of Spain was suitable for the production of crops of almost all kinds: productions of the torrid and temperate zones here grow together. In the gardens of Murcia and Valencia might be seen wheat, barley, corn, maize, the orange, the lemon, the date palm, the olive, the citron, the peach, the pear, the apple, rice, pepper. In Malaga and Seville, in addition to these were the sugar-cane, the cotton-plant, the prickly pear, and, in sheltered spots, the plaintain, which was seldom found out of the tropics. The soil of most of the river plains was a rich alluvial deposit, from 3ft. to 10ft. in depth. Nothing was wanting but water; and this might frequently be seen a few yards off running to the sea, useless, and unproductive. A few charts of comparative rainfall and temperature had been prepared, which showed that, with the exception of Oran, Spain was by far the driest country. Thus, while Piedmont had a fall of 37in., Lombardy 38in., Algiers 27in., and Bône 25in., Spain had only an average of 17in; and in two cases, that of Madrid and Alicante, the mean annual fall was only 12in. and 13½in. respectively. The mean rainfall of Oran was 14½in. A comparison of the mean rainfall and temperature during the seven irrigating months from March to September, and the mean maximum temperature during June, July, and August, of Lombardy, Piedmont, and Spain, showed that, while Piedmont had a mean temperature of 63deg., and a mean maximum of 85deg., with a rainfall of 29in., Seville, with a mean temperature of 78deg., and a maximum of 111deg., had only a rainfall of 5½in. Madrid with a mean temperature of 65deg., and a maximum of 98deg., had a rainfall of only 5in. Alicante and Valladolid, though a little better than Seville and Madrid, were far inferior in rainfall, and superior in heat to either Lombardy or Piedmont. The vital necessity of irrigation was thus very apparent.

The earliest, and indeed almost all the, irrigation works in Spain were constructed about the year A.D. 800 or A.D. 900, when that country was under the dominion of the Moors. Perhaps the system of irrigation and the whole administration of the waters in Valencia and Murcia were as perfect as well could be, and the results were very surprising. It was not possible, however, within the limits of this paper, to give more than a cursory notice of these works; but such data were collected as would assist in the description of the new canals now in course of construction by the Iberian Irrigation Company. The areas of the several large irrigation districts in Spain were then detailed, amounting together to 680 square miles. According to the published Government returns, the total amount of irrigated ground in Spain was 4,439 square miles, so that it would seem that there was an area of 3,759 square miles irrigated from water wheel, small canals, tanks, &c., a quantity which was believed to be excessive. Admitting, however, that the returns were correct, even then only 4⅓ per cent. of the whole cultivated land was irrigated. While the rate of population in all Spain was only 81 to the square mile, in the irrigated garden of Murcia there were 1,681 inhabitants to the square mile, and in Orihuela 767 inhabitants per square mile.

The effect of irrigation was to raise the value of land ten, fifteen, or twenty times. Several illustrations of this were cited, and it was stated that, as a rule, all over Spain, good land in the valleys when unirrigated might be bought at an average price of from £6 to £10 per acre, while irrigated ground fetched from £80 to £120 per acre. In proportion to the value of the ground was the value of the water. Colonel Baird Smith gave the value of a cubic foot of water per second in Piedmont at £16 per annum, and in Lombardy at about £15 per annum. In most of the old systems of Spanish irrigation, the water was attached to the land, and was sold with it, and the value of the water could not, therefore, be ascertained. But perhaps the fair average value of a cubic foot of water per second in Spain might be taken to be that fixed by the Government for the Henares Canal, viz., £375 per annum, which was not considered a high price.

The projects for irrigating the Henares and the Elsa valleys were of very old date; but it was only during 1859 that the concessions were granted, and in 1863 that a company was formed in London to carry out the works. The river Henares rose amongst the mountains of the Somosierra: its course was extremely steep, and very rapid, the total fall of the river, from the weir of the new canal to Alcalá, a distance of 36 miles, being 407ft., giving a mean fall 11·3ft. per mile. The total length of the new canal was 28 miles. It received its water from the river at a point 16 miles above Guadalajara, just below the junction of the Sorbe and Henares, and ended at Alcalá. The area of ground capable of irrigation in this valley, after deducting that due to roads, streams, towns, &c., was 27,170 acres. For this purpose the volume of water conceded by the Government was 175 cubic feet per second for the nine months from October to June inclusive, and 105 cubic feet per second for the remaining three months. From accurate measurements made near the new weir since the commencement of the works, it appeared that during the months of July, August and September, the average quantity of water carried by the weir was 210 cubic feet per second, the lowest point which it had touched being 140 cubic feet per second. During the remainder of the year it carried an average of 300 or 400 cubic feet per second; but it was liable to enormous floods, and some came down during the progress of the works, which were estimated to amount to 8,000 cubic feet per second. The weir, it was calculated, would discharge 20,000 cubic feet per second.

The most difficult portion of the works was comprised in the first division—involving a rock cutting, 16ft. in depth, immediately after leaving the river; then a tunnel 3,171yds. in length through a high limestone cliffs, followed by a deep cutting in gravel. At the ninth kilomètre the canal crossed the Madrid and Saragossa Railway; and at the tenth kilomètre, a wide torrent bed. These were the ruling points in this section, and it was with reference to them that the actual height of the new weir was fixed. At the site chosen for the weir, the bed of the river was composed of compact clay rock, very impermeable, mixed with strata of excessively hard conglomerate. The front wall was built of rubble in hydraulic mortar, the foundation being benched into the rock. The main body of the weir was of hydraulic concrete; but in order to guard against filtration, a continuous line of cut stone was let into the rock in the centre of the concrete, all the stones being bedded in pure cement. The apron was entirely of cut stone, and from the top of the rubble wall to the crest, the weir was also of cut stone. The water for the canal was drawn off by five sluices, set in masonry arches, built of large blocks of rock-faced ashlar. At the entrance of the canal three sluices were fixed, for the purpose of scouring out any deposits which might accumulate in front of the gates. Immediately inside the head sluices, and forming a portion of the head works, there was an overflow weir, to provide for the discharge of any water which a sudden flood might admit into the canal during the absence of the guard. The weir was 130yds. long between the abutments, and its total cost, including all the head works and the waste weir, had been £17,343, or 50s. per cubic yard, as the mean price of the total cubical contents. Details were given of the prices paid for different classes of work, and of the materials employed. One flood, which came down when the weir was unfinished, tried it severely. The water rose 4ft. over the crest of the finished portion, completely filling up the gap, and pouring with great force on the exposed concrete hearting of the unfinished end. This flood was estimated to have a volume of more than 9,000 cubic feet per second, yet not a single stone was displaced.

The construction of the tunnel offered no engineering difficulties. About one-half of it was in a stiff, tenacious clay, the remainder being in limestone rock. It was found necessary to line the whole with brick, as the rock, though hard when first cut, crumbled under exposure to air and water. The bricks used were made in the valley, and, after a little trouble, they were obtained of a good quality, at a cost of £2 a thousand, delivered on the works. The whole of the brickwork was set in hydraulic mortar. As it was found, however, that the pure lime and sand set too quickly, the custom of the country was followed, and a percentage of white lime was mixed with the hydraulic, the proportions being one part of hydraulic, one part of white lime, and four parts of sand. This mortar was longer in setting than the pure mortar, and gave much better results. It could not be used where the work was liable to be immediately covered with water; but this was not the case in this tunnel.

The only other works of importance on this canal were an aqueduct over the Arroyo Tejada, at the entrance of the tunnel; the bridge under the railway; and the bridge over the Arroyo Majanar. The difficulties presented by the bridge under the railway were those due simply to the work having to be carried on without disturbing the passage of the trains. This was done by shifting the line, and building one-half of the abutments at a time. The railway was carried on wrought-iron girders sent from England. The canal was carried over the Torrent Majanar in a wrought-iron tube 66.6ft. span. When put together, complete, this tube was immediately filled with water to a depth of 5ft., and had since been kept full. It was perfectly tight, both at the joints with the masonry, and in other parts. With a load of 93 tons of water, it sank ¼in. in the centre. At the side of this tube were three sluices for discharging the canal, if necessary. The average prices paid for the smaller works, the manner in which the excavations were performed, and the class of labourers employed, and their pay, were then severally treated of.

The sections adopted for the first division of the canal had inside and outside slopes of 1½ to 1, and the banks were 6ft. wide on the top. The depth of water in the first few divisions was 5ft., and the velocity was 2ft. 4in. per second. This was rather high, but it was a matter of importance in Spain to avoid exposing the water in wide shallow channels, as with a less velocity weeds grew freely. Many of the old canals and watercourses of Spain had a mean velocity of 3ft. per second.

The Esla Canal, as regarded ease of construction, was perhaps one of the best in Spain. The whole estimated cost of the works, including a weir 191yds. long, was a little under £100,000; and for this amount 32,140 acres would be perfectly irrigated at a cost of £3 2s. per acre, while the cost per acre of the Henares Canal was £7 7s. The land in the Esla Valley was exceptionally rich; it was very thickly populated; and the only objection that could be made to it was its distance from any seaport.

One of the most interesting questions, in the construction of an irrigation canal, was the acreage which could be irrigated with a certain disposable quantity of water. Opinions varied very much upon this point. The amount supplied in different districts was given, and it was stated that, in Spain, the usual dotation for rice crops was considered to be 2½ litres per second per hectare. It had been found, by M. Ribera, from a series of experiments made near Madrid, that the quantity of water consumed in the irrigation of a nursery garden was 0·36 litre per second per hectare, and for a market garden 0·47 litre per second, in both cases the water being supplied without stint. The author had found, by experiment, based on the quantity of water actually employed by cultivators, also near Madrid, that ½ litre per second would irrigate one hectare every twelve days. This, it was thought, was quite sufficient for the cultivation of almost any crop except rice; and taking into account the fact that, in a large valley, such as the Henares, there must always be a great variety of crops, many of which would only require irrigation every twenty or thirty days, it was evident that ½ a litre per second was a good dotation for a canal. This, in English measure, amounted to one cubic foot per second for every 140 acres. The quantity allowed in India varied, it was believed, from 120 to 200 acres per cubic foot per second. The canon fixed by Government for the Henares Canal was equivalent to 3s. 9d. per irrigation of 450 cubic metres, and

*Read before the Institution of Civil Engineers.

Digitized by Google

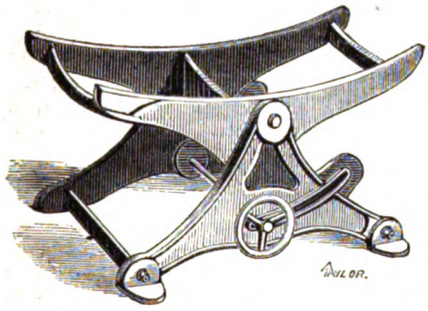
for the Esla Canal, 2s. 9½d. for the same quantity; the lower price, in the latter case, being due to the less expensive character of the works. Some particulars of the price of water in Spain were then furnished.

Several modes of measuring the water to be supplied to the land-owners were then described, including the system adopted by the Moors, the Milanese module, the plan followed on the Marseilles Canal, and a new method, by Lieutenant Carrol, of the Indian army, which had been tried on the Ganges Canal. The principal objects to be sought in a module were, simplicity of arrangement of the different parts, freedom from friction or any similar deranging cause, constant discharge under varying heads, and, of course, an exact measure of quantity. It was of great importance that there should be no concealed machinery, and also that the measure should be capable of being easily inspected by the landholders. The module adopted on the Henares and the Esla Canals could not lay claim to novelty; but it was believed it would fulfil its purpose practically. The water was measured by being discharged over a knife-edge iron weir, without any perceptible velocity, and when perfectly still. On the wall of the outer chamber was fixed a scale, whose zero point was at the level of the edge of the weir, and by means of this scale any person could satisfy himself that the proper dotation of water was flowing into the distributing channel. By arranging the sluice the guard could regulate to a nicety the height of water to be passed over the weir. Experiments were being made to ascertain the proper co-efficient for these weirs under varying heads.

As regarded the probable losses by filtration and evaporation, it was difficult to arrive at any reliable calculation, as different authorities gave such contradictory results. During the month of July, the water evaporated from the Henares Canal was equivalent to nearly ¾ per cent. of the whole volume. Another important point to the irrigation engineer was the principle followed in the distribution of the water. In the Henares Valley the ground was divided into plots of from 750 to 850 acres, each plot being served by one of the primary channels taken off direct from the main canal, one of the modules previously described being fixed at the point of departure.

NEW CASK STAND.

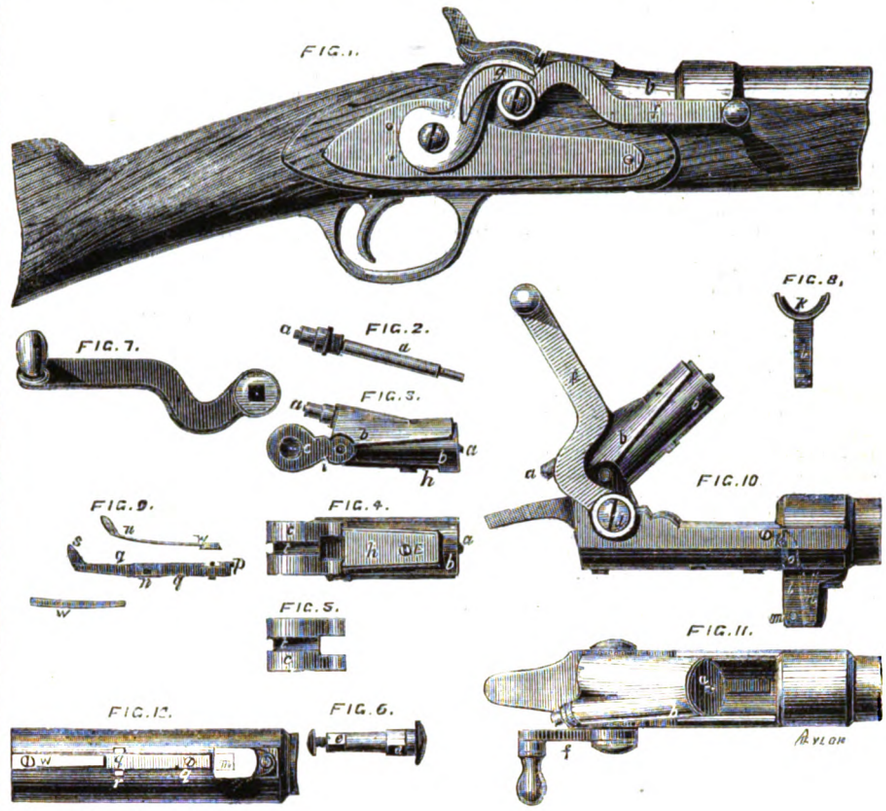
A VERY efficient cask stand has been invented by Mr. James Turnock, of Broad-street, Ross, Hereford, and which we show in the annexed cut. It is made of iron, and consists of



a lower and upper frame, the upper one being centred at the apex of the lower triangular frame, and fixed by the hand-wheel at the side. The upper frame is tilted over to receive the cask, which is easily lifted over into position for tapping, neither skids nor heavy lifting being required. The cask being on it is secured in position by turning the hand-wheel, which binds the two sides of the stand firmly together. For tilting the barrel the wheel is reversed, and the cask stooped over to the required position, and the wheel again tightened. This stand possesses many advantages; besides being small and compact, it enables the liquor to be drawn off clear to the last, as the motion of tilting causes no disturbance of sediment. It is also particularly adapted for cellars where room is an object, as it covers less space than the barrel it carries.

In the year 1867, 34,661 gallons of proof home-made spirits were removed from England to Ireland; and 1,115,766 gallons were removed from Ireland to England; 11,060 gallons were removed from England to Scotland, and Scotland favoured England with 3,600,440 gallons.

THE REILLY-COMBLAIN RIFLE.



THE competitive trials of breech-loading rifles has opened up a field for invention, of which due advantage has been taken. The result has been, and still is, the patenting of a vast number of ideas upon the subject, of which but few have found, or ever will find, their way into practice. Of the few which have been worked out, and have found favour with the public, the most recent example is the Reilly-Comblain rifle, which in its various details forms the subject of the accompanying illustration. It is a member of that system in which the breech-block is drawn back and turned up on a hinge. The hammer by the same movement is cocked or half-cocked by means of a lever at the side of the gun. There is also an arrangement for extracting the empty cartridge case. In our engraving, fig. 1 is a view of a portion of the right hand side of the gun with the parts in the position they occupy after the discharge; figs. 2 to 9 are views of various parts detached, to which we shall presently refer; fig. 10 is a side view; and fig. 11 a top view of the breech portion of the gun with the parts in the position they occupy, when the breech is open for the insertion of the charge; fig. 12 is a view of the underside when the gun is ready for firing.

The exploding pin *a*, fig. 2, is fitted in a breech-block *b* (shown in side view in fig. 3 and in bottom plan in fig. 4) similar to that used in the Snider gun; this block is, however, not hinged to the side, as in the Snider, but is hinged at the back to one end of a link *c* (shown detached in fig. 5). This link receives at its other end a square part *d* of an arbor or strong pin (shown detached in fig. 6) passed transversely through the stock, while another square part *e* of the arbor is received by the rear end of the lever *f*, which is shown detached in fig. 7. This lever is bent near its rear end to bear against a projecting part *g* of the hammer, as seen in fig. 1. As the lever *f* is being raised by its knob into a vertical position or a little beyond, as seen in fig. 10, its bent portion presses against the projecting part *g* of the hammer, putting it at full or half-cock. This movement of the lever moves the arbor (fig. 6) round, and consequently the link *c*, thereby drawing back the breech-block *b*. When the link *c* has moved a certain distance a projection or spring plate *h* on the underside of the breech-block takes into a notch *i* in the link, so that the block *b* partakes of the further movements of the lever and link, and is thereby raised into an inclined position, clear of the opening behind the barrel, as seen in fig. 10.

The arrangement for extracting the cartridge case consists of an ordinary curved extractor *k* (fig. 8) on the top of a vertical bar *l*, which is pivoted at its bottom at *m* (fig. 10), and is continually pressed upon in front by a spring *n*. A notch *o* at the top of the bar *l* receives, when the parts are in position, a projection *p* on the front of a bar *q* (fig. 9) pivoted at *r*, and lying in a longitudinal recess in the under side of the block chamber, as seen in fig. 12. The rear *s* of the pivoted bar *q* is turned upwards, and when the breech is opened a grooved part *t* of the under side of the link *c* presses upon the turned-up portion *s*, thereby lowering the rear of this bar and lifting up its front end *p* from the notch *o* of the extractor bar. The extractor *k* being thus released, it is suddenly moved back by its spring *n* a short distance, so as to eject the cartridge case, which then comes against a curved spring *u* on the upper side of the pivoted bar *q*, and is thus directed clear of the gun. This spring, however, is now done away with, and in the rifles now made by Messrs. Reilly the spring *u* and the pivoted bar *q*, instead of being in two pieces, are formed in the solid. This improvement simplifies the working parts, and does away with an objectionable spring. When the breech-block *b* is returned to its chamber, a spring *w* causes the pivoted bar *q* to again enter the notch *o* of the extractor bar.

It will be seen that the action of this rifle is exceedingly simple, and, having one of these rifles at hand, we can answer for its easy manipulation. There are but three motions—opening the chamber which cocks the piece, inserting the cartridge, and closing the chamber for firing. We have not yet tried the arm, but Messrs. Reilly, of 502, New Oxford-street (to whom we are indebted for our particulars), inform us that the trials made by them have proved highly satisfactory. Out of one rifle they have had 500 consecutive shots, the action working well, and no hitch occurring. We may add that these rifles are now being made in considerable numbers, and we think its merits entitle it to a favourable reception by the public.

THE Council of the Royal Society recommend the following gentlemen for election to the Fellowship:—J. Ball, H. C Bastian, M.D.; Lieutenant-Colonel J. Cameron, R.E.; Professor R. B. Clifton; M. W. Crofton, J. B. Davis, M.D.; P. M. Duncan, M.D.; P. Griess, A. G. V. Harcourt, Rear-Admiral A. C. Key, Rear-Admiral E. Ommanney, J. B. Pettigrew, M.D.; E. J. Stone, Rev. H. B. Tristram, W. S. W. Vaux.

AERONAUTICS AT THE CRYSTAL PALACE.

WE have more than once drawn attention to the approaching aeronautical exhibition at the Crystal Palace, and we now append the latest detail particulars for the information of those of our readers who may intend to exhibit. For fuller particulars we refer our readers to the MECHANICS' MAGAZINE of the 30th of March last, page 217. The exhibition will be opened on Thursday, the 25th of June. There will be no charge for space. Each exhibited article must be accompanied by a large card or placard in duplicate, having conspicuously printed its name and object. Goods will be received at the Crystal Palace on and after the 1st until the 20th of June, unless the term be prolonged by special arrangement. A description of the articles intended for exhibition, not exceeding 100 words, must be sent to Mr. F. W. Brearey, the hon. sec., on or before June 1, for insertion in the catalogue. Fuller particulars will be charged for. Intimation should also be given within this date of any exhibitor's desire to explain his invention, either in person or by deputy. In addition to the prizes already announced, smaller prizes, as far as the guarantee fund will allow, will be given to exhibitors of other machines, according to merit. Two members of the Aeronautical Society, viz., Mr. Thos. Brassey and Mr. Stephen Ballard, C.E., have contributed £20 each to increase the prize for light engines.

During the exhibition, daily experiments and partial ascents will be made in a captive balloon, upon the plan lately pursued in Paris by Mons. Giffard. Messrs. Domange and Delamarne's "Ballon Captif" has been engaged for this purpose, under the management of Mons. Delamarne, who will inflate it with gas especially manufactured under his superintendence; and it is proposed to make successive ascents to at least 1,000ft. The car of this aerostat is 3yds. square, and will accommodate fourteen persons. Mr. Glaisher will largely avail himself of the opportunity here afforded for meteorological experiments during the captive ascents both by day and night. During the latter the power of the magnesium lamp will be tested, both as to the distance from which it can be seen at different elevations, and its own powers of illumination. Similar experiments not confined to the magnesium light will be conducted. Each member of the Society will be entitled to an ascent during the daytime free of charge. Applications for a ticket, to admit members only, to be made to the hon. sec., who will also, upon application, furnish a free pass to the exhibition. Balloons for free ascents, it is hoped, will also be held in readiness, under the guidance of experienced aeronauts, for the accommodation of visitors, who may engage to make an aerial excursion.

WATER-CART FOR THE CITY OF LONDON.

THERE are several defects in the water-carts at present in use; for instance, whether much or little water be required to be spread over a given space, and whether the level of the water be high or low, it always obtains exit by passages and holes of the same sectional area, and of dimensions that are unalterable to suit the circumstances of the case. The body, too, is placed at once on the frame of the cart, which is fixed to the axle of the wheels, thus affording no spring to ease any sudden concussion to which the cart is liable when in use. Further, the body of the cart is apt to rust, from its constant exposure to the joint influence of air and water, whilst the strains and concussions to which it is subjected during use, from rugged roads, the varying quantity of water, and from other causes, tend to loosen the rivets and to promote leakage. We, therefore, gladly draw attention to an improved water-cart, which has been designed by Messrs. Bayley and Rawsthorne (late Braby and Son), of the Patent Steam Wheel Works, Newington Causeway, Southwark.

Taking the above objections seriatim, we find, in the first place, the amount of flow from the body of the cart regulated by a simple arrangement. A main or branch pipe, bent in the usual quadrantal form, proceeds from the bottom of the body to the middle of the horizontal distributing pipes, of which there are two, one above the other. The main pipe is divided into two chambers by a longitudinal metal diaphragm, and the distributing pipes are each in exclusive communication with one of these chambers. Underneath the ordinary valve of the main pipe is a revolving disc valve, having nearly one-half of its area cut away, so that the opening thus formed may be over one or other of the two chambers. According to the position of the valve the water is admitted to the upper or lower distributing pipe, or to both, and as the upper distributor has double the number of holes the lower one has, the quantity of water distributed in a given time can be perfectly regulated within certain known limits. This is a very important feature, as it enables a larger supply of water to be delivered on newly-made roads, where it is most needed. In the next place, Messrs. Bayley and Rawsthorne have introduced springs. By this means the body of the cart is preserved, to a great extent, from the effect of blows and sudden concussions. By submitting the body of the cart to the process of galvanization oxidation is prevented.

Not only in details does this cart differ from the ordinary water-cart, but in general construction, the appearance being certainly greatly improved. The cart is hung on a cranked axle, which brings it very near to the ground, so that the flow of water lays the dust better than if thrown from a greater height. The driver sits on the top of the cart, and governs the flow of water in the usual way. The valve is regulated before starting on the journey from the interior of the cart, where it is set to either the slow or the quick flow according to the requirement. Altogether, the arrangement of this cart is most satisfactory, and a recent inspection at Messrs. Bayley and Rawsthorne's works of one of a number now being built for the City of London convinces us that the Corporation have taken a step in the right direction in adopting these improvements.

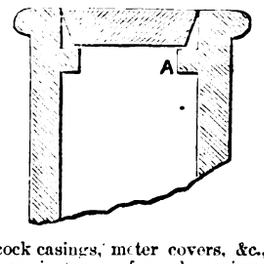
Whilst looking round Messrs. Bayley and Rawsthorne's works, we noticed the excellent patent wheel and axle with which they fit all the carts and waggons they turn out, which are not a few. In fact, the wheel is now universally adopted by leading firms in London, and is extensively supplied to the provinces and the colonies. The wheel is made with a cast-iron nave, the inner surface of which is case-hardened. The nave is cast in one piece, with the necessary sockets to receive the ends of the wooden spokes, and with chambers for the lubricating material. The axle passes through the nave, and is secured by a metal screwed nut. At the outer end of the axle a flanged hollow hemispherical cover is secured to the nave by screw bolts, and has a hole for the supply of the lubricating material to the axle. The hole is closed by means of a screw, and the cap-piece protects the nave from concussion. An india-rubber washer placed between the flange of the cap and the iron nave prevents leakage of the lubricating material. The wheel altogether is superior in appearance, durability, and ease of draught. The bearing being shorter than in the case of the wooden stock wheel, there is less friction on the axle, and as the iron nave does not project so far as the wooden stock, there is less liability to accident in narrow or crowded thoroughfares. As regards the improved draught, it is found in practice, by a large user of horse power, that the patent axles make a difference of half a horse-power in every van. We may add that the prize medal was awarded in 1862 for this axle.

Correspondence.

LINCOLN WATERWORKS COMPANY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—In your report of the paper read before the Society of Engineers on the 6th of April, by Mr. Sydney A. Reade, I noticed, on page 293 of your current volume, the common complaint of the tightening of manhole covers by the grit being pressed down into the marginal space. I tried some years since to obviate this inconvenience with a projecting flange, and also by means of a cap, but neither method was at all satisfactory. I then adopted the method shown in the accompanying sketch for fire



plug and cock casings, meter covers, &c., and have never had an instance of one becoming tightened. The evil arises from the whole of the sides being parallel the entire depth of the cover, but by simply tapering the sides of the cover this evil is entirely prevented, and if a few slots are made in the interior projection A the space is kept comparatively clean. The reasons are obvious; the grit having passed through small spaces above is again free to fall from the tapered cover, giving more room. I have shown it more conical than is adopted in practice, for the sake of making it clear. Should you think the above useful for your numerous readers, in removing, at times, a very serious evil, you will no doubt give it publicity.—I am, Sir, yours, &c.,

HY. TEAGUE.

Engineers and Managers' Office,
May 6.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—W. B.—H. T.—E. H. C.—J. C. S.—A. J.—W. W.—E. C. P.—Messrs. G. and B.—J. E.—Messrs. B. and Son—F. W. B.—T. B.—J. B. T.—R. J. G.—J. H. W.—J. B. D.—S. K. M.—P. G.—J. H.—F. W. B.—J. F.—W. T. Meetings for the Week.

MON.—Royal United Service Institution.—Mr. Samuel Mackie on "The National Defences of Great Britain, Especially with Reference to the Future Requirements of Floating Forts," at 8.30 p.m.

Royal Institute of British Architects.—M. Digby Wyatt on "The Foreign Artists Employed in England During the Sixteenth Century, and their Influence on British Art," at 8 p.m.

TUES.—The Institution of Civil Engineers.—Discussion on "Engineering Philosophy. The Durability of Materials," by Mr. Edwin Clark, M.I.C.E., at 8 p.m.

Royal Institution.—Dr. Foster on "The Development of Animals," at 3 p.m.

THURS. — Royal Institution. — Professor Grant on "Astronomy," at 3 p.m.

FRI.—Royal Institution.—Professor Odling on "The Rapid Decomposition of Water, and other Effects of the Heat of the Oxy-hydrogen Flame," at 8 p.m.

Royal United Service Institution.—Mr. Mansfield Parkyns on "Abyssinia," at 3 p.m.

SAT.—Royal Institution.—Professor Grant on "Astronomy," at 3 p.m.

Naval, Military, and Gunnery Items.

THE annual regimental dinner of the Royal Artillery is appointed to take place at Willis's Rooms on the 1st of the ensuing month, at which the Duke of Cambridge will preside.

IT is announced that an order has been received at New York from Athens for the construction of an armour-plated vessel for the Cretan Navy. The vessel is to be built at once, at a cost of 1,500,000 dollars.

A NEW battery has been erected at Shotley, Suffolk, and fourteen new Armstrong guns of 7½in. calibre have arrived from Woolwich. The erection of new barracks at Shotley is also understood to be in contemplation.

A RECENT letter from Bombay informs us of the death of Captain Young, C.B., at Kurrachee. We also learn that the two transport ships employed on the Bombay side have to undergo extensive repairs each time they return to Bombay. Who's to blame for this little expense?

A LARGE number of mechanics and other workmen are employed at Chatham Dockyard in preparing the turret ship "Monarch," for launching on the 25th instant. The whole of her armour-plating has been bolted to her sides and finished off, leaving only the 10in. armour plates to be fixed to her turrets.

A RECENT "Gazette" contains a warrant revising the Royal warrant of January 16, 1861, and ordering that officers of the land forces serving in India under the rank of regimental field officer, who shall have

Digitized by Google

served two years with a regiment, of which one shall have been in India, shall be eligible to enter the Bengal, Madras, or Bombay staff corps.

ACCORDING to the "Moniteur de l'Armee," platoon firing with the Chassepot gives prodigious results. At 200 metres (220yds.) 70 per cent. of the bullets hit the target; and at 300 metres (330yds.) the proportion is 62 9-10 per cent. This is very good practice indeed, but it gives no clue to the real practice in action.

THE first of a fleet of small screw steamers, building for the Imperial Ottoman Government, was launched on Saturday from Mr. John White's shipbuilding-yard, at Medina Dock, West Cowes. The vessel, which is named the "Sahir," is 119ft. between perpendiculars, 20ft. in breadth, 11ft. 10in. in depth of hold, and measures 225 tons o.m. Her engines will have a combined nominal power of 50-horse, and have been made for her by Messrs. A. Day and Co., of Southampton.

AT the battle of Turin, fought on July 14, 1706, a Prussian regiment, part of the contingent which, under the orders of the Prince of Anhalt-Dessau, formed Prince Eugene's left wing, greatly distinguished itself, and by its valour, it is said to have greatly contributed to the capture of the French intrenchments, and the complete victory obtained. The colours of that regiment, in whose folds its old and gloriously traditions are still enveloped, are now those of the 1st Regiment of Prussian Grenadiers, of which the Crown Prince is the Colonel.

THE "Gazette" of last Friday notifies to the persons interested that the distribution of the award for salvage service rendered to the barque "Mewah," between the 3rd and 8th December, 1866, by her Majesty's ship "Wasp," will commence to-morrow, the 16th instant, in the Prize Branch of the Department of the Accountant-General of the Navy. Shares: Captain, £229 2s. 3d.; second class, £64 4s. 2d.; third, £55 0s. 9d.; fourth, £36 13s. 10d.; fifth, £22 0s. 4d.; sixth, £18 6s. 11d.; seventh, £12 16s. 11d.; eighth, £7 6s. 9d.; ninth, £3 13s. 4d.; tenth, £1 16s. 8d.

A BOARD of Trade return shows that in the year 1867 £34,850 was received from masters of vessels, collectors of customs in the colonies, and consuls abroad, for wages and effects of 5,547 deceased seamen. In the course of the year sums amounting to £24,269 were paid to the relatives and representatives of 2,732 deceased seamen. The amount unclaimed received before 1861 has been paid into the Exchequer, leaving an unclaimed balance to meet claims as they may be established, amounting to £81,124, partly in Exchequer bills, and partly cash, in the hands of Her Majesty's Paymaster-General.

THE twin screw gunboat "Bullfinch," 663 tons, 170ft. in length, and 29ft. beam, lately launched at Sheerness, was recently taken on a trial of her engines, off the Maplin Sands. The ship was in charge of Captain the Hon. A. Cochrane, C.B., of the Sheerness Steam Reserve. Several trials were made on the measured mile, giving a satisfactory speed of 11·011 knots. The engines are of the nominal power of 160 horses, but were worked up to 917 horses. The two screw propellers are of the Mangin pattern; diameter, 7ft. 3in.; pitch, 11ft. 4½in.; and immersion of the upper edge, 12in. The draught of water was 8ft. 10in. forward, and 10ft. 2in. aft. The revolutions were 132 per minute; vacuum, 24; pressure of steam, 28lb.

DURING the time the steam dredging machine was at work in Chatham harbour, clearing away an obstruction near the entrance to the third dock, in which the "Monarch" is building, the machine came in contact with the hull of an old vessel, which is believed to have sunk in the river upwards of a century since. Attempts have since been made to remove the obstruction by charges of gunpowder, for which purpose divers of the Royal Engineers have been down, and placed the charges beneath the vessel's bottom. The explosion of the powder has however, had very little effect on the hull of the vessel, as only a few of the timbers have been blown up, and attempts are now being made to raise the obstruction by means of large mooring lighters. It is a singular circumstance that the existence of a sunken vessel so near the outlet of one of the docks does not appear to have been known to any of the dockyard officials.

Miscellanea.

COLONEL W. H. Sykes, M.P., was, on Wednesday, unanimously re-elected chairman of the East India Company for the ensuing year.

VALUABLE coalbeds have been discovered in the line of Capetown and Wellington Railway. The Government has authorized explorations to be made.

THE number of visitors to the Patent-Office Museum, South Kensington, for the week ending May 9, was 2,819; total number since the opening of the museum, free daily (May 12, 1858), 1,295,712.

IN the week ended on Monday, upwards of 250 tons of mackerel were despatched from West Cornwall by rail, by far the greater portion of this immense supply being sent to London.

THE select committee of the House of Commons to which the Liverpool Tramway Bill was referred has declared the preamble to have been proved. The line passes from north to south of that borough.

THE trustees of the British Museum have appointed Dr. Cobbold, F.R.S., to hold the chair of geology for the next term of five years, and they require that the first annual course of twelve lectures be given in Edinburgh.

A SUM of £1,500 has been subscribed for the purpose of erecting a statue to the memory of the late Earl Rosse. The committee are about to communicate with Mr. Foley, the eminent sculptor. The statue is to be erected in Parsonstown.

AT a meeting of the Curators of the University of Edinburgh, held on Thursday week, it was resolved to proceed with the election of a Principal, in room of the late Sir David Brewster, on the 18th of June, the day on which the election of Professor of Moral Philosophy is appointed to be held.

AN extensive mountain slip took place a few days back in the village of Oberbilten, canton of Glaris, in Switzerland. The inhabitants, warned in time, had left their houses, which, for the most part, have been overwhelmed. Large masses continue to fall, accompanied by loud reports.

THE number of Cornish pumping engines reported for March is 22. They have consumed 1,758 tons of coal, and lifted 153·9 million tons of water 10fms. high. The average duty of the whole is, therefore, 53,300,000lb., lifted 1ft. high, by the consumption of 112lb. of coal.

WE have just received from Messrs. Turgan, of Paris, the 143rd and 144th numbers of "Les Grandes Usines," which contain some excellent practical remarks on the manufacture of woollen fabrics at Rheims, and to which we shall more specially refer in a future number.

THE annual conversazione of the president of the Institution of Civil Engineers will be held on Tuesday evening, May 26th, when the co-operation of members and visitors is requested, in order that a collection of models of engineering construction and of works of art, worthy of the Institution, may be obtained.

THE Ohio Legislature has passed a bill authorizing a bridge across the Ohio to connect Cincinnati with Newport, Ky. The span over the main channel is to be 500ft. in length, and the adjoining span 220ft. each, a height in the centre of 100ft. in the clear above low water. A company to build the bridge is incorporated.

ACCORDING to the "Liverpool Albion," about ten p.m. on the 4th inst., as No. 11 pilot boat was cruising off the Welsh coast, near Puffin Island, at the entrance of the Menai Straits, the pilots observed a star become blood red, and expand. The phenomenon continued for half an hour, and excited intense interest among the pilots, who were observing it through their telescopes.

HER Majesty's Government, with a view of constituting a separate Department of Science and Art for Ireland, analagous in its constitution to the existing Science and Art Department in London, and of amalgamating, as far as possible, all existing institutions in Ireland receiving State grants for science or art, have appointed a commission to report on the best means of carrying out this object.

THE council of the Royal Agricultural Society recently received three deputations—one from Liverpool, another from Manchester, a third from Preston—inviting them to make each of those several towns the site of the society's meeting in 1869. After listening to the representations of the several deputations, the council decided in favour of Manchester by twenty-five votes against eighteen in favour of Preston. No vote was given in favour of Liverpool.

THE "Moniteur de l'Algerie" says:—The subdivision of Aumale mentions the first appearance of locusts. The disposable troops have been directed towards the points threatened, and all the inhabitants have been put in requisition. A sum of 2f. 50c. is given for every 1cwt. of insects destroyed. The invasion in this quarter seems to be checked. Round about Boghar crickets are more or less numerous, and similar measures are adopted.

THE visitors to the South Kensington Museum during the week ending May 9, 1868, were as follows:—On Monday, Tuesday, and Saturday, (free), from 10 a.m. to 10 p.m., 9,521; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,879. National Portrait Exhibition, by payment, 2,738; Total—14,138. Average of corresponding week in former years, 11,494; total from the opening of the museum, 7,373,480.

IN Southern France the railways are seriously embarrassed every winter by snow drifts filling the deep cuttings, but the past season a section of the line of railway from Saint Etienne to Annoway has been kept open by the judicious planting along the banks on either side of the track, of pine trees, a system of treatment previously adopted in arresting the dunes, or inroads of sea sands, which in many parts of France used to annually cause great damage.

AT the monthly meeting of the committee of the Newspaper Press Fund, held at the offices in Cecil-street, Strand, on Saturday, the Right Hon. Lord Houghton, president, in the chair; Sir Moses Montefiore, Bart., F.R.S., Mr. Lionel Lawson, and Mr. Edward Levy were elected vice presidents. The secretary, Mr. Taunton, reported a preliminary list of 163 stewards for the anniversary dinner on the 6th June next, under the presidency of His Royal Highness the Duke of Cambridge.

A RETURN has just been issued which shows that in the year ending March 31st last the income of the British Museum amounted to £126,754 17s. 6d., made up as follows:—Balance from previous year, £25,889 3s.; parliamentary grant, £99,621; sale of old metal and soot, £52 1s. 10d.; dividends on stock, £900; sale of guide books, &c., £292 12s. 8d. The expenditure for salaries, purchases, printing, buildings, &c., amounted to £98,274 3s. 3d.; to continue excavations at Ephesus, £830; Abyssinian expedition, £174 7s.; for the Woodhouse collection, £1,360; the balance at the end of the year being £26,116 7s. 3d.

AT the close of the year 1866 there were in England and Wales 283 railway companies whose lines were open for traffic, with a total mileage of 9,701, of which 16 companies alone owned, leased, or worked 8,481 miles. In Scotland at the same period there were 31 companies with 2,244 miles of railway open for traffic; and in Ireland there were 39 companies, with a total mileage of 1,909. Nine bills have been introduced during the present session of Parliament, authorizing amalgamations which, if carried out, will add 540 miles to our present railway system; and it is proposed to add 85 more by 14 bills laid before Parliament containing provisions for working arrangements.

THE following gentlemen have satisfactorily passed the final examination in physical science, held in April last, under Sir William Thomson, in the order annexed, and have commenced the course of instruction in practical telegraphy, with the view to service in India. Messrs. Ayrton, University of Glasgow; Maclean, Hartley Institution, Southampton; Smyth, Trinity College, Dublin; Boyd, Hartley Institution, Southampton; Congdon, Hartley Institution, Southampton; and Landon, Hartley Institution, Southampton. Messrs. Ayrton, Maclean, and Smyth, having passed a distinguished examination, have been awarded a premium of £50 each.

FOR welding iron and steel a composition has lately been patented in Belgium, consisting of iron filings, 1,000 parts; borax, 500; balsam of copaiva, or some other resinous oil, 50; and sal-ammoniac, 75. They are mixed, heated, and pulverized. The process of uniting the iron and steel is as usual. The parts are heated to a cherry red, covered with the preparation, brought together, again heated and welded. Another composition for the same purpose is 15 parts of borax, 2 of sal-ammoniac, and 2 of prussiate of potash. Being dissolved in water, the water should be gradually evaporated at a low temperature.

A MOST interesting addition to the attractions of the Crystal Palace has just been made by an ants' nest, found within the last few weeks by Mr. Robert Holt, under the floor of his house at Lower Norwood. Mr. Holt, who is the lessee of the French Court in the Crystal Palace, has taken care to preserve this nest in its integrity, as found, and it is now placed on a marble pedestal, in front of the French Court, where it attracts great attention. The nest, which appears to have been formed of masticated wood, it is about 12in. square, and is full of perforations as the nests of other insects, and the ants who have created it may be seen swarming in and out of the nest, and up and down the pedestal with their proverbial activity.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3035, 3042, 3051, 3070
BUILDINGS AND BUILDING MATERIALS—3080
CHEMISTRY AND PHOTOGRAPHY—3057, 3064
CULTIVATION OF THE SOIL, including agricultural implements and machines—3022, 3043, 3049, 3052, 3067, 3073
ELECTRICAL APPARATUS—None
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3033, 3046, 3048, 3053, 3063, 3081
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—3069
FURNITURE AND APPAREL, including household utensils, fire-keepers, jewellery, musical instruments, &c—3044, 3068, 3077, 3079
GENERAL MACHINERY—3011, 3014, 3016, 3017, 3030, 3031, 3034, 3040, 3045, 3047, 3050, 3055, 3059, 3062, 3065, 3072 3076, 3078, 3087, 3090

Digitized by Google

LIGHTING, HEATING, AND VENTILATING—3060
METALS, including apparatus for their manufacture—None.
MISCELLANEOUS—3015, 3018, 3020, 3021, 3024, 3032, 3036, 3037, 3038, 3058, 3066, 3074, 3082, 3083, 3084, 3085, 3086, 3088, 3089
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—3026, 3054, 3071
SHIPS AND BOATS, including their fittings—3027, 3028, 3056, 3061
STEAM ENGINES—3012, 3023, 3025
WARFARE—3019, 3039, 3075

3011 B. COOPER. *Improved machinery for removing knots, burls, and other extraneous substances from woollen cloth, flannel, and other fabrics.* Dated October 25, 1867.

This invention is not described apart from the drawings. —Patent completed.

3012 J. A. and J. HOPKINSON. *Improvements in steam engine indicators.* Dated October 26, 1867.

This invention consists, in the first place, in the use of a continuously revolving barrel on which the diagrams are taken, such barrel being connected with any required part of the engine, and caused, by means of suitable connection, to make either an equal, or quarter, or less number, of revolutions than the engine, as may be required. The invention consists, in the second place, in an improved pencil holder, which contracts or expands by the motion of the piston or other part to which it may be attached. The invention consists, in the third place, in dispensing with the ordinary slide or slides in direct-acting steam engine indicators, by connecting the "lazy tong" pencil holder with the top of the piston rod, over which is fixed a bent pillar or support for fixed centre.—Patent abandoned.

3014 G. and E. DORSETT and J. B. BLYTHE. *Improvements in the mode of, and apparatus for, burning the gases arising from the distillation of liquid hydrocarbons, and also in economizing fuel by the said process.* Dated October 26, 1867.

According to one portion of this invention, the patentees burn the gases produced by the distillation, by heat of liquid hydrocarbons, such as coal tar, creosote, coal, and shale oil, petroleum, and other matters of a like nature, in the following manner:—They cause the gas produced from the matter under distillation (such as coal tar, at that stage of the process in which the heavy oil has commenced to run from the worm), to pass through a pipe commencing at the top of the boiler, generator, or retort, and terminating in the ashpit or furnace. They there burn it, either by allowing it to pass through the fire, on the gratebars, or through a burner formed with a series of holes, or upon a diaphragm, as in the case of the ordinary gas burners used for cooking. This part of the process is particularly adapted for application under tar and petroleum stills.—Patent completed.

3015 W. E. WILEY. *Improvements in holders for lead and other marking materials, part of which improvements is also applicable as holders for other articles.* Dated October 26, 1867.

This invention has for its object improvements in holders for lead and other marking materials, part of which improvements is also applicable as holders for other articles, and relates, first, to an improved holder for cedar or other wood pencils or marking instruments. For this purpose the patentee employs a case or holder having a longitudinal slit or opening formed therein as usual, and at one or both ends he forms a short transverse slit or opening, running into the aforesaid longitudinal slit, one or both of such transverse slits communicating with a cut running entirely to the end of the holder. In connection with such holder he employs a common cedar or other wood pencil or marking instrument having a pin or stud fixed in the end thereof. By these means the marking instrument may be readily inserted and removed from the holder, for renewal or otherwise, and when not in use the point of the marking material is protected by the holder. The holder above described is also applicable for holding pens, knives, toothpicks, and other articles in a somewhat similar manner. The invention consists, second, in the manufacture of holders for lead and other marking materials, whereby a cheap and effective ever-pointed pencil or marking instrument is obtained.—Patent completed.

3016 R. M. LETCHFORD. *An improvement in the manufacture of matches.* Dated October 26, 1867.

This invention consists in saturating match-wood in a solution of resin, previously to dipping the wood in the usual lighting composition.—Patent completed.

3017 W. R. LAKE. *An improved level.* (A communication.) Dated October 26, 1867.

This invention relates to the construction of an apparatus in which the surface-line of a liquid enclosed within a hollow disc of glass, or partly of glass, indicates upon a graduated circle or scale the angle or inclination of any surface upon which the apparatus is placed.—Patent abandoned.

3018 L. NEWTON and T. KERSHAW. *Improvements in bottles, in corks or stoppers for bottles, and in machinery for making corks or stoppers.* Dated October 26, 1867.

One feature of this invention consists in making the bottles with an eye at the top of the neck of the bottle, this eye forming the outlet from the bottle, and being at a right angle to the axis thereof.—Patent abandoned.

3019 F. M. SMITH. *Improvements in the manufacture of armour plates.* Dated October 26, 1867.

The patentee claims the manufacture of armour-plates from soft bar iron, by forming the bar into a single or double coil, welding such coils together, cutting open longitudinally the cylinder thus obtained, and flattening it out into the form of a plate, substantially as described.—Patent completed.

3020 J. J. PERRY. *Improvements in binding or covering books and other similar articles.* (A communication.) Dated October 26, 1867.

This invention has for its object improvements in binding or covering books and other similar articles, and relates to means whereby such articles are capable of being readily connected or disconnected with their bindings or covers. For this purpose the binding or cover is prepared separately from the book or other similar article, and in each side of the binding or cover a pocket is formed, the opening of which is towards that part of the binding or cover which is intended for the back of the book or other similar article, which is provided with two comparatively rigid flaps or leaves, one of which enters each of the pockets in the binding or covers. Thus, by pushing the said flaps or leaves into the pockets, the book or other similar article is firmly connected with its binding or cover, and yet capable of being readily removed therefrom.—Patent completed.

3021 J. BROOKS. *Improvements in obtaining motive power, and in apparatus employed therein.* Dated October 26, 1867.

This invention consists in applying the motion or power obtained from an endless screw, and a toothed or screw wheel, or from a worm and a worm wheel, as a motive power for driving locomotives, ships, railway and other carriages; for working stationary engines, cranes, and other apparatus, and for use generally where motive power is required, the said power being applied either alone or in conjunction with steam or other power.—Patent abandoned.

3022 C. E. HALL. *Improvements in reaping and mowing machinery.* Dated October 26, 1867.

The novelty of this invention is the employment of a rake or comb placed either above or below the platform, and working before the knives, then passing on to, or behind them, and it can be applied to all back side swathe, or any other existing reaping and mowing machinery. Its chief superiority over all others is that it can cut crops, however twisted and laid, which could not now be cut by and existing machine.—Patent abandoned.

3023 W. KENDALL. *Improvements in locomotive engines.* Dated October 26, 1867.

The object of this invention is to increase the facilities for starting locomotive engines, and also to give an available extra power to ascend inclines when required. For this purpose the patentee uses two outside cylinders working on cranks on the end of the driving axle, which has a single crank in the centre, and one inside the cylinder working on the single crank above mentioned. The reversing gear is so arranged that all three cylinders may be employed for starting, and for ascending inclines, and also for any emergency which may arise requiring extra power; and at other times, when running on a level road, or on favourable gradients, the steam can be shut off from the outside cylinders, so that the locomotive can be worked by the inside cylinder alone, whereby much of the resistance at present due from the blast pipe is saved, and the motive power being concentrated in the centre of the engine, increased stability is obtained. By regulating the "lap" of the valve, small quantities of steam can be admitted to the cylinder or cylinders which are thrown out of work, so as to keep it, or them, lubricated when not required to draw the load.—Patent completed.

3024 J. ASSER. *Improvements in croquet mallets.* Dated October 26, 1867.

According to this invention the inventor proposes to cover the striking faces or ends of the mallets with leather, india-rubber, cork, and gutta-percha, or their compounds. The covering is to be fixed to the mallets by means of any suitable adhesive cement, such as glue, or a cement impervious to water, or fixed by means of pins or other fastenings.—Patent abandoned.

3025 A. M. CLARK. *Improvements in steam generators.* (A communication.) Dated October 26, 1867.

The nature of this invention consists in forming a steam generator of a series of vessels, connected together and having tubes descending therefrom into a fire chamber, and providing each tube with an arrangement which insures an active circulation of water in it, and, at the same time, avoiding such joints as are difficult to make or repair by ordinary labour. The details of the invention are too voluminous to be quoted here.—Patent abandoned.

3026 A. M. CLARK. *Improvements in railway and other brakes.* (A communication.) Dated October 26, 1867.

This invention cannot be described without reference to the drawings.—Patent completed.

3027 W. PAYNE and A. B. FRASER. *Improvements applicable to ships' and other pumps.* Dated October 28, 1867.

This invention consists in certain improvements applicable to ships' and other lift pumps, the heads of the suction pipe or pipes of which open into an enclosed chamber, and the working barrel of which extends down through the top of the enclosed chamber to near the bottom of the vessel, at one side of the suction pipe or pipes, and also consists in dividing the chamber between the suction pipe or pipes, when one or more suction pipes are connected therewith by a vertical diaphragm, the lower portion of which is solid to a point above the lower valve in the working barrel, and above this it is perforated or formed into a grating, through which the water from the suction pipe passes to the working barrel. The object in making the lower portion of the vertical diaphragm solid is to prevent the pump losing its water, thus obviating the necessity of "priming," and the grating of the vertical diaphragm is used to prevent chips or other foreign matters passing into the working barrel and choking the valves. The invention further consists in the use or application of a short open-ended cylinder, which may be screwed to one or both ends, and which cylinder is screwed in, or fastened on, to the head of the suction pipe or pipes entering the enclosed chamber.—Patent completed.

3028 J. DE SILVA. *Improved compositions for coating the bottoms of iron, steel, and wooden ships, and other navigable vessels and marine works generally.* Dated October 28, 1867.

The patentee claims applying to the bottoms of iron and steel ships a coating formed of the following ingredients, namely:—Bridgwater paint (a fireproof paint, a mineral found in America, resembling oxide of iron), pure zinc, pure white lead, and strychnine, ground in boiled oil to a stiff consistency, arsenic, and lobelia inflata. These ingredients are combined in about equal proportions, except the arsenic, which is in excess to the proportion to the lobelia inflata. To the several materials is added chiefly bright varnish and tar oil, and, when required, a little spirit of genuine turpentine. The whole of these ingredients are thoroughly amalgamated, and are applied to the bottoms of the vessels to be coated, either in a hot or cold state, by a brush, in the same way as ordinary paint.—Patent completed.

3030 H. A. BONNEVILLE. *A new and improved machine for manufacturing paper sacks.* (A communication.) Dated October 28, 1867.

The principle of the invention consists in the continuity and simultaneousness of the different operations, and in the adherence arising from the use of an endless caoutchouc feed cloth, which carries along with it the paper with which the bags are manufactured.—Patent completed.

3031 W. E. DE BOURRAU. *Improvements in evaporators for concentrating saccharine fluids.* Dated October 28, 1867.

This invention consists of a rotating apparatus for concentrating saccharine fluids by means of steam, some of the principal advantages of which are as follows:—First as steam is the only heat employed, there is no risk of burning or discolouration. Second, economy, as the waste steam from the cane mill will suffice for the purpose. Thirdly, quickness of evaporation, owing to the constant rotation; and, fourthly, saving of labour, as when the apparatus is once set in motion it requires no further attention, and, if left a sufficient length of time, will evaporate the syrup to dryness. The apparatus consists, mainly, of a basin or open vessel to receive the syrup, and a rotating evaporator composed of four cupolas (forming two hollow dome-shaped ends) connected together by about twenty-eight tubes near the circumference, six intermediate tubes of the same diameter, and a master tube of a large size in the centre at each extremity of the tubes (which lie horizontally); two of the cupolas form a hollow dome-shaped chamber containing two funnels for collecting the water of condensation, and in one is a distributor of the steam as it enters through the hollow axes, all being made of copper. A ring of copper surrounding the central tube is provided with four (or more) arms, connected to a circle of about the diameter of the evaporator, and being placed midway between the two ends serves to give solidity to the apparatus. The basin or open vessel is supported on suitable wooden or metal frames, one at each end, and also one under the centre of the same. The end framings also support in suitable bearings the hollow axes through which the steam passes, and the necessary spur or other gearing for giving rotary motion to the evaporator.—Patent completed.

3032 J. YOUNG. *Improvements in the application of cannel coal slack to the manufacture of gas and coke.* Dated October 28, 1867.

The patentee claims, first, the application, preparation, and treatment, of cannel coal slack, by crushing, washing out the impurities, warming, drying, and combining with hydrocarbons as described, for the manufacture of illuminating gas and coke. Second, the compression of the purified cannel slack into blocks adapted for transport as a substitute for coal in making coke, and for other purposes, for which processes any ordinary and suitable mechanical means may be employed, no claim being made herein for the mechanism used.—Patent completed.

3033 C. E. BROOMAN. *Improvements in the manufacture of lace.* (A communication.) Dated October 28, 1867.

The patentee claims, first, the system or mode of numbering the running threads, by the aid of which system the warp threads intertwine while maintaining their twists; and, secondly, the arrangements of the bars which permit of realizing this numbering, with the view of manufacturing the lace called "Paris point," substantially as described.—Patent completed.

3034 A. J., W. B. and S. H. WATERLOW. *Improvements in machines for printing from copper, steel, and other metal plates, applicable also for printing from lithographic stones.* Dated October 28, 1867.

The patentee claims, first, the construction and use of machines for steel, copper, and other plate printing in which the printing surface is carried at one side or end of a box or frame, made to rotate or revolve along with a shaft, which shaft carries also a large tooth wheel operating through other tooth wheels, levers, and the other component (moving) parts of the machine; and, second, the peculiar conformation of that side or end of the box or frame which is opposite to the side or end carrying the plate or printing surface, by which, in conjunction with rollers on bed-plate, a gradual alternate up-and-down motion is imparted to the box or frame, so that the plate or printing surface is kept in uniform contact with, and with equal pressure against the printing cylinder during the operation of printing. Third, the slots or guides in the box or frame admitting of this motion, and the stops for preventing such motion taking place excepting at the proper time, all as described.—Patent completed.

3035 J. GLOVER. *Improvements in furnaces for steam boilers and other uses.* Dated October 28, 1867.

The patentee claims forming furnaces for steam boiler and other uses with bars having openings and blank spaces, alternating in the direction of their length, in manner substantially as explained. And, second, he claims the applying raised ribs next the sides of the flue, or of the furnaces, as described.—Patent completed.

3036 M. HENRY. *Improvements in balloons, and in apparatus employed in connection therewith.* (A communication.) Dated October 28, 1867.

This invention is not described apart from the drawings. —Patent completed.

3037 T. BENNETT. *Improvements in the manufacture of spoons, forks, and ladles.* Dated October 28, 1867.

The patentee claims producing, by rolling upon one or both sides of hoop iron at the required distances apart, several solid beads, ribs, or thickened parts, or producing, by rolling a continuous solid bead or rib on one side, and several solid beads or ribs at the required distances apart on the other side of the hoop iron, substantially as described and illustrated, which said solid beads or ribs or thickened parts, when the hoop iron is manufactured into spoons, forks, and ladles, give great strength to the handles of the said spoons, forks, and ladles. Also making the bead or rib by which the handle of the spoon, fork, or ladle is strengthened, separately from the blank, and fixing it in the blank, substantially as described and illustrated.—Patent completed.

3038 W. POTTS. *Improvements in making moulds for the manufacture of metallic screws.* Dated October 28, 1867.

This invention consists in making the moulds by first moulding a plain cylindrical mould of the required size, with or without a head, and afterwards moulding the screw threads in the interior of the plain cylindrical mould, by screwing a pattern screw through the said mould.—Patent completed.

3039 H. G. P. MEADE. *Improvements in firearms and ordnance, and in projectiles therefor.* Dated October 28, 1867.

According to this invention the inventor constructs a gun of a cylindrical form, both internally and externally; it is closed at the breech end, and has a capacity, little, if at all, exceeding that required to receive the largest charge the gun is required to carry. The projectile is also cylindrical internally, and adapted to fit over the gun; it is closed at the fore end, which is made of a suitable form for flight, and also for penetration; it may contain a bursting charge, and be fitted with a fuse if desired. The gun at its breech end is fixed in a trunnion piece formed to bring the trunnions so far forward that the weight of the breech end of the gun may preponderate, even when it has received the charge and the projectile. An elevat-

Digitized by Google

ing screw, or other elevating gear, is fitted at the breech end of the gun. The trunnions are carried on a carriage, so arranged as to admit of the gun being trained. The muzzle of the gun, and the interior of the projectile, are mutually so shaped that the strain resulting from the explosion of the charge may not operate against the sides of the projectile until the projectile has acquired a considerable forward velocity; this may be effected by coning the muzzle of the gun on the exterior, and forming the projectile to fit closely to the mouth of the bore. The fore end of the bore may also be coned interiorally, so as to increase the area at the base of the projectile, on which the pressure resulting from the explosion of the charge is able to act, to start the projectile into motion. When a reduced charge is used with the gun, a wad or filling piece of suitable material may be introduced into the bore temporarily, to reduce its capacity. It is not essential that the gun should be cylindrical; it may be polygonal, or of other form exteriorly. The form of the bore may also be varied. In mortars or pieces to throw heavy shells, the inventor makes the bore of the piece of smaller capacity than is required to contain the charge; a portion of the charge is then contained within the cavity of the projectile. In order that the charge may be effectually consumed before the projectile leaves the gun, he may employ more than one vent; sometimes, in addition to the breech vent, he forms a vent, passing both through the side of the projectile, and through the gun, and he also forms a vent passing through the head of the projectile in advance of the muzzle of the gun. In some cases he employs well-known arrangements within the cartridge, and fires it from end to end. To give a rotary motion to the projectile, lands or grooves may be formed within it, there being also corresponding lands or grooves formed on the exterior of the gun.—Patent abandoned.

3040 V. V. DE CRESALLES. *Improvements in apparatus for obtaining power from rivers or streams of water, and for facilitating boats ascending and descending rivers or streams.* (A communication.) Dated October 28, 1867.

In constructing apparatus for obtaining motive power from rivers or streams of water, two parallel endless chains are employed, extended between, and gearing with chain wheels on two horizontal axes, at a distance apart from one another. The endless chains are connected to one another by numerous rods or bars, which pass transversely across the space between the two chains. These rods carry paddles or floats, which project out at right angles from the chains. The axes of the chain wheels supporting the chains are carried at such a distance above the surface of the water that the paddles or floats on the portion of the chain, below the chain wheels, dip into, or are immersed in the water, whilst the paddles on the portion of the chain above the chain wheels are raised out therefrom. The axes of the rollers turn in bearings carried by vessels, held at a distance apart from one another by suitable frames and tie bars, so that the endless chain of paddles work in the space between the vessels, or the axes of the endless chains might be otherwise carried. The fixed guide rails are employed to keep the endless chains from sagging or swaying down as they pass from one chain wheel to another; small flanged rollers carried on the ends of the transverse rods connecting the two chains run upon these rails, and thus the chains are supported. As the action of the stream of water upon the paddles or wings of the endless chains gives to these chains a continuous rotary motion, the chains, by gearing with the chain wheels, cause the axes of these wheels to revolve also. Motion may be transmitted from these axes to pumps carried by the vessels, and may then be used for irrigating purposes, or the power obtained may be employed to enable boats to ascend the stream, or it may be applied to other purposes.—Patent abandoned.

3042 E. B. WILSON. *Improvements in furnaces.* Dated October 29, 1867.

This invention is not described apart from the drawings.—Patent completed.

3043 G. W. B. EDWARDS. *Improvements in machines for dibbling and dropping seed and corn.* Dated October 29, 1867.

This invention has for its object the dibbling of holes in the land at regulated distances apart, and depositing the seed or corn therein by means of the machine hereinafter described. The machine for this purpose consists essentially of one or more dibbling instruments, constructed as hereinafter described, adapted to work in combination with a seed barrel, or barrels, in which the several cups are successively turned, so as to let the seed brought up from the seed box drop into a channel immediately over the hole made by the dibble. The dibble is of about the same form as the ordinary iron hand dibble, and has on its stem a screw or spiral, which works through a corresponding internal screw or worm fixed in a frame, by which means the dibble, on being moved vertically, has imparted to it a slightly revolving motion, similar to that given to the ordinary dibble by hand, for the purpose of making a clean and smooth hole. The dibble, or set of dibbles, may be worked up and down as required by a crank or otherwise, a spring being applied to the dibble if required, in order to give it elasticity in working. The seed barrel is furnished with cups fixed in the disc at equal distances apart, having their pivots passing through the disc, and being acted upon so as to give them a partial turn as they arrive in succession over the channel, immediately over the holes made by the dibble.—Patent abandoned.

3044 J. SMYTH and S. KIRBY. *Improvements in clarionets, flutes, bassoons, saxophones, sarrusophones, and other keyed wind musical instruments.* Dated October 29, 1867.

This invention consists of, first, a new double movement key with two levers or handles, one over the other, opening lengthways, and stopping or unstopping but one hole; the object of the double lever is to permit the action that raises the whole key and unstops the hole, viz., the ring over the third finger hole of the left-hand joint of the clarionet can be used without opening the double lever key, unless at the free option of the performer, and at the precise time and instant it is wanting, to produce the notes G sharp, D, and any others, on the upper or lower joint, thus giving those notes from new positions, with an entirely new description of key, and with a facility never hitherto obtained on the clarionet, flute, bassoon, and similar instruments. This key with two levers can be applied to any part of the clarionet, or to any kind of instrument upon which keys are used, for unstopping holes, or stopping open holes, for the production of notes or sounds. Second, single movement keys to the clarionets, to produce and perfect the notes on the upper or left-hand joints, such as F natural, F sharp, and others, without the use of the right hand to the keys on the left-hand joints. Third, new single movement keys to clarionets, for new fingering of notes, E flat, and others on right hand. Fourth, new single movement keys to clarionets for C sharp, low F sharp, and others on right-hand joint. Fifth, new single movement keys to clarionet for B natural, low E natural and others on the right-hand joint; and, sixth, new double movement key, the same as on the upper joint, for making D sharp with the first finger of the right hand on lower joint, and G sharp on upper joint.—Patent completed.

3045 E. T. HUGHES. *Improvements in machines for twisting lines, cords, ropes, and cables, and hanking and coiling the same.* (A communication.) Dated October 29, 1867.

This invention is not described apart from the drawings.—Patent completed.

3046 J. T. CARTER. *Improvements in the manufacture of circular webbing or gasket, applicable as packing for steam engines, as covering for telegraph cables, and other useful purposes, and in the machinery employed therein.* Dated October 29, 1867.

This invention consists in manufacturing circular webbing or gasket from several strands of hemp, wire, or other material which are secured to each other to form one circular piece, by means of one or more wires, threads, or cords, which are passed over one strand, under another, over the third, and so on continuously. The webbing or gasket may have a central core, or not, according to the purpose for which it is intended.—Patent abandoned.

3047 W. BISHOP and B. BURNINGHAM. *Improvements in apparatus for preventing effluvia entering tanks or cisterns from the waste pipe.* Dated October 29, 1867.

This invention relates to a means of preventing the admission of effluvia from drains entering cisterns by the waste pipe, as is commonly the case, and consists in the application of a lift-valve fitting in a socket let into the bottom of the cistern or tank, which socket communicates with a pipe for carrying away the surplus water to the closet or drain. The valve stem passes up through a bridge-piece and guide attached to the socket, a tube being fixed on the neck of this guide, supporting a float at the height to which the water is to rise. This float is connected to the valve stem by means of a rod or chain passing down through the said tube, the length of the rod or chain being regulated as desired by means of a nut and screw passing through the float.—Patent completed.

3048 J. H. JOHNSON. *Improvements in cleaning cotton and cotton seeds, and in the machinery or apparatus employed therein.* (A communication.) Dated October 29, 1867.

In carrying out this invention the cotton in the state in which it has been picked or gathered, viz., whilst still enclosed in the pod, is thrown into a receptacle provided with a discharging hopper which discharges the cotton pods into a wire, gauze, or perforated metal cylinder, along the interior of which there is disposed a rotatory shaft or spindle, carrying a number of blades or arms arranged in a heleodical manner along the surface of the same. On imparting a rotatory motion to this spindle by means of a strap and driving pulley, or otherwise, the cotton will be freed from the pods, which will fall through the cylinder on to an inclined spout, and be thereby discharged into a basket or other convenient receptacle, if desired. The cotton itself will be urged along the cylinder by the spiral rotatory blades, and will be discharged at the end thereof on to the inclined floor or surface of a chamber which is provided with a spiked or pegged roller, such roller reaching nearly in contact with the inclined floor, which latter at the part nearest to the roller is also provided with spikes or pegs, between which those on the roller pass when rotating. The action of the revolving spiked roller and stationary spiked surface is to disintegrate or open out the cotton, and remove therefrom any remaining portions of pods, husks, or other like extraneous substances still adhering to the cotton. After passing under the action of the spiked roller, the cotton enters another wire, gauze, or perforated metal cylinder, provided like the first with a revolving spindle and heleodical arms or blades, which finally act upon the cotton before it is collected in baskets or other receptacles. At this stage the cotton is freed from the cotton seeds which are still contained therein by any well-known or suitable arrangement of cotton gin, after which the cotton is ready for manufacturing purposes.—Patent abandoned.

3049 W. P. SAVAGE. *Improvements in machinery for excavating, raising, and depositing soil.* Dated October 29, 1867.

The patentee claims, first, the arranging a machine for excavating, raising, and depositing soil, with the endless chains of buckets to cut in advance of the travelling wheels at the sides of the machine. Second, the arranging a machine for excavating, raising, and depositing soil, substantially in the manner described. Third, the arranging a machine for excavating, raising, and depositing soil, with a central chain or chains of buckets, working in advance of the carrying wheels, and between them, and also other endless chains of buckets on either side, working in front of the travelling wheels. Fourth, the arranging a machine for excavating, raising, and depositing soil, substantially in the manner described. Fifth, the arranging a machine for excavating, raising, and depositing soil, and adapted especially for cutting trenches, with a chain of buckets working in advance of the travelling wheels, but between them.—Patent completed.

3050 L. PERKINS. *Improvements in water and other meters, and in engines for obtaining motive power.* Dated October 29, 1867.

According to this invention the use of tappets or cams acted on by the piston or piston rod is dispensed with, and the admission of steam or fluid to the cylinders which work the valve or valves of the engine or meter, or it might be the putting these cylinders in communication with the exhaust, is governed by a valve moving reciprocally with the piston of the engine—that is, that it shall both commence and end its stroke simultaneously therewith; it may either be that the piston itself is made to form the valve, or an independent valve making an equal stroke with the piston, or a stroke of any other desired length may be employed. The details of this invention are too voluminous to be quoted here.—Patent completed.

3051 G. DAVIES. *An improved mode of preventing incrustation in, and removing it from, steam boilers.* (A communication.) Dated October 30, 1867.

The patentee claims the application to steam boilers of hydrocarbons, either alone or in combination with other materials, for the purpose specified.—Patent completed.

3052 W. H. A. BOWHAY. *Improvements in the construction of horse ploughs* Dated October 30, 1867.

The patentee claims, first, the placing a wheel or wheels within the body of double or one-way ploughs, so as to destroy the balance of the plough, and keep the hinder share free from the ground, by means of the combination and arrangement of parts and mechanism, substantially as described. Second, the construction and arrangement of two simple bodies within one main longitudinal beam, the one right and the other left hand, substantially as described. And, third, the use of a wheel in the construction of single ploughs for the purpose of lightening the draught, and for varying the pitch or inclination of the share, substantially as described.—Patent completed.

3053 J. FEATHER. *Improvements in, or applicable to, cap frames employed in spinning worsted or other fibrous substances.* Dated October 30, 1867.

This invention relates to that class of spinning machinery technically known as "cap frames," and the improvements consist in the application of a small flyer, mounted, and capable of rotating on a pin at the top of each cap. The yarn to be spun is caused to pass through a tweezle in one arm of this flyer in its passage to the bobbin, by which the flyer is driven or carried around, and thereby a drag is put upon the yarn. By this invention the inventor is enabled to spin on cap frames, "lustre yarns," or yarns which hitherto could not be spun on cap frames.—Patent abandoned.

3054 J. MADDOCKS. *Improvements in the method of, and apparatus for, securing nuts and bolts employed on the permanent way of railways.* Dated October 30, 1867.

This invention is designed for the purpose of preventing the nuts used to secure fish-plate joints on railways from turning, and becoming unscrewed by the vibration of the rails caused by traffic. The improvements consist in the employment and use of a metallic plate, the lower side of which is straight and level, excepting a projecting piece occupying a relative position to one of the middle nuts, and the end of the plate near this projection is turned round so as to overlap it, and in this projecting piece a hole or vertical slot is formed. In making the joint, the first, third, and fourth bolts are to be passed through the "fish plates" and rail, and the nuts screwed thereon, each nut having one flat side uppermost. The lower edge of the metallic plate is then laid on the three flat surfaces of the nuts, which brings the slot or hole in the projecting piece over the second bolt, and the second bolt is passed through the fish-plate rail and the metallic plate, and the nut screwed on, which locks the first, third, and fourth nuts, and prevents them turning; the turned end of the plate is now so adjusted or bent as to overlap the flat surface of the second nut, which is thereby also prevented from turning. When required to unscrew the nuts, the overlapping end is sprung back or forced outwards, and the nut is liberated for the action of the wrench—Patent completed.

3055 J. B. FENBY. *Improvements in valves for hydraulic presses and for other purposes.* Dated October 30, 1867.

The patentee claims constructing the valves of a hollow cylinder, and a piston or plunger working therein, the said hollow cylinder and piston or plunger, and parts connected therewith, being constructed and arranged substantially as described, whether the valve be worked by the direct motion of the piston or plunger, or by a small supplementary valve of similar construction.—Patent completed.

3056 T. E. SYMONDS. *Improvements in the construction of ships and other vessels.* Dated October 30, 1867.

In ships and vessels propelled by two screws at the stern, one on either side of the stern, a system of propulsion, now well known as the "twin screw system," the portions of the screw shaft which are exterior to the ship or vessel are usually enclosed in trunks or tubes, the after extremities of which have been hitherto supported and attached to the bottom and dead wood of the ship or vessel by V or bracket frames carrying the bearings for the screw shafts. To give additional support to these trunks or tubes, and to the bearings of the screws which they contain, so as to promote the rigidity of the structure, and lessen vibration in single-keeled ships, the patentee fixes a strong web or plate, or gusset piece, to the trunk or tube from end to end, passing up until it meets the bottom of the ship, at an angle of about 45deg., or somewhere thereabout, with the vertical plane of the ship or vessel, or, in other words, he causes the web plate, or gusset piece, to pass in the shortest manner possible to the bottom. The second part of the invention consists in capping the outer end of the trunk with a metal cap serving to retain the outer ends of the planking or sheathing, and also to have an overlapping flange to cover or close the space or joint between the boss of the propeller and the bearing, so as to prevent objects being drawn in to stop or interfere with the action of the propeller. The fore side of the boss of the propeller should be so formed as to facilitate the object of the invention, and the overlapping flange may either be formed with the cap, or separately, and fixed to it by screws or otherwise.—Patent completed.

3057 F. PIERCY. *Improvements in the method of tinting or colouring photographs, engravings, water-colour and other drawings, or porcelain.* Dated October 30, 1867.

The patentee claims, first, tinting or colouring photographs, engravings, water-colour, and other drawings, or porcelain, by the several means and processes described. Second, he claims the use in the above processes of an intervening material or materials upon which is to be transferred by means of pressure, rubbing, and burnishing portions of colour not required in the finished work of art, as and for the purposes described. Third, he also claims obtaining an entirely novel effect in the process of tinting or colouring, by the employment of bread in the manner and for the purposes described.—Patent completed.

3058 J. H. JOHNSON. *Improvements in racks or holders for whips, canes, and other like articles.* (A communication.) Dated October 30, 1867.

This invention relates to racks for holding whips and other like articles, and consists, mainly, in the combination with a skeleton or perforated frame of wood, or other suitable material, of an elastic binding or holding device, arranged in the perforations of the said frame, in such manner as to hold any object placed or inserted in the perforated frame.—Patent abandoned.

3059 EARL OF CAITHNESS. *An improved mode of, and apparatus for, cleaning boiler tubes.* Dated October 30, 1867.

This invention consists in the employment of one, two, or more long screw spindles, which are temporarily introduced through holes made for that purpose in the tube-

Digitized by Google

plate next to the smoke-box. These screw spindles, when introduced into the boiler, engage with one or more tube-cleaners inside the boiler, each consisting of a perforated plate through the perforations in which the tubes are passed when being secured into the boiler. The holes in the cleaners are sufficiently large to allow the cleaners to traverse freely along the tubes from end to end, for the purpose of removing any deposit therefrom.—Patent abandoned.

3060 A. V. NEWTON. *Improvements in the ventilation of buildings, ships, and carriages.* (A communication.) Dated October 30, 1867.

This invention relates to a mode of supplying fresh air to apartments, and to compartments of carriages, and withdrawing or discharging the vitiated air therefrom without producing drafts. In applying the invention to buildings, say, for example, to a hospital, which requires specially good ventilation, the internal walls are built hollow, that is, with vertical air passage in them. The portion of the wall between the air passages and the chamber or ward to be ventilated is built of bricks pierced with holes, which, as the bricks are laid, form small horizontal air channels for the air supplied to the vertical air passages. The passages are divided horizontally, at a height of, say, five or six feet from the floor, and distinct air flues connect with the upper and lower divisions thus formed, the larger or upper division being used for supplying cold, and the smaller and lower division for supplying heated air to the ward or chamber. The wall is faced with porous cement, which allows the air at a pressure to percolate through, in minutely divided streams, into the chamber, after the manner of tent ventilation. The roof of the chamber is also porous, and it forms between the girders, which may be of iron, air exhaust flues. Below the floor of the chamber, or ward above, are also air flues, separated from the lower flues by substantial laths enveloped with some material that is a good non-conductor of sound. These flues are connected with vertical exhaust flues built in the walls, and connected with a chimney shaft, or an exhaust fan, to quicken the withdrawal of the vitiated air.—Patent completed.

3061 C. and J. JOBSON. *Improvements in screw propellers.* Dated October 31, 1867.

This invention consists in increasing the length of the boss or axis on which the propelling blades are fixed, and arranging the blades on different parts of its length and circumference in such a manner that in cross section each part of the boss forms a separate propeller with a single blade.—Patent completed.

3062 R. CLEGG. *Improvements in the construction of pumps.* Dated October 31, 1867.

This invention consists in the employment of a cam or eccentric wheel working on an axis within a cage or frame in the interior of the body of the pump. At the lower or bottom end of this cage or frame is the piston. One revolution of the axis causes the piston to be raised and lowered three times. The cam or eccentric wheel has three projecting points, which press against small friction rollers at the top and bottom of the cage or frame, thus causing the piston to be raised or lowered for the suction and delivery of water or other liquid. The axis passes through the body of the pump, to one end of which is attached a crank and handle.—Patent completed.

3063 W. HALL, J. WREN, and J. BRANDWOOD. *Certain improvements in the method of casting, forming, or producing toothed wheels or gearing to be employed in machinery for preparing, spinning, and twisting cotton or other fibrous substances.* Dated October 31, 1867.

This invention relates to such wheels or gearing as are required to be made in halves, or two parts, in order that they may be secured upon any shaft without removing the shaft or other gearing therefrom. The improvements consist in casting the toothed wheels or other gearing in one piece having a hollow mid-feather, or double flange, with a slot or opening left between them, extending at the back from the boss to near the periphery. When the wheel is furnished in the lathe, a tapered wedge is inserted in the boring for the shaft, which, being sharply struck with a hammer, causes the casting to break through the boss, and the ends or junction of the mid-feather, and the periphery, which is the weakest part, and the wheel is thus broken into halves, leaving the uneven granulations of the metal as a fitting surface. When the wheel is to be secured on a shaft, the halves are placed one on each side, so that the boss encircles the shaft, and screw bolts or screws are passed through holes in the sides of the mid-feather or flanges, and the two halves are thus secured together, the fractured parts fitting so closely that the junction is scarcely perceptible, and the true pitch of the wheel is retained.—Patent completed.

3064 W. S. DIXON. *A new process of producing a blue dye or colouring matter.* Dated October 31, 1867.

In the lower carbonaceous stratification of the counties of Midlothian, Linlithgow, and Lanark, in Scotland, and elsewhere, and in working what is called slaty band, ironstone there is found, and thrown out, as waste, and exposed in heaps, a certain mineral or substance, commonly called in such counties "Maggie," from which heaps, and by the action of rain and atmospheric influence thereon, there proceeds or flows a reddish liquid, which contains more or less of the following:—Sulphate of ammonium, 873.01 grains per gallon; sulphate of iron (proto), 484.22 grains per gallon; sulphate of iron (per), 374.10 grains per gallon; sulphate of lime, 73.27 grains per gallon; sulphate of magnesia, 74.22 grains per gallon; chloride of sodium, 3,37 grains per gallon. Suspended matter:—Carbonaceous matter, 2.13 grains per gallon; carbonate of iron, 8.93 grains per gallon. Total, 5261.25 grains per gallon. This invention consists in the employment of a process of treating the above-mentioned reddish liquid by mixing therewith a saturated solution of yellow prussiate of potash, or its equivalent, and obtaining a dye, or blue colouring matter, which may be used for various purposes.—Patent completed.

3065 E. DONNER. *An improved method for clearing skins destined for hatters' furs from the coarse hair (kemp, bristles, or sleekcoats), by combustion.* Dated October 31, 1867.

This invention consists of a method for clearing skins from the coarse hairs (hemp bristles or sleekcoats), by a process of calcination or combustion. In order to perform this operation the skin is first carded and rendered flexible by moisture, then suspended by a hook upon a plane surface, inclined at an angle of 75deg., or any other suitable angle, that part of the skin corresponding to the tail of the animal being uppermost, so that the hairs on the skin have a tendency to stand erect by their own weight. The inclined plane should be placed before the operator, who combs the hairs from the tail towards the head, that is, from the highest part of the inclined plane, towards the lowest, thereby causing the said hairs to stand comple ely on end; the operator then applies a flame to the ends of the coarse hairs, which partly calcines them, after which he combs away the singed hairs, and applies the flame to those bristles that have not yet been removed. These two operations are continued, one after the other, till the whole of the coarse hairs are burnt away, and nothing is left on the skin but the down.—Patent completed.

3066 J. T. CAIRD and S. ROBERTSON. *Improvements in transmitting motive power, and in mechanism or apparatus employed therefor.* Dated October 31, 1867.

This invention is not described apart from the drawings. —Patent completed.

3067 O. C. EVANS. *Improvements in digging machinery.* Dated October 31, 1867.

This invention has reference to a previous patent granted to the present patentee, dated April 22, 1865 (No. 1124), and consists, first, in an improved method of arranging one or a series of endless chains, carried by a suitable framework, so that they can be caused to revolve or roll over the surface of the ground. These chains have teeth or digging forks attached to them as well as being so arranged on drum wheels and rollers that they will form an angle or inclined plane as they approach the ground, but will rise from the ground at a much more abrupt angle. The effect of this arrangement will be to cause the teeth or digging forks attached to the chains to enter the ground in nearly a vertical position, and again to turn at so short an angle as will suddenly lift the teeth or digging forks backward, upward, and out of the ground with force enough to upheave the soil. The invention is not fully described without reference to the drawings.—Patent completed.

3068 W. R. LAKE. *An improved cap for upholstery or furniture springs.* (A communication.) Dated October 31, 1867.

According to this invention the inventor prefers to construct his improved cap by stamping or pressing the same with suitable implements from sheets of iron, brass, tin, or other metal, but the same may be formed of cast metal. The said cap is constructed in a circular form, and has four long arms with eyes or holes in the ends thereof, so arranged as to connect easily with other caps used in the same frame, and with the sides of the said frame. The long arms are also extended to afford additional support to the mattress or other article of upholstery placed thereon.—Patent abandoned.

3069 W. R. LAKE. *An improved mode of, and apparatus for, exhausting or rarefying the air in vessels for food preserving, distilling, and other purposes.* (A communication.) Dated October 31, 1867.

This invention relates to a novel method of removing the air from vessels or receptacles for preserving food, and for distilling and other purposes, and consists, chiefly, in producing a vacuum, or partial vacuum, in a space above the surface of a body of water, enclosed in a cistern, which space is placed in a communication with the vessel or receptacle to be exhausted through an exhausting apparatus. It is well known to all who are familiar with the subject, that the proportion of air held by absorption in water has heretofore prevented the formation of a perfect vacuum by the use of water in what is known as the "Torricellian" process. In practising this invention the patentee uses apparatus in which certain parts are so proportioned and arranged that the air in a body of water is first separated from the water, which is afterwards used for producing a vacuum in other portions of the apparatus. The said apparatus is provided with a suitable arrangement of valves, whereby it is first filled with water from the cistern, then emptied through a pipe of such a length that the column of water contained therein will overcome the external pressure of the atmosphere. Air is then admitted from the vessel to be exhausted. The communication between the exhauster and the said vessel is then closed, and that between the exhauster and cistern opened. The air in the exhauster is displaced by the descending water, and ascends to the space at the top of the cistern, the operations being repeated till the desired vacuum is created in the vessel or receptacle. Where a sufficient height cannot be obtained, the exhauster may be emptied by the aid of an air chamber and pump.—Patent completed.

3070 I. KENDRICK. *Improvements in steam boilers.* Dated October 31, 1867.

This invention mainly consists in certain improved arrangements of water chambers or spaces (which the patentee calls circulating generators), in the flues or tubes of Cornish and other boilers, whereby the flame and products of combustion, or some of them, are caused to take a serpentine course, or from side to side, and up and down manner, in their passage from the furnace to the chimney. The patentee's circulating generators are preferably made with flat sides, and with a round tube, the top and bottom of suitable size to connect them to the tubes or flues of the boiler. The top and bottom connecting tubes may be flanged and riveted to the tubes or flues, but to facilitate their application or their removal in case of repairs being required, he prefers to connect them by the well-known method of expanding without flanges. These circulating generators, when for the flues or tubes of Cornish boilers, he makes of a semicircular form and flat-sided, or they may be made of any analogous form, and flat-sided to suit the flue or tube in which they are fitted.—Patent completed.

3071 J. WATKINS. *Improvements in axles for carriages.* Dated October 31, 1867.

The patentee claims, first, making the bed of the axle without the usual fixed solid collar, and the axle box without the usual reservoir in its head, and connecting the axle box to a loose collar or revolver on the cone of the arm, the said loose collar or revolver being secured in its place upon the cone by means of a screw lock, nut, or screw collar, the said loose collar or revolver and screw lock, nut, or screw collar being constructed and arranged or combined substantially as described.—Patent completed.

3072 A. CHAPLIN. *An improved portable distilling apparatus for producing fresh aerated water from sea water, part of which said apparatus is also applicable to the burning of hydrocarbon oils for other purposes.* Dated October 31, 1867.

This invention consists, mainly, of a steam boiler in combination with a condenser, tank feed chest, hand pump, and certain arrangements of pipes and cocks which render the apparatus self-acting, or nearly so, requiring only occasional attentions from the person in charge. The details of the invention are too voluminous to be quoted here.—Patent completed.

3073 D. SYKES. *Improvements in machinery or apparatus for decorticating, hulling, or husking pearl barley or other similar grain.* Dated October 31, 1867.

This invention consists in the employment and use of two cylinders, one enclosed within the other, having an annular space left between their surfaces, both cylinders being mounted on one common centre or shaft, the internal solid cylinder being keyed or secured to such shaft, and the outer hollow cylinder running loose on the same. The periphery and sides of the internal cylinder are composed of steel plates, having a burred or serrated surface, the outer cylinder being perforated. The annular space left between the surfaces of the cylinder is for the purpose of receiving the grain to be operated upon, which is fed thereto through a hopper or funnel, conveniently placed at the side. When the mill is in action, the internal serrated cylinder is driven at a higher velocity than the outer cylinder, by an arrangement of internal gearing or other equivalent, both cylinders being caused to revolve in the same direction. The grain, by this means, being constantly under agitation, the rubbing or bruising action, which effectually and thoroughly decorticates the grain, the husks or chaff being constantly expelled on becoming released from the grain through the perforations in the outer cylinder.—Patent abandoned.

3074 F. TEW. *Improvements in drawer suspenders and brace fastenings.* Dated October 31, 1867.

This invention consists in combining a suspender for the drawers with an ordinary brace buckle. This suspender consists of a strap of leather, webbing, or other material, provided with buttonholes, or other means of attachment to the drawers, which strap may be attached to the brace buckle in any convenient manner.—Patent abandoned.

3075 [illegible] B. RODEN. *Improvements in breech-loading firearms.* Dated November 1, 1867.

This invention relates to the construction of breech-loading firearms using self-ignition cartridges, and consists of a combination of parts constituting an improved mode of construction, whereby increased safety and security against accidents, and also a more efficient and ready mode of ejecting the expended cartridge case, are attained. The details of the invention are too voluminous to be quoted here.—Patent completed.

3076 J. STURGEON. *Improvements in machinery employed in getting coal, stone, and other minerals, and in apparatus connected therewith.* Dated November 1, 1867.

This invention has reference to a previous patent granted to the present patentee, dated July 2, 1867, (No. 1927), and relates, first, to an improved system of "opening out," or driving headings in coal and other mines by means of machinery worked by compressed air or other fluid. In "opening out" or driving headings, it is usual, first, to undercut or "hole" a certain portion of the work for the required width of road, and to cut nicks vertically at each end of the undercut portion, in order to break away and remove the material. This improvement consists in so arranging the machinery for cutting the said "nicks" so as to give them a curvilinear or arched direction upwards, instead of cutting them in a straight perpendicular line. By this means, when the material is broken out as above stated, the sides of the drift or cutting will be left of an arched form, thereby affording a better support to the roof than if the sides were left perpendicular to the base or floor of the mine.—Patent completed.

3077 H. and G. S. HUNTER. *Improvements in the construction of hats and caps.* Dated November 1, 1867.

According to this invention the inventors place between the body of a hat or cap, and its lining, a series of small tubes, or they coil, or lay in one long length of tube, made of elastic, gum, oiled silk, or other elastic or flexible material. These tubes, or the coil of tube, are made of a circular oval, square, or other form in section, and are either closed at the ends to prevent the air in them from escaping, or are left open to allow the air to leave and enter when the hat or cap is in use.—Patent abandoned.

3078 G. HAYCRAFT. *Improvements in apparatus for filling flasks, canisters, and other receptacles with gunpowder.* Dated November 1, 1867.

For the purpose of this invention, the inventor employs a circular stand, capable of holding a number of flasks, canisters, or receptacles; the circular stand is supported by, and capable of revolving around a fixed central pivot (by preference, of brass), projecting up from a table or bench. The revolving stand is composed of a wooden spindle, carrying two discs, one at its upper end, and the other at its lower end. A hole is bored upwards through the centre of the spindle, passing up from the lower end, nearly to the upper end thereof, and at the upper end of the hole is fixed a brass cup, which is to rest on the top of the fixed brass spindle. The wooden spindle is of such a length that the disc carried at its lower end shall be at a distance above the table or bench. The lower end of the hollow spindle is made to fit closely to the bottom of the fixed metal spindle, so that the frame may turn truly in a horizontal plane around the spindle, without swaying or oscillating. By this arrangement for supporting the revolving frame, all risk of explosion is avoided, as the metal bearing which supports the frame, and upon which it turns, is surrounded and enclosed by the hollow wooden spindle. The upper and lower discs of the frame are at a distance apart from one another, somewhat less than the height of the flasks, canisters, or receptacles to be filled. Through the upper disc holes are bored, at equal distances apart from one another, around its outer circumference. As many holes are bored through the disc as the number of flasks, canisters, or receptacles the frame is intended to hold. Above each of these holes is a funnel, with a descending tube, which passes down through the hole in the disc. On the upper surface of the lower disc are placed radial divisions, between which the lower ends of the flasks, canisters, or receptacles to be filled with powder are held. To place the flasks into the frame, the mouth of the flask is first placed over the lower end of the tube, descending from one or other of the funnels carried by the upper disc the lower end of the flask is then moved inwards towards the central pivot, to bring the flask into a vertical position; the bottom of the flask will then rest on the upper surface of the lower disc. The upper outer edge of the lower disc is bevelled off; a guard, ring, or hoop, is fixed around the hollow spindle to act as a stop to prevent any of the flasks being pushed in too far. When using this apparatus for filling flasks, the revolving stand is first filled with as many empty flasks as it is constructep

to hold, measured quantities of powder are then poured in succession into each of the funnels carried by the revolving stand, and this is readily done, as the person filling the flasks can bring them round in succession to receive their charge of powder.—Patent abandoned.

3079 J. GILMOUR. *Improvements in the construction of pianofortes.* Dated November 1, 1867.

This invention relates to improvements in the construction of pianofortes, and consists, in the first place, of a means for resisting or counterbalancing the great strain of the strings or wires upon the framing to which these are attached. The counterbalancing arrangement consists either of a plate, the full length of the frame, or the beam known as the "pinblock," or "rest block," into which the tuning pins or screws for tightening the wires are placed. In place of a continuous plate, several strips, bars, or small plates may be fixed on the upper and lower "pinblocks," and at the outer or back end of these plates, strips, or bars, eyes, or hooks are placed, to which are again attached metallic rods, with screw couplings. These arrangements are situated on that side of the framing opposite that to which the strings are applied, so that by tightening or loosening the screw couplings, the whole frame may be very effectually balanced, so as to resist the tension of the strings. In place of having the strain all on one side, as at present, the double strain produced by this arrangement is maintained constantly in a perpendicular direction on the upright posts, technically termed the "bracings," to which the "pinblocks" are attached. Thus, by providing resistance to the tension of the strings, by means of an opposing strain, the perpendicular "bracings" and supporting posts can be made of much less "scantling" than at present. In connection with this invention a hollow or belly-shaped soundboard may be used, resting against a wooden partition fixed in front of the bracings or upright posts; the soundboard is supported by a rim and sound pins, or posts, similar to those used in violins, and having openings of suitable shape cut in it to facilitate the reverberation of the sounds of the strings. The soundboard may be fixed by means of ligatures, or by the pressure produced through the tension of the strings, or by other convenient means, thus imparting great freedom of vibration, which, combined with the hollow formed by the back partition, affords additional power to the tone, at the same time adding to its quality. The mode of counterbalancing the strain described, has the advantage of enabling the uprights and rest plates or the pinblocks to be made wholly of iron, or the former of iron tubes of a light and, if desired, ornamental character; such construction is suitable for hot climates, where the temperature greatly affects timber. The second part of the invention relates to the tuning of pianofortes, and, in order to gain complete accuracy in this respect, and, at the same time, rigidity of tension, there are applied on the top of the pinblock bars, or strips (which may be made either of wood or iron), having a hook or hole at the front end, to which the strings are attached. At a short distance from the front end, a screw passes through each strip, the point of which pressing on an iron plate placed on the pinblock, so that when the screw is turned, the strip is raised or depressed, and the pitch of the string it at once regulated to the utmost nicety, and with the greatest ease. At the back these strips of metal may either be hinged or simply held down by a bent piece of metal.—Patent completed.

3080 S. PARR and A. STRONG. *Improvements in the construction of buildings, arches, bridges, coffer-dams, wharf walls, and such like structures, and in the floors and roofs of buildings, and floors in other situations.* Dated November 2, 1867.

The object and intention of these improvements is to cover, enclose, or divide floor buildings and open spaces with materials of different kinds, combined together in a novel manner, for insuring strength and economy in the construction, and for rendering them fireproof, and, further, to construct arches and bridges, and suchlike structures, of greater strength, with less materials than at present used.—Patent abandoned,

3081 J. WRIGHT and M. B. NAIRN. *Improvements in power looms.* Dated November 2, 1867.

This invention has principally for its object, by an improved construction, to render power looms suitable for weaving very wide and heavy fabrics, such as floorcloth, canvas, of, for example, eight yards in width, and the patentee's said invention comprises the following principal features of novelty, namely,—first, the actuating of the lathe by cams, which keep it back for a length of time sufficient for the passage of the shuttle, and allow it to beat up by the action of gravitation, alone or combined with springs. Second, the actuating of the picking levers by gravitation, or by means of weighted levers, which are raised and let fall by cams. Third, the arranging of the driving gearing in duplicate at the two sides of the loom. Fourth, the actuating of the lathe or shuttle, or both, by means of cylinders and pistons. Fifth, the actuating of picking shafts by cams or wipers, on shafts revolving more quickly than the latter cam shaft. The invention cannot be fully described without reference to the drawings.—Patent completed.

3082 M. A. SOUL. *Improvements in the mode and means of securing the metal bolts employed in the construction of timber ships and other structures.* (A communication.) Dated November 2, 1867.

This invention consists, first, in an improved mode of fastening the bolts. The bolt having been driven in the ordinary manner is, at its end, screwed or provided with a thread, by means of a suitable tool or instrument, and the wood surrounding the end of the bolt having been cut out by another tool suitable for the purpose, a metal nut is screwed on the bolt end, so as to fit the countersunk recess thus formed. Where the invention is to be applied to ships already built upon the system of clenching, the clencher and the washer ring are first removed. The invention consists, second, in the instrument or tool for cutting the thread on the bolts, which is a die stock of novel and peculiar construction, composed of two semicircular dies, held together and adjusted by suitable screws, springs, and collars. This instrument is used for the purpose of cutting the thread on the bolts, when in their proper position. The invention consists, third, in the instrument or tool for cutting or forming the countersunk holes in the wood, for the reception or admission of the metal nuts.—Patent abandoned.

3083 W. DARCEY. *Improvements in fastening and strengthening gates, and in the means employed therefor.* Dated November 2, 1867.

This invention relates, in the first place, to an improved latch and catch for securely retaining gates when shut, at the same time so arranged that the gate may be easily opened. The latch consists of an iron bar, movable, on a central pin, fixed into a socket in the end upright of the gate. The outer part of it passes into the catch and is firmly supported by a staple, and the inner end of the latch may be provided with a weight, so as always to maintain the latch in such position that it must fall into the catch as the gate is shut. The catch consists of an iron frame or staple, driven or otherwise fastened into the gate post. The under side of the catch is formed inclined, until the catch itself is met by the inclined portion, so that as the gate is being shut, the latch is depressed by the inclined part of the catch until the notch is met, into which the weight of the opposite end raises it, and by which the gate is then firmly secured. The staple in the gate that acts as a support to obviate the lateral strain on the latch also passes over the catch staple in the gate post, and thus adds to the security of the fastening. The second part of the invention relates to an application for strengthening gates. It consists of an iron strap fixed to the upper bar of the gate, and in the back end of this strap a bar is fixed by nuts. The bar is secured to the upper part of the heel of the gate, thus forming an efficient stay or support to the body of the gate, whilst, at the same time, if it is ever required to tighten the joint of the gate, this is effected by tightening the nuts on the screwed part of the bar.—Patent completed.

3084 J. SCOTT. *Improvements in shades for gas and other lamps, and in the mode of fitting or applying the same.* Dated November 2, 1867.

This invention relates to a peculiar construction of shades for gas and other lamps, and to the mode of fitting and applying the same to such lamps, the object being to obtain a continuous rotatory motion of the shade, so long as the light enclosed is burning, whereby an excellent medium is obtained for the display of advertisements and business announcements of all kinds, or for showing a succession of ornamental designs, views, or other devices, which are to be printed or otherwise produced on, or attached to, the surface of such revolving shades. In carrying out this invention it is proposed to manufacture a shade of any desired shape or configuration, and of any suitable material, whether opaque, transparent, or semi-transparent, or translucent, and to fit or mount into the upper end of such shade. A ventilator or horizontal fan, composed of a number of inclined blades of metal, &c., or in lieu thereof, an Archimedean screw or spiral blade, may be used. Through the centre of the said fan or spiral there is passed a pin or vertical pivot, upon or round which the shade is caused to revolve by the action of the ascending current of hot air from the flame upon the inclined blade or spiral. This pivot or centre is carried by a tripod or other conveniently shaped metal clip, which is made to fit the upper rim of the chimney or globe of the lamp.—Patent abandoned.

3085 A. G. AVENELL. *A new or improved frame or support for packing or carrying bottles in cases, together with a new or improved hinge for boxes and cases.* Dated November 2, 1867.

The patentee claims, first, the construction of a frame or support for bottles (fitting loosely into a case), whereby the bottles are supported either with their necks down or up, substantially as described.—Patent completed.

3086 W. E. GEDGE. *An improved hat cover.* (A communication.) Dated November 2, 1867.

The improved hat cover, which is the subject of this invention, is made from sheet india-rubber and in one piece, and by adopting this material a hat cover is obtained not only waterproof but tight and portable, in a very small compass, of any desired colour, and economical in manufacture (being of one piece), but also possessing an elasticity which will permit it to adapt itself to hats varying in size and shape, thus obviating the necessity of a particular cover to each different hat.—Patent completed.

3087 H. W. GRYLLS, H. NEVILLE, and J. HOLT. *Improved apparatus for obtaining and applying motive power.* Dated November 2, 1867.

This invention consists in an improved arrangement of drum coil or other springs for obtaining and applying motive power, for the propulsion of railway and other kinds of land carriages, ships, boats, and vessels for sea or river navigation; also for driving machinery for manufacturing purposes, and for propelling balloons and other aerial machines.—Patent abandoned.

3088 R. PARRY. *Improvements in corsets.* Dated November 2, 1867.

The inventor proposes to form the body of the corset in two parts, separated at the sides, the two edges on each side to be joined or laced being furnished with eyelets, through which the laces are passed as follows:—The lace is first passed through the top eyelets of the back of the body, through the corresponding eyelet of the front, then brought back through the next lower eyelet, and through the corresponding back eyelet, and the two ends are brought round together to the front, then a new lace is similarly passed through the next four eyelets, and so on all down the sides of the corset. The ends, or pairs of ends, are then attached to a tab or strap on each side of the corset; these tabs are provided with eyelets, when, by pulling the two tabs together towards the front, the whole series of laces will be simultaneously tightened, and the tabs are then secured to a hook attached to the lower part of the front or middle busk of the corset. The invention consists, second, in a new method of securing the ends of the busks from escaping from the corsets.—Patent abandoned.

3089 J. J. HICHS. *Improvements in the manufacture of backs and handles for brushes.* Dated November 2, 1867.

For the purposes of this invention, the patentee employs earthenware of a colour closely to imitate that of ivory, the colour being applied to the entire substance of the "body," or only to the surface thereof as will be well understood. The mode in which he prefers to make and apply the backs and handles for hair, and other similar brushes, is as follows:—He moulds or shapes the back and handle to any desired pattern, and in one piece of the "clay" or "body," such back being provided with an undercut recess in the face thereof. The bristles are inserted in a suitable foundation, and such foundation is placed in the undercut recess, where it is held by cement, or by other suitable means.—Patent completed.

3090 A. M. CLARK. *Improvements in apparatus for producing motive power.* (A communication.) Dated November 2, 1867.

This invention consists in arranging a series of hydraulic bellows around the perimeter of a vertical wheel, and operating them by means of cams on the spindle upon which the wheel runs, so as to force the water from one bellows into another, at certain points of the wheel's revolution. The weight of the water thus transferred from one point of the perimeter to another rotates the wheel, and furnishes the motive power.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated March 18, 1868.

916 W. Clarke, Gateshead, Durham, and E. Walker, Poplar, Middlesex. Improvements in capstans.

922 R. Townsend, King Henry-street, Ball's Pond, Middlesex. Improvements in breech-loading firearms.

Dated March 24, 1868.

996 R. A. Hardcastle, Rye Hill, Newcastle-upon-Tyne. Improvements in the manufacture of iron and steel, and in apparatus employed therein.

1000 R. Smith, Chorlton-upon-Medlock, Manchester, machinist. Improvements in machinery for winding cotton, silk, and other yarns or threads, on to spools, cards, or balls, and in additional apparatus to be used when winding balls for ticketing the same.

Dated April 4, 1868.

1148 J. Griffiths, Chesterfield, Derby, manager, and J. Jeavons, Sheffield, manager. Improvements in the manufacture of piles of iron or steel, or of iron and steel for the manufacture of rails, angles, axles, tyres, shafts, and other articles.

Dated April 9, 1868.

1202 L. Verstraet, Boulevart St Martin, Paris, chemist. Improvements in the means of, and apparatus for, storing and burning petroleum and other inflammable oils for heating steam boilers, and for other purposes.

Dated April 11, 1868.

1210 G. Clark, Northumberland-street, Strand. Improvements in the manufacture and production of explosive compounds, and in apparatus for their manufacture and use.

Dated April 14, 1868.

1229 A. and L. Braham, Manchester. Certain improvements in the manufacture of hats or coverings for the head, called sou' westers.

Dated April 15, 1868.

1240 R. Oxland, Compton Gifford, Plymouth. Improvements in the treatment of ores and minerals containing copper to extract copper therefrom.

Dated April 17, 1867.

1257 D. Smith, Southampton-buildings, Chancery-lane. An improved mode of securing tubes in steam boilers and other vessels. (A communication.)

1263 A. P. Price, Lincoln's Inn-fields, consulting chemist, and J. A. Wanklyn, Professor of Chemistry at the London Institution, Finsbury Circus. Improvements in the preparation and use of anæsthetics.

Dated April 18, 1868.

1264 T. Bradford, Argyll-square, London, washing machine manufacturer. Certain improvements in machinery or apparatus to be employed for churning, which is also applicable for washing textile fabrics and mixing liquids.

1265 G. Lister, Rivers, Dursley, Gloucestershire, manufacturer. Improvements in machinery or apparatus for feeding slivers of wool or other filamentous materials to carding and condensing engines or machines.

1266 E. T. Hughes, Chancery-lane. Improvements in the manufacture of hats and bonnets, and in the apparatus employed therein. (A communication.)

1267 J. Hargreaves, Darlington, Durham, analytical chemist. Improvements in obtaining phosphates and phosphatic manures.

1268 R. Scholefield, Leeds, mechanic. Improvements in brick-making machinery.

1269 A. Ashley, worsted spinner, E. Rawnsley and W. P. Waite, overlookers, Horton, Bradford, Yorkshire. An improved means or apparatus for lubricating the spindles and other parts of machinery used for spinning or twisting wool, cotton, mohair, alpaca, or other fibrous substances.

1270 W. Lund, Jewry-street, City. Improvements in machines for turning off cross-head wrist pins, crank pins, and similar work. (A communication.)

1271 N. Ager, Grosvenor-road, Pimlico. Improvements in fastenings suitable for window sashes and for other uses.

1272 H. W. Widmark, Tamworth-place, Bristol, engineer. Improvements in governors applicable to steam and other engines.

1274 R. Hill, Castle-street, Bristol, auctioneer, and J. F. D'Oyly, Oak Villa, Walthamstow, Essex, master mariner. Improvements in paddle and other wheels used in air or water for propelling or driving ships, vessels, and machinery.

1275 A. B. Childs, Mark-lane, City, engineer. Improvements in the grinding surfaces of millstones, and in apparatus or machinery for forming the same.

Dated April 20, 1868.

1277 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in the means and appliances for press copying letters and other written documents. (A communication.)

1278 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in the treatment of textile fabrics for consolidating them and rendering them impermeable. (A communication.)

1279 J. Cooke, Darlington, Durham, mining engineer. Improvements in the construction of rotary engines and pumps.

1281 J. and J. A. Fawcett, Wakefield, Yorkshire, corn millers. Improvements in steam boilers or apparatus for generating steam.

1282 J. B. Farrar, Halifax, machine maker. Improvements in spinning and doubling machinery.

1283 W. Malam, Old Kent-road, Surrey, gas engineer. Improvements in the manufacture of gas and in apparatus employed in such manufacture, part of the invention being also applicable to the manufacture of retorts, retort casings, crucibles, and melting pots for various useful purposes.

1284 J. McGhie, Glasgow. Improvements in apparatus for spinning or twisting.

1285 S. W. Worssam, jun., King's-road, Chelsea. Improvements in machinery or apparatus for planing and cutting wood.

Digitized by Google

1286 W. W. Symington, Chard, Somersetshire, engineer. Improvements in machinery for sizing, tarring, dyeing, drying, and finishing laid and other twines, lines, yarns, threads, and fibres.

1287 J. J. R. Humes, Deptford, Kent, and J. G. Sullivan, New Cross, Kent. Improvements in machinery for making bricks.

1288 A. V. Newton, Chancery-lane. Improvements in the construction of rings for ring spinning. (A communication.)

1289 G. Coles, Gresham-street West, City, merchant, J. A. Jacques, chemist, and J. A. Fanshawe, engineer, Tottenham, Middlesex. Improvements in the manufacture of elastic bands.

Dated April 21, 1868.

1291 A. Cole, Erith, Kent, merchant's clerk, and J. Carter, Bexley Heath, Kent. Improvements in, and applicable to, lamps in use in railway carriages and in similar situations.

1293 W. Gorse, Birmingham, machinist. Improvements in the preparation of strips of iron and steel for the manufacture of flat-pointed cut nails.

1294 E. Kemp and H. Gourlay, Dundee, Forfarshire, engineers. Improvements in marine steam engines.

1295 A. Paget, Loughborough, Leicestershire, manufacturer. Improvements in apparatus for the hauling, tightening, or pulling of ropes, cords, chains, bands, and other mechanical equivalents, and for the holding or making fast such ropes or other mechanical equivalents, and loosing the same when desired.

1296 G. Coles, Gresham-street West, City, merchant, J. A. Jacques, chemist, and J. A. Fanshawe, engineer, Tottenham, Middlesex. Improved machinery or apparatus for producing thin strips or filaments from various substances.

1297 L. Bing, Bishop's Stortford, Hertfordshire. An improved mode of, and apparatus for, ascertaining the actinic power of light.

1299 A. D. Renshaw, Fetter-lane, City. Improvements in apparatus for shearing or clipping the wool or hair of animals, and in the means for operating the same.

1300 J. H. Johnson, Lincoln's Inn-fields. An improved mode or method of correcting the deviations of the mariner's compass in iron ships. (A communication.)

1301 J. and H. T. Fugl, Woodbridge-street, Clerkenwell, upholsterers. Improvements in curtain poles and laths.

Dated April 22, 1868.

1302 M. S. Maynard and R. Grime, Preston, Lancashire, cotton spinners. Improvements in machinery for governing the speed of motive power engines.

1303 J. Johnson, Levenshulme, near Manchester, millwright and engineer. Improvements in metallic packings for pistons, pump buckets, and valves.

1305 W. Clarke, Nottingham, lace manufacturer. Improvements in the manufacture of ornamental fabrics in twist lace machinery.

1307 C. B. Ingham, Manchester. Certain improvements in apparatus for stamping, dating, indicating, or otherwise impressing marks or designs. (A communication.)

1308 T. Whittaker, Manchester. Certain improvements in the manufacture of water or liquid-proof fabrics or surfaces.

1309 H. Howse, Lime-street, City, accountant. An improvement in the manufacture of safety matches.

1315 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for manufacturing small articles from sheet metal. (A communication.)

1316 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in carpet linings, and in machinery for manufacturing the same. (A communication.)

1317 H. Hill, Nottingham, brass founder. Improvements in water-closets, and in ball and other cocks, taps, and valves.

1318 W. E. Newton, Chancery-lane. Improvements in paddle-wheels for vessels. (A communication.)

1320 H. H. Murdoch, Staple Inn, Middlesex. Improvements in the construction of concaves or breasting for the beating drums of thrashing machines. (A communication.)

1321 R. F. Fairlie, Gracechurch-street, City. Improvements in railway carriages and waggons, and in the means of coupling them together to form trains.

1323 E. Samson, Little Anchor-street, Bethnal Green, Middlesex. Utilizing the hoop, rim, or frame, under the top of an ordinary loo, centre, or other table, whether circular, oval, or any other shape.

Dated April 23, 1868.

1324 W. Hamilton, Glasgow, engineer. Improvements in the generating of steam, and in the means or apparatus employed therefor.

1325 T. Hardcastle, Lancashire, bleacher, dyer, and calico printer. Improvements in the manufacture of bowls for mangles, washing machines, and other purposes.

1326 E. Rostron, felt manufacturer and printer, and W. W. Whittaker, mechanic, Waterfoot, near Manchester. Improvements in machinery employed in the manufacture of felt.

1327 J. Whitehouse, Tipton, Staffordshire, ironfounder. Improvements in the manufacture of tailors' or goose irons.

1328 J. Bush and H. Welchman, Aston-juxta-Birmingham. An improved spring fastening for brooches and other similar dress fastenings.

1330 G. F. and J. Stidolph and T. Simpson, Woodbridge, Suffolk. Improvements in brushing and sweeping machines.

1331 A. M. Clark, Chancery-lane. Improvements in apparatus for transmitting and multiplying motive power. (A communication.)

1335 J. Reid, Glasgow. Improvements in the manufacture of casks and other similar articles, and in the machinery or apparatus connected therewith.

1337 J. Casson, St. James's-street, Sheffield. Improvements in machinery for sawing wood.

1338 A. Carter, Birmingham, accountant clerk. Improvements in machinery for the manufacture of nails, spikes, and bolts.

1339 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in cartridge boxes or holders. (A communication.)

Dated April 24, 1868.

1343 C. Brown, Dublin. Improvements in apparatus for baking, also applicable to hot pressing, and to other heating and to cooling purposes.

1345 R. and T. Nuttall, Walmsley, Lancashire, and B. Barber, Manchester. Certain improvements in the manufacture of woven fabrics termed quiltings and toiletings, and for similar descriptions of fabrics.

1347 C. W. Harrison, Oberstein-road, Clapham Junction, Surrey. Improved means of preventing incrustation in boilers and other vessels in which water is heated.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated April 29, 1868.

1400 J. Booth, Gamble-street, Nottingham, draughtsman. Improvements in the manufacture of fabrics in twist lace machines.

Dated May 2, 1868.

1434 H. A. Bonneville, Sackville-street, Piccadilly. Apparatus for measuring and registering the flow of liquids. (A communication.)

1446 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in buckets and other vessels of wood of analogous form, and in means for producing the same. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," May 12, 1868.

3699 T. and J. Robertshaw and J. Greenwood. Looms for weaving.

3713 V. L. Daguzan. Construction of paving.

4 G. A. D. Goodyar. Machinery for propelling boats.

5 W. Stroudley. Re-railing waggons.

9 R. W. Morrell and P. Craven. Spinning fibrous substances.

11 J. Imray. Locomotion.

12 C. W. May. Metallic cartridges.

20 E. Izod. Stays.

23 T. P. A. Key. Scaffolding.

25 J. and B. Dellagana. Printing machines.

26 M. E. Roy and L. Prevett. Receptacle for containing needles.

29 W. W. Morley. Bag machines.

30 W. J. Blinkhorn. Manufacture of dip candles.

34 A. Albini. Cartridge belts.

37 J. Nixon. Apparatus for transferring coal from railway waggons into barges.

39 E. R. Southby. Separating paraffin from its solutions.

41 T. Stokes. Manufacture of piled fabrics.

47 E. Myers and G. A. Cannot. Permanent way of railways.

63 G. E. Donisthorpe. Construction of catches for brooches.

67 J. Tomlinson. Machinery for twisting flax.

68 L. Simon. Laying metal leaves on printed surfaces. (A communication.)

72 C. Pontifex. Presses for expressing wort from spent hops.

102 A. Budenberg. Steam hammers. (A communication.)

113 G. Ireland. Cruet frames.

118 W. Firth. Valves made from india-rubber.

126 T. Sagar and T. Richmond. Looms for weaving.

136 J. Williamson. Bolting one part of a ship to another.

146 C. E. Brooman. Cooking apparatus. (A communication.)

166 J. M. Napier. Apparatus for cutting metals.

183 B. J. Heywood. Manufacture of pencil-cases.

271 J. H. Johnson. Apparatus for melting metals. (A communication.)

329 W. E. Newton. Window sun blinds. (A communication.)

515 L. Mummenhoff. Compositions for the manufacture of building blocks. (A communication.)

885 W. and W. Arthur. Truss.

975 H. Paulus. Pile driving engine.

1270 W. Lund. Machines for turning off cross-head wrist pins. (A communication.)

1295 A. Paget. Apparatus for hauling ropes.

1308 T. Whittaker. Manufacture of waterproof fabrics.

1320 H. H. Murdoch. Construction of concaves for the beating drums of thrashing machines. (A communication.)

1345 R. and T. Nuttall and B. Barber. Manufacture of woven fabrics.

1400 J. Booth. Manufacture of fabrics in twist lace machines.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the lis of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 8, 1868.

3170	S. Simon	3264	C. E. Brooman
3173	C. Bedells	3273	R. Ward and T. Travis
3177	J. H. W. and A. W. Biggs	3292	J. Owens
3179	W. Payne	3321	C. E. Brooman

WOOD BROTHERS'
PATENT OBLIQUE TRANSVERSE TUBES
For the Flues of Cornish Steam Boilers.

THESE Tubes are exceedingly simple in construction and application, and very durable. They give a greater amount of heating surface than any other transverse tube that can be put in a flue of the same diameter, consequently will generate more steam with greater economy of fuel, and they can be repaired or replaced much more readily than any others.

As these Tubes are put in obliquely, and at a proper inclination, having the flanches at both ends inside the flue, they may be put in or taken out of their places through the flue without passing inside the boiler at all, thus giving the opportunity of applying them to boilers already in use without disturbing them or taking out the flues, whatever be the relative dimensions of the shell and flue.

FOR PRICES, AND A LITHOGRAPH OF THE BOILERS, APPLY TO
WOOD BROTHERS, DON BOILER WORKS, SHEFFIELD. B 1

LONDON: FRIDAY, MAY 22, 1868.

PROPOSED SYSTEM FOR GIVING INFORMATION OF STORMS.

WE have before us an explanation issued by the Meteorological Committee of their proposed system for giving information of storms. Whenever any of the daily telegrams of the weather, received at the Meteorological Office from the reporting stations, give information of an actual storm, that information it is proposed to transmit to the seaports by electric telegraph, and to announce it locally by a semaphore erected for the purpose. The objects of the system are to make known the direction from which a gale was blowing at 8 a.m. of the day in which the semaphore is in use; to indicate the district in which the gale is blowing, and whether within or without a certain defining circle; and to show the force of the wind. It seems intended more especially for the coasts of England and the adjacent seas, as Scotland and Ireland are beyond the centrical area. At all events, it does not appear to us that either Scotland or Ireland will derive much, if any, advantage from the proposed system, although the Scotch in particular were very clamorous for the renewal of Admiral Fitzroy's storm warnings, which they very highly appreciated.

To understand how these objects are to be carried out, the semaphore must be described. A circular frame, about 6ft. in diameter, is mounted vertically upon a stout pole 24ft. high. From its centre radiate two arms of unequal length, which can be revolved about its centre independently of each other by means of appropriate gearing, and can be fixed in any required position with respect to the circle, which carries upon its circumference letters corresponding to the eight principal points of the compass, N. being uppermost. Thus it resembles a clock face, N. standing in the place of XII., E. in place of III., S. in place of VI., and W. in place of IX., the long arm corresponding to the minute hand, and the short arm to the hour hand. The long arm is red, has the word "Wind" upon it, and shows the direction from which a gale is blowing. The short arm is green, has the word "District" upon it, and indicates the district in which the gale was blowing at 8 a.m. In connection with the fixed apparatus a movable black ball and a set of numerals (7 to 12 we presume) are employed. A numeral is to be exhibited on the post, just below the circle, to express the force of the gale, as—7, moderate gale; 8, fresh gale; 9, strong gale; 10, whole gale; 11, storm; 12, hurricane; being part of the well-known Beaufort notation for the wind's force. A ball, about 18in. in diameter, is to be hoisted immediately under the figure, showing the force of wind, whenever the gale is reported as blowing in a district within the defining circle. When the gale is outside that circle no distinguishing mark will be fixed on the post, under the force of wind.

The apparatus and mode of work require no further explanation. It is only necessary to bear in mind that the arms are to be viewed in front, when they show red and green, their backs being white; and that the mounted circle, or dial, has no reference to the points of the horizon or to compass bearings. Any seaman might readily sketch out the semaphore and understand its purpose—it is sufficiently simple. But the indispensable key to the whole thing is the map showing the districts. Such a map accompanies the official explanation; and, unless a copy can be supplied to the seaman, or he makes out one for himself, he cannot hope to understand the precise meaning of the signals. The seamen will find little difficulty in defining the districts upon a Mercator's chart, by following the subjoined directions. From Birmingham, as a centre, draw across the British Isles and adjacent seas the rhumbs NNW. and NNE., and name this the north district; NNE. and ENE. define the north-east district; ENE. and ESE. the east district; and so on similarly until the eight districts are defined. Then from Birmingham, as a centre, describe a circle to pass through Penzance. This circle will include England and Wales, the Irish Sea, the Channel, and part of the North Sea. Scotland, Ireland, France, &c., will be outside the circle. It will be well also to know the names and positions in the districts of the reporting stations, some thirty odd, which can be seen in the "Times" or "Shipping Gazette" any day.

We will now make a few remarks upon this proposed plan of signalling storms, which, while it looks imposing and comprehensive, and avoids apparently all chance of failure on the part of those charged with its manipulation, because it simply announces facts, and any approach to forecasts is carefully avoided, yet is far from perfection. Time being limited to 8 a.m., should a gale come on at any other hour, the interval till the next 8 a.m. may be sufficient time for it to extend itself all over the British Isles, and thus it will announce itself everywhere and no warning of it can be given. This we imagine will happen frequently. Even during the lapse of the two or three hours occupied in telegraphing, a gale may extend considerably from its position at 8 a.m. Thus a S.W. gale at Penzance in the early morning may be on the east coast before noon, and, indeed, may be felt in all the central districts by that time. Should a gale be telegraphed from two or more districts on the same morning two or more semaphores will be required to signal such information to any place. The expense of each semaphore will probably be twenty times as great as that of a set of Admiral Fitzroy's signal shapes. He availed himself of existing signal masts. The semaphores must have specially constructed posts; hence the expense of these semaphores will be a serious consideration, as a first outlay, and eventually for repairs. It does not appear that the arms are to be removed when not required; at least, it is not stated how they are to be disposed when not signalling. However, we must suppose there is an oversight here in the explanation. The apparatus must be viewed from the front or it is not intelligible, whereas such signals should be discernible from all possible positions within sight of it.

To announce to our principal ports the fact of a gale just commencing at Skudesnas, Cuxhaven, Helder, Brest, Corunna, Valentia, Greencastle, or Nairn, will, without doubt, be doing highly important service to shipowners, underwriters, and seamen. Coasters will be able to estimate the chance of making short voyages and getting near a safe port before bad weather overtakes them. Foreign-going ships from Liverpool or Bristol may be saved the risk of encountering a gale soon after leaving port. Ships would probably not be sent out from those ports, in the teeth of a south-wester, off the south of Ireland, and, on the other hand, ships would not be sent from our eastern ports to encounter a north-easter reported to the east of the North Sea. This system may gain favour among the seafaring community, especially in our large ports, and, if so, it appears to us it will be found to work better with less centralization. The arrangement of working from a central office can only result in delay, and that is of all things the most adverse to the utility of this system. In this matter the large ports can get the information direct for themselves, and so avoid delay. Thus Liverpool could receive by telegraph information of storms from the east, west, north, or south of the British Isles, just as easily as London, and effect a saving in time of two or three hours, which may sometimes prove of much consequence.

The semaphore supplies the defect of the drum which the Meteorological Office has been using since the commencement of the year, for the former indicates locality and direction of wind, whereas the latter does neither. The office steadfastly refuses to predict gales: it only undertakes to signal them from afar off. We cannot bring ourselves to deem their plan of operation better or equal to that of Admiral Fitzroy His system gave two or three days' notice, and warned all coasts likely to feel the coming gale. It was extremely simple and almost inexpensive. It is obvious that the semaphore can only be adopted at large seaports or in immediate connection with a telegraph station. Small ports and fishing villages will still have to make the most of the drum. On the whole, while we regard the semaphore as a costly improvement on the drum, we still think the latter might be replaced, where the former is not adopted, by cone "point down" for equatorial gales, and cone "point up" for polar gales.

THE SILVER COINAGE OF GREAT BRITAIN.

IN a previous paper on this subject* it has been shown that, even supposing the present inconvenient duodecimal system of coinage to be maintained in this country, it is highly desirable to cancel altogether three denominations of coin now in circulation, namely, crowns, half-crowns, and fourpences, There would then remain to us florins, shillings, sixpences, and threepences, and these, it must be admitted, would, if arranged correctly, and preserved in proper condition, answer all the purposes for which a silver currency is required. In order, however, to make these coins more useful, more creditable to the great community among whom they circulate, and more worthy of the mint whence they emanate, they should be made to harmonize with each other. At present there is apparent an absurd incongruity in the designs ornamenting the various denominations in question. The florin has no sort of family resemblance to the shilling either of George III., George IV., William IV., or Victoria, numerous specimens of which are in existence at this hour. The sixpence of the current reign certainly does present *fac similes* of the devices ornamenting the shilling of the same period, but its reverse is totally dissimilar to that of the threepence! We do not know who is responsible for these infelicitous arrangements, which are attended with great annoyance to the public, and reflect no credit upon British art, but somebody is to blame for them. Whilst, then, we suggest, and, indeed, strongly urge, the withdrawal altogether of the three effete coins previously referred to, we no less earnestly advocate the relegation to the Mint melting pots of all shillings and sixpences of a date anterior to that of the accession of Queen Victoria. Their places, of course, should be supplied by further and extensive issues of new coin with as much speed as possible. It is very unfortunate that the designs of the obverse and reverse of the florin are so totally different in character to those of all other English coins, and that so many millions of them are in circulation. The coin is, as it were, an exotic. Its origin may be traced clearly to German sources, and it will never be thoroughly naturalized. Had it borne a head of her Majesty, unadorned, like that which distinguishes the three lesser coins of silver, and a reverse presenting a wreath of oak and laurel enclosing its value expressed in plain Roman letters, it would have been far more appropriate and acceptable. The florin

* *Vide* MECHANICS' MAGAZINE, April 3, page 250.

Digitized by Google

is, nevertheless, engrafted on the English stock of coins, and cannot now be separated from it. The evil is to be regretted, but it cannot be remedied—at present. It is too late or too early to recommend the withdrawal of the florin, but it never has been, and never will become, a popular coin in this country.

To return to those denominations of silver coin which are susceptible of improvement, we say that they should be forthwith remodelled. In removing from circulation all shillings and sixpences of past reigns, and replacing them with those of the present, two excellent points would be effected. Shabby and worn coins would disappear almost entirely, and uniformity of design would characterize those which remained to do duty. It must be allowed that there might be some difficulty in recognizing the "image and superscription" which originally figured upon many of the shillings and sixpences now in circulation, for attrition has nearly obliterated them. That difficulty could be overcome by including in the sentence of extermination such pieces as could neither be made "head nor tail of," or were denuded of all Mint marks. There are thousands of these ghosts of coins still haunting the busy highways and byways of public traffic, and creating no small amount of trouble to her Majesty's lieges. They "lag superfluous on the stage," and should be driven off, and consigned to the fiery furnace without hesitation or remorse.

By the introduction of sweeping measures of the practical kind now advanced, it is our belief that the silver coinage of Great Britain may at once be beautified, utilized, and simplified. It is not enough that the circulation of obsolete and worn coins should be gradually stopped as they now are. The operation should be effected sharply and suddenly under warrant of Royal proclamation. In plain terms, the silver coinage of these realms deteriorates at a more rapid rate than its reproduction at the Mint makes compensation for, and hence its disgraceful condition. This is not a discovery, however, for which exclusive credit is claimed by ourselves. The fact is, unfortunately, too well known—outside the walls of the Mint, if not within them.

The longevity of coins generally has been much reduced since railways came into being. They are in continual motion from the time of their birth, and the poor sixpence especially is shortlived, in consequence of being overworked. If "one man in his time plays many parts," assuredly one coin in its course buys many times its own value. A certain charge is made annually in the Mint estimates for covering the loss accruing from the purchase of worn shillings and sixpences. These are bought of the Bank of England at their nominal value, and, of course, are bad bargains for the coining establishment which recasts, and then recoins them into money of full legal weight. The last amount granted for the purchase of worn silver coin amounted to £15,000, or 300,000 shillings, and this was supposed to represent the extent of one year's (1867) abrasion and deterioration of the silver coinage of the United Kingdom. Experience demonstrates that the annual loss of silver by the attrition of coins is in these days of trading activity much greater in value than this, although the weight of the silver thus spirited away in one year by friction is set down at 56,362 ounces!

This heavy loss, the expense of which falls upon the public, suggests other questions in reference to the silver coinage. One of these has reference to the mechanical formation of the pieces of money. Is it not possible so to manufacture shillings, for example, as that they shall not suffer so greatly as they now do from the wasting effects of attrition? Cannot their engraved surfaces be better protected? Is it not within the compass of scientific skill to harden the metal of which silver coins are composed, without reducing its standard of fineness? These and other problems remain to be solved on a future occasion. They are of importance at present, and they will become infinitely more so should the decimalization of the coinage of Great Britain be one day agreed to.

SAFETY GUN COTTON.

NOTWITHSTANDING the vast superiority of gun cotton over gunpowder as an explosive agent, its general adoption for blasting purposes has been greatly retarded by the presence of one fatal drawback which it has hitherto possessed. This drawback has been the resistless energy developed in its combustion under all circumstances, and which has led to a well-grounded fear of its power in case of accidental explosion. The practical result of this defect has been a want of confidence in gun cotton by users of blasting materials, and the raising of difficulties in the way of its transit by railway companies and other carriers, for its excessive violence rendered it more dangerous even than gunpowder. The great difficulty, therefore, has been so to modify the manufacture as to produce a material which would be perfectly under control, that is, which would only burn if accidentally ignited in transit or in store, but which would give out all its energy when properly confined for work. This question has for long past been the subject of careful investigation by the Gun Cotton Company, whose works are at Stowmarket, and we are glad to find that they have satisfactorily solved it. They are now manufacturing an article which will not explode under any other conditions than those of actual use. The way in which this is effected consists in pulping the cotton upon Professor Abel's principle, and then compressing it under a pressure of 18 tons to the square inch. To the pulping mainly is due the safety attained, as it ensures uniformity in washing, whereby the cotton is thoroughly freed from all acid, and thus every chance of spontaneous combustion is removed. The compression causes combustion to proceed slowly in the open air, owing to the condensed condition of the fibres, which, in the loose state of cotton or rope, burn very rapidly. The gun cotton is made into small cylindrical charges, which are both portable and convenient for use. The principle of thus combining safety with force in a highly condensed form has produced invaluable results; a series of severe trials, extending over a considerable period, have proved gun cotton in its present improved form to be the safest and strongest, and, therefore, the most economical explosive agent.

The great point is, of course, to win public confidence, which has been greatly shaken by occasional explosions of nitro-glycerine. To do this it was necessary to demonstrate the existence of safety, and to prove the absence of all ground of alarm. To this end the North-Eastern Railway Company directed a series of experiments to be made, which were lately carried out by Mr. Prentice, the managing director of the Gun Cotton Company. Mr. J. Wilson, the goods manager of the Railway Company, directed these experiments, and we have his report upon them before us. First, a small box containing 125 charges of the gun cotton, and said to be equal in effect as a blasting agent to a quarter cask of gunpowder, was ignited by a fuse. When the flame reached the gun cotton, there was a great blaze like the burning of a heap of loose straw, but no explosion. In less than half a minute there was no flame, except from the burning of the brown paper in which the gun cotton had been packed inside the box. The box was of wood about ¼in. thick, and was nailed, but not bound with iron at the corners; it was one of the ordinary packages used for sending the cotton out.

After this a number of charges were laid on the rails near the coal depôts, and coal waggons were run over them, when some of them were ignited, others were not. Some charges were then placed so that an engine should pass over them, and they were all ignited. Mr. Prentice took an axe and chopped one charge into several pieces; there was no explosion or ignition. Small pieces of gun cotton placed on the iron rim of a wheel and sharply struck with a hammer, exploded, or rather, detonated. In all the cases where ignition was produced by concussion, whether of a hammer on iron, or of the wheels of an engine or waggon on the rails, it was very evident that only so much as was actually struck exploded or detonated, the part not struck firing from the explosion, and burning like straw or flax. In order to make sure that he was really dealing with the article which produces such an effect when exploded in close confinement, Mr. Wilson had a hole bored in a large block of hard tough wood, in which Mr. Prentice placed a charge of gun cotton with a fuse attached to it. He then filled up the hole with broken slate tightly rammed, and fired the fuse. When the gun cotton exploded the block of wood was shivered to pieces, and the fragments were blown several yards away. The result of these experiments have convinced Mr. Wilson that the company may safely carry gun cotton along with other goods in ordinary waggons, adopting the same rules as now apply to the conveyance of cartridges. It is, therefore, satisfactory to know that the North-Eastern Company, acting on Mr. Wilson's recommendation, now carry the gun cotton as ordinary goods in covered waggons. We have ourselves fired the compressed gun cotton, and find it perfectly inexplosive so long as the atmosphere has access to it, but in which all the active energy of gunpowder—but in a greater degree—is fully developed when fired in a confined space. The public have reason to thank Mr. Prentice for this excellent result, and we hope railway and other carrying companies will have the good sense to follow the example set by the North-Eastern Company. Unquestionably, we have in the compressed gun cotton a safer explosive than gunpowder.

The application of gun cotton to gunnery purposes is a question which has not yet been satisfactorily solved, but it is now being worked out by Mr. Prentice. As a charge for ordnance and small arms gun cotton is far too violent; its rapidly developed and resistless energy bursts the piece before the inertia of the projectile is overcome. To remedy this, the action of explosion must be retarded so that the ignition of the atoms shall be comparatively slow and progressive. This has been attempted in various ways, but not with any degree of practical success. We have reason to hope, however, that the time is not far distant when gun cotton will be fully utilized in this very desirable direction. In conclusion—reverting to the immediate subject of gun cotton transport—we will give the substance of a report as to the comparative risks of gun cotton and gunpowder in conveyance, which was made by Colonel Boxer. That officer is of opinion that no greater risk of an explosion attends the transport of the compressed gun cotton charges by railway or other modes of conveyance than is incurred by the transport of ordinary gunpowder. He further states that in the event of an accidental explosion of these charges the amount of damage to life and property would not be greater than that which would result from the explosion of the same bulk of ordinary gunpowder. Finally, he thinks that the mode of packing the charges in deal boxes is preferable to that of packing in strong iron cylinders. The expression with reference to the comparative safety in accidental explosion are, of course, guarded; but we have shown that the damage would be much less with cotton

Digitized by Google

than with powder. This has in effect been certified by the North-Eastern Company in the course they have adopted with regard to its transport.

THE SMOKE INSPECTION NUISANCE.

THE Government inspector of smoke nuisances appears occasionally to be as great a nuisance as the one he is endeavouring to suppress, and to require suppressing in his turn. Not long since one of his feats was to compel a steam user to keep his furnace door shut and so cause smoke—for which he summoned the offender—although with the furnace door a little way open, as usually kept by the stoker, there was no smoke. Lately, Mr. Sandison has been pouncing upon fresh victims, some of whom have complained in the public press. Amongst others, we notice Messrs. Bayley and Rawsthorne, of the Patent Wheel Works, Newington-causeway, who have sent to the "Times" a letter of very justifiable complaint. Just a week, ago Messrs. Bayley and Co. were fined at the Southwark police-court for "unlawfully using a furnace not constructed so as to consume its own smoke." Now, these gentlemen express a "burning" anxiety to consume their own smoke. They have, at considerable expense, fitted up the best contrivance they know of to all their furnaces, and with careful stoking and with the good coals they use there need be no smoke. They have pressed Mr. Sandison to inform them what they can do more, or to state if he knows of any contrivance or patent invention that will be more effectual than their present means. He is unable to do so; the oracle is majestically silent. The injustice with which these smoke summonses are conducted is becoming notorious, and we trust will be represented in the proper quarter. Take the case under consideration as one in point. Messrs. Bayley and Rawsthorne were fined on the 15th of May because a policeman deposed that their chimney smoked for four whole minutes on the 11th of March—only two months previously! Now, how is it possible for defendants in such cases either to deny or to plead guilty after a lapse of time like this? Messrs. Bayley very properly submit that if the Government insist on all manufacturers using a smoke-consuming apparatus to their satisfaction, they should be prepared to adopt what they consider the best invention, and fine all manufacturers who do not use it. If, as the authorities state, one system will answer at one place and another at another, then the Government inspector should be a competent man authorized to bring his vast experience to bear in advising manufacturers on the best system each can adopt in abating the common nuisance. But we don't believe the smoke inspector to be a competent man, and the present procedure is nothing better than a farce. The sooner this anomalous condition of things is amended the better for all parties concerned. It is a crying shame that the innocent are made to suffer equally with the guilty, and that those who are doing their best to remedy the evil complained of are fined because they cannot compass an unattainable object. Let competent men be set to deal with the question, and to find out a remedy, the non-adoption of which should then be visited with pains and penalties.

MANUFACTURING AND MINING INDUSTRIES OF BELGIUM AND FRANCE.

THAT the technical education of workmen is more sedulously promoted in some European states than in the United Kingdom is not to be disputed, nor may it be denied that such culture gives a decided advantage to the continental manufacturer. The shipbuilding interests on the Thames, and the concerns of machine makers and other metal workers in the metropolitan counties, are, and have been for a considerable time, in a languishing condition, whereas shipbuilders and mechanical engineers on the Clyde are comparatively prosperous. The contrast is not, we believe, attributable to any single influence, but to a combination of several elements. The difference in wages paid in the two localities may have something to do with the matter, the difference in the price of coal delivered at the yards and works on the Thames and the Clyde respectively has certainly much to do with it, and it would be unwise to ignore the fact that Scotland, as well as Ireland, enjoys far greater facilities than England for the sound education of the great body of the people. If it be so, that the shipbuilders and engineers of Glasgow have cheaper coal and more intelligent workers than those on the Thames, it need not be wondered at if they can take contracts at lower prices and still realize good profits. It is late in the day to say anything concerning the money—as well as the moral—value and importance of education to both master and man. Everybody admits it now-a-days. We have discovered what we need in order to hold our own against all competitors, and we have good grounds to hope that the awakening will not exhaust itself in mere talk, but in the fulness of time bring forth an abundant harvest, of which Mr. Joseph Whitworth's princely offering may be regarded as a first fruit. While ground may have been lost in this country, and gained, comparatively, in certain localities on the Continent, we have not as yet any occasion to write "Ichabod" upon the portals of our yards and factories. The fall of England and the rise of foreign competitors are not as yet so remarkable as to excite the degree of alarm that has been expressed in some quarters. It is true that in the matter of technical—and, indeed, of general elementary — instruction, France, Prussia, and Belgium are ahead of us, but a few years may, with the adoption promptly of efficient means, enable England to take the front rank which her mineral resources, the energy and perseverance of her sons, and their developed intelligence, should command.

An interesting official return has just been published by the Board of Trade, giving the trade accounts for 1865, 1866, and 1867, of Belgium, Holland, and France. The returns of exports and imports exhibit various eccentric fluctuations, but prosperity in the main, although nothing comparable to the vastness and rapidity of the development of various branches of industrial enterprise in England. The Belgian imports of coal for the three years may appear to belie these observations, inasmuch as the consumption of coal may seem to indicate the condition of manufacturing industry. But this is not the case; the coal importations of Belgium do not represent consumption in Belgium, and are only, in fact, equal to a small fraction of the exports of coal and coke from the country. The total imports of coal were—Tonn. 73,931 in 1865; in 1866, tonn. 179,427; and in 1867, tonn. 423,005. In 1867 Belgium exported, chiefly to France, tonn. 4,487,762, the increase, as compared with the exports of 1866, being tonn. 417,546, or very nearly the same as the quantity imported. The imports arose from the high prices that ruled in Belgium.

As regards machines and machinery, the Belgian imports and exports for the three years respectively were :—

	1865.	1866.	1867.
	Kilogs.	Kilogs.	Kilogs.
Imports	4,908,078	5,437,699	5,114,305
Exports	14,447,753	11,992,201	10,841,993

Of the machinery exported only 290,161 kilogs. were to the United Kingdom, the remainder being sent to France, Holland, and the Zollverein. France and Holland are the best customers to Belgium, each taking considerably less in 1867 than in each of the two preceding years, and the Zollverein considerably more. The imports and exports of iron, in various conditions, was as follows for the three years :—

IMPORTS.

	1865.	1866.	1867.
	Kilogs.	Kilogs.	Kilogs.
Iron, ore, and fillings	340,591,769	307,799,921	322,890,778
Pig and old iron	24,864,110	32,508,242	56,233,219
Rails, sheets, &c.	1,555,576	1,579,999	2,136,652
Steel, bars, sheets, and wire	...	4,320,429	2,484,240

EXPORTS.

Rails.....	...	65,549,360	80,875,014
Sheets	...	16,884,769	12,583,376
Other kinds	...	56,328,603	55,897,705

Notwithstanding the proximity of Belgium, the greater part of the machinery, and some classes of metals, imported by Holland, are from the United Kingdom; as, for instance, of machinery imported of a total value of 2,255,000 guld. in 1867, a smaller quantity than in either of the two preceding years, the proportion sent by England was of the value of 1,206,000 guld.

Turning to France, we find that the machinery of different classes and metals imported was of the values annexed :—

	1865.	1866.	1867.
	Francs.	Francs.	Francs.
Steam engines, fixed and marine	474,409	845,850	503,532
Locomotives	100,012	117,280	326,350
Other kinds for spinning, weaving, &c.	6,106,686	8,524,827	6,004,943
Agricultural machines	263,361	368,630	513,058
Of which from the U.K....	232,551	327,326	449,067
Detached pieces of all kinds	2,624,908	2,789,931	2,134,032
Machine tools	2,044,978	2,268,622	3,079,603
Iron, ore	9,543,748	9,005,465	9,831,105
„ pig	5,887,854	6,480,693	6,690,246
Steel	283,768	997,343	2,097,811

The increase in the imports of machine tools, and of steel, are amongst the most significant figures in the return, and more distinctly than any others utter the warning, "Look to your laurels." The total value of the imports for 1867, apart from bullion and specie, was 3,155,689,000f. against 2,793,484,000f. in 1866. The total exports of France, 2,972,306,000f. value, show a decrease as compared with 1866, when they amounted to 3,180,609,000f.

THE BRITISH HOROLOGICAL INSTITUTE.

IN the present day, when the arts and sciences, exact and applied, are so fostered, promoted, and cared for, it would be difficult to point out any branch or department which has not its representative body or institute. But it would not be difficult to point out some of these institutes which are neither so well known nor supported as they deserve to be. It therefore becomes our duty, as scientific journalists, to make known these facts whenever we meet them, and to draw attention to scientific bodies which are doing the public a practical service, but which, from circumstances, in some instances beyond their immediate control, are silently but yet resolutely working on in comparative obscurity. Amongst such we may certainly class the British Horological Institute, which, although known to our readers through our columns, is not so widely known as it ought to be, nor so fully appreciated as it merits. Another opportunity offers itself for bringing this Institute before the public, inasmuch as the annual dinner took place last Tuesday evening, at the Guildhall Hotel. The chair was taken on the occasion by Mr. M'C. Torrens, M.P., the member for Finsbury, in which borough the watch-making interest is essentially located. The chairman

Digitized by Google

was supported by Sir John Gray, Bart., and E. D. Johnson, Esq., F.R.A.S. The vice-chairs were occupied by J. C. Klaftenberger, Esq., John Jones, Esq., and D. Glasgow, Esq. Amongst the company present were Professor Tennant, Messrs. Jackson (treasurer to the Institute), Holdsworth, Mylne, Schoof, Strachan, and Moore (secretary to the Institute). A goodly company sat down to an excellent dinner, and the toasts, which were of the usual loyal and patriotic character, were interspersed with songs by professionals, the evening altogether being a very pleasant one.

It is not, however, so much with the proceedings of the evening that we have to deal, but with the aim and objects of the Institute, and this with the view of bringing it more prominently before the public and of assisting it into that position it ought to, and no doubt will, one day occupy. First, then, its object is to promote the cultivation of the science of horology. It aims at making a watchmaker something more than a mere mechanical worker—master of his craft though he be. It points to loftier things, and desires that its members should view their work from the highest standpoint—that of pure science. To effect this it makes known the laws which govern the present methods of manufacture, and the direction in which improvements may be made. It arranges for the delivery of lectures and the reading of papers on horology and cognate subjects, and organizes classes for the study of mechanics as connected with the art. Then, again, there is a collection of models, and specimens of horology—some of which have been presented, whilst others are on loan—and there is a library of useful works. Besides these matters, it gives prizes for essays, and issues a journal, from which we occasionally abstract valuable information. This journal is ably edited by Mr. R. Strachan, who gives his services gratuitously, and who does his work well—two conditions of things which we rarely find combined. We are happy to learn that a movement has been set on foot, and which, we trust, will be well supported, to present Mr. Strachan with a tangible recognition of his valuable services. Finally, we may mention that the Institute building, which is situate in Northampton-square, Clerkenwell, is in electric communication with Greenwich Observatory, and Greenwich mean time is taken several times daily. We should not omit to state that, connected with the interests of the Institute, is the Clock and Watchmakers' Asylum, which is supported by voluntary contributions, and to which the members subscribe. This, too, is an object which we cannot too warmly commend to the notice of all, as none can say what adversities may lie in wait for them in the future. Now, with all these, and many other, advantages which the Institute offers to horologists, and, through them, the public, we certainly must express our great surprise that it does not occupy a more prominent position than at present. As we know our pages are read by many who are directly interested in the Institute and its working, we will point out how its interests may be best promoted.

First, then, its lectures, which though few in number, are always sound and practical, should be well attended, and their number increased. The subject-matter of the papers should be freely discussed from a purely scientific point of view, all commercial considerations being left for occasions specially appointed. Members should use their best exertions to secure the regular attendance of their apprentices and others at the classes, and it would have great effect in promoting study if premiums, either of books or of money—preferably the former—were given for proficiency. The world is now alive to the great necessity of technical education, and each in his sphere can, if he will, promote this important movement. We are not all Whitworths, nor need we be to help in this direction. There are members of the Horological Institute, who, either by means or position, can lead a hand, and to them we earnestly commend the matter; let them remember that on them the world throws the onus of responsibility. What is the practical result of technical education abroad amongst watchmakers? Why, the fact that in the collection of the Horological Institute are two watch movements, perfect specimens of work, executed by two youths at Besançon, aged respectively 14 and 16 years. And this brings us to the acquisition of knowledge by specimens and models. We believe every member, if he chose, could contribute something, great or small, to the collection now forming, either on loan or as a gift. So with regard to the library, that wants extending, and many hands here would make light work. Of course, in all this, we do not forget that there is a directing body—the Council of the Institute—to whom the members depute the management of matters. To these, first, do our remarks apply. But the members are bound to aid and assist them, and to strengthen their hands to the utmost of their power. Let them show a little less apathy and indifference to matters which are occasionally placed before them through the executive. Let them infuse life and energy into their position of membership, and we will answer for their highest expectations of success being exceeded in the end.

So far, we have endeavoured to show what the Institute owes to itself, and to point out the advantages which will accrue by a due adjustment of the debt. But there is a wider view of the question, without the consideration of which our remarks would be incomplete. The public is indebted to the Horological Institute for promoting and perfecting the science of horology, and it, too, should do something by way of acknowledging its indebtedness. Now, it is a fact that no other nation possesses a society that equals this Institute in the amount of good it is effecting for the science of horology. If any would ask in what the benefits conferred on the public consist, we would select for answer the circumstance that the Institute has succeeded in obtaining a better and cheaper system of assaying and stamping watch cases at Goldsmiths' Hall. It has also appealed to the Board of Trade for a revision of certain commercial treaties, by which the foreign tariff on English watches and clocks will be more fairly adjusted, and has interfered in many other ways for the public good. Let these facts, then, be made known in proper quarters and let such influence as can be used in its behalf be brought to bear upon the subject, with a view of bringing about Government recognition. The Royal, the Astronomical, the Chemical, and other societies, are aided either with grants of money or with a place of meeting and offices, in both which respects the Horological Institute is at great disadvantages. It supports itself by subscriptions, donations, and the sale of its journal, and its library and meeting room are ridiculously small and inconvenient. Let us, then, urge upon Mr. E. B. Denison, its esteemed president, himself a distinguished horologist, to represent the matter in its true light, in the right quarter, and not to rest until he has obtained for it some privileges which shall lighten its burden, promote its interests, and be a recognition of the services conferred upon the people. This, with the hearty co-operation of the members, will in time place the Horological Institute amongst the foremost of the scientific societies of Great Britain.

NOTES ON OUR NAVY.

I HAVE promised to enter more into the details of what our men-of-war should be, as a great maritime nation like England requires two descriptions of ships—one to fight her battles around her own shores (the Mediterranean, or perhaps America), and the other to defend her commerce from the countless privateers which France or the United States so well know how to organize. The latter, whenever we have a little trouble on our hands with any other nation, kindly threaten to sail their rovers under our opponent's flag, a piece of disinterestedness which will meet with the attention it deserves when they think fit to put their threats into execution. I will, however, pay them the compliment to admit that in any future war their inroads on our commercial marine, by means of their privateers, will cause England more anxiety and trouble than those of France, or any other nation. Apart from the scum and rascality of Europe, which would sail under their flag, the natural lawlessness and love of adventure of a large class of the people of the United States would induce them to equip and man almost any number of vessels whose object was plunder.

I have before stated that we are paying too much attention to the thickness of the iron plating, at the expense of other qualities. The magnificent "Hercules" carries but three days' coal—too little for a ship to act offensively at any distance from a coaling port. To be thoroughly efficient for all purposes, she ought to carry eight at least. For a guard ship at any of the Channel ports she is all that can be desired, but we require such a one to be in the van at all times. There has lately been a great discussion on the superior handiness of short ships, and the consequence is that many essential points have been sacrificed to secure that supposed end; and in February last I read a leading article in the "Army and Navy Gazette," advocating shorter ships than the "Bellerophon" and "Hercules," and more power than they now have, to enable them to keep up the same speed as at present. The writer was evidently afraid that a ship so long as the "Bellerophon" would take too long in turning. Now, for many years I have handled the largest classes of ships, and I really find very little difference between one of 350ft. and one of 200ft. when you understand your profession. The writer also appears to forget that in action any ship which was required to take up a particular position would have to go over a large space of ground to reach it, thus making the enemy's vessel the centre of a circle while he ran down the circumference, so that a few turns of the screw of the former would preserve their relative positions. It is reasonable to suppose that the longer ship would in this case be the swifter, and if fitted as a ram would take the other at a considerable disadvantage if that mode of attack were contemplated. I have, in a former article, stated that a ship armed with the most formidable artillery and under the most favourable circumstances would have no chance against a well-handled ram. The rude outline of the class I would build has already been given in the MECHANICS' MAGAZINE. All guns are there shown on the upper deck between strong traverses. I do not consider that men run much risk from above, as the motion of a bursting shell is always forward when the initial velocity has not greatly decreased, and a wire rope netting stretched overhead from side to side would keep out all ordinary splinters from the masts and yards which might be shot away.

As the stability of all our ships is much beyond what is required, I should reduce it in all classes. This would enable the builder to have less breadth of beam and increased steadiness in bad weather. The horse-power, and, consequently, the weight of engines, boilers, &c., might be reduced without impairing the present rate of speed. I feel certain that a ship so constructed would be able to keep the sea in all weathers, and cross the Atlantic in a reasonable time. Now, no man can say how long a fleet would be

Digitized by Google

in reaching Bermuda or Halifax, places which must be our rendezvous, if ever we have a war with the United States. Should that evil day ever come, what we undertook to carry out must be done quickly, or our chance of success would be much impaired. In perusing the naval history of the civil war, I see no evidence of any superiority of American ships for offensive purposes. Their monitors, as sea-going cruizers, are gigantic failures. They trotted one across the Atlantic as a lure for the bellicose nations of Europe to purchase the others. Thanks to the interference of a landsman in France the bait took, and that power now possesses two of the most worthless war ships afloat, so worthless, indeed, that it will never be safe to send them to sea without convoy, and, when there, a Cunard steamer with her strong stem would make short work of both, without inflicting fatal injuries on her own hull. I am of opinion that we are aiming at too high a power of resistance in ironclads, and by this sacrifice many of the most essential qualities of a seagoing ship. I admit that one cannot have too much shelter from dangerous missiles, but, like the knights of old, we may heap on iron until the efficiency of the whole machine is impaired, and it becomes unwieldy and dangerous to its possessor. For simple coast defences put on as much as you list, but the ocean fleet should possess speed, seaworthiness, good stowage, and the power of acting together. This can only be acquired by reducing the enormous beam of our present ships, and by removing the guns to the upper deck, whether in turret or broadside, I care not, although as guns increase in size it is evident that the turret will stand a greater chance of injury from heavy shot and become disabled.

The light ships for protecting commerce should be built with more consideration for their speed than fighting qualities. It is against privateers that we must guard, and the Americans have, as I have before remarked, a wonderful facility for constructing vessels of that class. Now, what could our "Danae" and "Niobe," which are now the models for such ships, do against a few active privateers. Their top speed is not sufficient to insure confidence, and how many days' fuel do they carry? The "Icarus," "Cordelia," and others of that class, are totally inadequate for such a purpose, and would be a source of weakness in the event of a sudden war breaking out. Whenever that day comes it will neither be ironclads or monitors which will ruin our commerce, but light-built corvettes or frigates, commanded by active restless men, who will hunt their quarry in every part of the globe where a keel can float. These vessels will not be loaded with heavy guns to strain their topsides or impede their sailing, but simply carry one or two of great power, as their speed would enable them to escape from any heavy cruisers which might cross their track. I therefore hope that before long we shall possess vessels of this class with greater length than the "Niobe," and beam reduced to the minimum amount of stability. It makes one smile to read all that is said about the handiness of short ships in action; one would imagine that it was necessary to keep turning round, like a cockchafer on a string, to get the guns to bear. Such an opinion is absurd. The winner of the next naval battle will be the man who, with a clear head and iron nerve, is able to warily watch the motions of his antagonist and take advantage of circumstances, for there is no plan of naval tactics which may not be checkmated by a skilful antagonist. A captain should know exactly what his ship will do under every circumstance of wind and sea, as one may often be backed in a few minutes to a position which would take a long time to do by any other method.

It is satisfactory to find that my views are finding advocates amongst the leading journals of the day; the "Engineer" is already recommending us to pause in adding a greater thickness of iron plating to ships' sides, since the penetrating power of guns bids defiance to all armour at a reasonable distance. The "Army and Navy Gazette," which affects to publish official information, says that a ram is to be laid down this year, and the "Times" ridicules the greater number of our small vessels on foreign stations as worse than useless. In speaking, however, of that squadron which is to dash off to any part of the world at a moment's notice to uphold the honour of our flag, I want to know where the ships now are; and echo answers, where? Before this wild proposition can come to pass, ships must be constructed on the plan I have recommended; at present, the most formidable do not carry sufficient fuel to carry them by easy stages across the Atlantic, and should they start together on such a tour they would reach the goal like hunters after a hard day's run across country. No greater test of the efficiency of the fleet could be given than to make a signal, when ready for sea, "Rendezvous at Halifax, Nova Scotia."

Since my first article, in which I mentioned the rig of the "Minotaur" as not being applicable for such a ship, her rig has been altered, not, however, in the manner I should wish, or as science would point out. This vessels plunges dangerously in a head sea, if we are to credit the published reports, and the aim should be to lighten her forward, as the tendency of a vessel to scend under the influence of any given weight increases as the square when moved from the centre of motion. Now, it is evident that the weight of a heavy full-rigged mast must have a great effect when placed near the bow. If there were any commensurate advantage for so doing such a proceeding would be reasonable, but I know of none, as she will never be able to manœuvre under sail alone whatever her rig may be.

In concluding these notes, I think it right to express my admiration of Mr. Reed as a constructor; such a man would design and build ships which would be incomparably superior to any afloat, if he thoroughly understood the nature of the service on which they were to be employed. At present, all his energies are concentrated on one point, viz., to place the greatest possible thickness of iron armour-plating on the hull at the expense of the most essential qualities of a sea-going ship, a defect which at some future day will bear its fruit. X.

PHOTOGRAPHY.

DR. GLADSTONE'S NEW EXPERIMENTS ON LIGHT —USEFUL LIMELIGHT SAFETY VALVE—SMALL CAMERAS FOR TOURISTS.

At a recent Friday evening meeting of the Royal Institution, Sir Henry Holland, Bart., F.R.S., in the chair, Dr. J. H. Gladstone, F.R.S., gave an experimental lecture relating to some new discoveries of his own on the subject of light. He pointed out that the indices of refraction of liquids are lowered by increase of temperature, and, by means of a hollow glass prism filled with oil of nutmeg, he showed that the more the oil was heated the less could it bend a ray of light from the electric lamp out of its primary direction. This law holds good with all liquids. Solids, on the other hand, as they are heated, have their power of refraction very slightly increased, with the exception of crown glass, which is not optically influenced by temperature, and fluor spar, which behaves like a liquid, and has its power of refraction diminished by an increase of heat.

One optical property alone, the Rev. Pelham Dale and Dr. Gladstone discovered to be common to the solid, liquid, and gaseous conditions of bodies, namely, "the specific refractive energy," that is to say, the refractive index, minus unity, divided by the density. The most general law discovered was, that the refraction equivalent of any substance is the sum of the refraction equivalents of its constituents. The specific refractive energy multiplied by the atomic weight of the substance gives its refraction equivalent.

On these principles he pointed out that the refraction indices of some substances may be ascertained by calculation. For instance, bisulphide of carbon consists of one atom of carbon combined with two atoms of sulphur. Now, the refraction equivalent of crystallized carbon or diamond is 5, and of sulphur 16, so that the refraction equivalent of one atom of carbon (5) and two atoms of sulphur (32) united make 37. The index of bisulphide of carbon, as shown by experiment, is 3·73, and by calculation 37, as above, so it will be seen how closely the results tarry. Calculation and experiment do not always exactly agree, but are usually within a small decimal point of each other, or near enough to prove the truth of the general principle. Dr. Gladstone expressed the opinion that the double refraction of Iceland spar may be caused by the crystal being in a state of unequal tension in different directions, so as to permit light to pass more freely in one direction than in another.

In the use of large quantities of oxygen and hydrogen gases for the lime light, for photographic enlargements and other purposes, it is desirable to provide against the possibility of explosions, whether from accident, carelessness, or design. Mr. J. T. Taylor first adopted the plan of putting a light valve at the mouth of the gas reservoirs, so that the gases could flow out but could not run back if by any accident pressure acted in a wrong direction. An improvement upon Mr. Taylor's valves, which we have already engraved, has just been made, tested, and published by Mr. W. H. Harrison. The valve consists of a glass tube, 3in. in outside diameter, and 2in. long. In the bottom of this tube B B, fig. 1, the brass plug D with

FIG. 1.

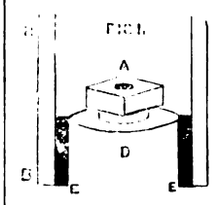

FIG. 2.

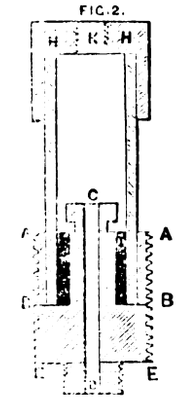

the square head A, is inserted, the plug being made air tight by the band of vulcanized india-rubber tubing E E placed between it and the glass. A sectional drawing of the whole of the valve is shown in fig. 2, where H H is a brass headpiece fixed upon the top of the glass tube with plaster of Paris, and has a screw thread at K to take a metal tube to receive the india-rubber piping. The brass plug is represented by C D, and a slip of oil-silk is tied across the orifice C, to act as a flexible valve. A B is a brass ferule, cemented on the outside of the glass tube. The outside of this ferule, as well as the outside of the broad part of the plug B E, is corrugated in circles, so that a piece of india-rubber tubing may be slipped over it, if necessary, as a further protection against the leakage of gas. This precaution, however, is not likely to be practically wanted. The small end of the plug D screws into the tap of the gasometer or gas bags. The advantage of this arrangement is that the valve has no hinge or spring to get out of order, that its working part is always in sight, that if anything goes wrong the plug can be pulled out, and the valve put right in an instant, and that it utterly prevents the gas of one reservoir from flowing into the other to make an explosive mixture.

Mr. C. D. Smith, one of the officials of Messrs. Negretti and Zambra, has written to a photographic contemporary to "rectify," as he says, "a few errors," in the description recently published in the MECHANICS' MAGAZINE, of a portable camera manufactured by that firm. As our original notice contained no errors, the letter by Mr. Smith is rather cool. We pointed out that the camera was too bulky for the pocket. Mr. Smith says it is not, but further on he states that the camera, with dark slides for six pictures, will go inside a case

Digitized by Google

9¼in. long by 5in. square. If Mr. Smith will carry a log of wood 9¼in. × 5in. in his pocket for a week, he will soon find out whether this is a convenient size for a pocket camera. The fact is, that in calling it a "pocket camera" Mr. Smith omits consideration of the dark slides and lenses whilst we included both, for a tourist cannot take pictures with the camera alone, without lenses and photographic plates. Then, he says, our description of the stand is incorrect, but as we had then never seen the stand, or described it at all, the alleged error was never made. We described some faults commonly found in portable stands, one of which faults, we learn from Mr. Smith's letter, belongs to his stand, a picture of which has since been engraved in the MECHANICS' MAGAZINE, of May 8, page 355. Stands of that description are not steady in a breeze, and, under such circumstances, will so "blurr" the lines of the picture, as to render good photography impossible. We have practically tried all kinds of portable stands for tourists, and find none more convenient or certain than one with a very small triangular top, permitting the legs to lie so close to each other that they can be carried attached to the triangle, without giving the operator the trouble of screwing and unscrewing the parts over each view. The whole point in Mr. Smith's letter lies in its closing sentence, as follows:—"The above camera and stands are now on sale at Messrs. Negretti and Zambra's, 135, Fleet-street." This fact might have been published without charging the MECHANICS' MAGAZINE with errors it never made.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

THE INDUSTRIAL PRODUCTION OF HYDROGEN—A NEW MODE OF PROCURING PHOSPHORUS—GERANOSINE, A NEW ANILINE DYE.

MM. TESSIE DU MOTAY and Mareschal have patented in France a mode of preparing hydrogen for industrial purposes. Water has been regarded by many enthusiastic people as a cheap source of fuel, and several modes of decomposing it and separating the hydrogen have been proposed. Steam has been passed over red-hot coke, by which a mixture of hydrogen, carbonic oxide, and carbonic acid is procured. The last was separated by means of lime, and the two former were then available for heating purposes. But in this case the amount of coal expended in procuring the combustible gases exceeded in heating value that of the gases produced. More recently, it was ingeniously proposed to make water indirectly decompose itself by employing water-power to drive large electro-magnetic machines and using the stream of electricity generated to decompose water, and thus furnish a continuous supply of gaseous fuel. In this case also the amount of fuel obtained is altogether insignificant when compared with the force expended in procuring it. Thus the question has been left until now, and although it cannot be said that the inventors named above have solved the difficulty, they have perhaps, as the phrase goes, made a step in the right direction. Their process is really the decomposition of the vapour of water by red-hot carbon, but they do not use steam ready generated, and thus save the expenditure of coal in one furnace. They take alkaline or earthy hydrates, mix them with coke-dust, and heat the mixture in retorts. The heat expels the water from the hydrates, and the vapour coming in contact with the carbon produces hydrogen and carbonic acid. The latter is removed by passing the mixture over an alkaline carbonate, which is thereby converted into a bicarbonate, and the hydrogen passes on. The bicarbonate, when re-heated, gives up the extra atom of carbonic acid, and the neutral carbonate is regenerated for another operation. Another mode of procuring pure hydrogen is to drop hydrocarbon (petroleum oil) upon lime heated to cherry redness. In this case, they say, pure hydrogen is set at liberty, and carbonate of lime is formed, but the source of the oxygen necessary for this is not obvious. There is an apparent economy in the first process of these inventors, but still the hydrogen will be a very expensive fuel, while, for lighting purposes, it would require to be "carbunetted," which would make it dearer than coal gas. The inventors evidently do not realize all the obstacles in their way. Hydrogen, it is true, weight for weight, gives four times the heat of coal; but hydrogen is so extremely light, that, bulk for bulk, it is calculated that the gas will give only one five-thousandth part the heat of coal. The loss in storing and distributing, too, would be enormous. We mentioned last week the extraordinary facility with which hydrogen passes through cast-iron, which shows what would happen in gas-holders and pipes. We fear the day is very distant when hydrogen will be directly available for fuel, and can only recommend these processes to the attention of the Aeronautical Society.

Another new process which recommends itself by an appearance of simplicity is one for the manufacture of phosphorus. Silica, it would appear, has the power of displacing phosphoric acid from its combination with lime, and the acid is decomposed and phosphorus set free by contact with red-hot carbon. The inventor, therefore, mixes apatite with twice its weight of sand or ground flints and some charcoal, or animal charcoal with the silica, and heats to orange redness, when phosphorus distils over, and may be collected in the ordinary way. If this process answers, it is a decided improvement on the old mode of procuring phosphorus.

The various shades of red procurable from the aniline dyes are not yet, it seems, exhausted. We find another new one under the name of *Geranosine*. It is prepared by making first a solution of one kilogramme of any salt of rosaniline in 1,000 litres of boiling water; this solution is allowed to cool to 45deg. Centigrade. Another solution is made by first mixing 4½ kilogrammes of binoxide of barium with 35 litres of cold water, and then adding 10 kilogrammes of sulphuric acid. The two solutions are then mixed. The mixture instantly becomes of a lemon-yellow colour, and in a short time is nearly colourless. It is then filtered to separate the sulphate baryta. The filtered solution is afterwards gradually heated, and as the boiling point is reached it assumes a red colour, which arrives at its greatest intensity after two minutes' boiling, and is then ready for dyeing. The shade of colour produced is that known as *ponceau*, and in brilliancy it nearly equals the same shade produced from cochineal. The use of acid brightens it; ammonia discharges it. The composition of geranosine is not given, but it is evidently an oxidized product of rosaniline. When precipitated from its solution the new compound is soluble in alcohol, and partially so in acids.

ON CERTAIN POINTS IN THE MANUFACTURE OF MALLEABLE IRON, WITH SPECIAL REFERENCE TO THE RICHARDSON PROCESS.*

By MR. ST. JOHN VINCENT DAY, C.E.

SINCE the year 1784, when Cort introduced the process of puddling, there has not been any really great advance made in improving the general results obtainable from the conversion of crude or pig into malleable iron in the puddling furnace until very recently. By no means do I here intend to arrogate for Cort the raising of the puddling process to its present state of comparative efficiency, for no matter how very imperfect that process yet remains, still it is well known that the results produced by it were not generally to be depended upon until long after the inventor's unfortunate career terminated with his death—indeed, the first quarter of the present century had nearly passed away ere the puddlers' manipulations could be relied upon continuously, and it is highly probable that even then the uncertainties of production would not have been largely removed but for the careful attention of some of the North of England ironmasters who perceived a wide field opening up for a high class of manufactured material in the iron canal and river boats, and railways then coming into vogue; and, later still, in supplying that required for our great tubular and girder bridges and lines of Transoceanic steamships.

During the present century, however, innumerable attempts at improving the process have been made at home, on the Continent, and in America, still with no good effect generally; indeed, the value of what has been done, taken on a broad, practical, and, therefore, commercial basis, has been extremely small. It is, however, perfectly true that the failures which have been encountered have increased our stock of information as to the peculiarities, or rather specialities, of the compound we have been treating in the puddling furnace, and in this particular view recorded failures, when accompanied by a faithful declaration of what took place, are of the highest importance. As a very striking instance, I may allude to the most recent and gigantic failure that has, and, probably, ever will occur in a future time in the metallurgy of iron, I allude to the impossibility of making good commercial iron out of the ordinary ores of this country by the Bessemer process. Mr. Bessemer has himself on several occasions openly confessed that he could not succeed in making good malleable iron by his process purely on account of the impossibility of removing sulphur, but more particularly phosphorus, in the converter; his early experiments showed distinctly that whilst the highly oxidizing effect of the blast injected into the converter was most efficient in removing carbon and silicon and some of the lesser impurities, still the phosphorus and sulphur remained untouched, the immediate consequence of which has been that his process has never come into practice for making iron from the ordinary run of British ores—by far the larger portion of which contain notable quantities of these two elements, of which phosphorus is the greater enemy, its presence rendering the iron coal-short, whilst sulphur has the opposite effect of rendering it red-short.

I have before referred to Cort's process, and prior to directing attention to the more immediate subject of this paper it will be an advantage, in a casual way, to refresh our memories by considering what has been done successfully towards the improvement of puddling since his day up to the present time. Before doing so, however, I wish to remark that although the invention of puddling is usually ascribed to Cort, there exists very grave reasons for withdrawing from him the origination of it, as a reference to the specification of a patent granted to Thomas and George Cranage in 1766 will easily show.

The Messrs. Cranage were workmen employed at Colebrookdale, and it is recorded that puddling was practised there prior to Cort's invention, for when the latter applied to Mr. Reynolds, at that time the manager of the works, he replied in his Quaker tongue, "If thou wilt come with me to the works I will soon show thee the thing done." Cort went, and, at the command of Reynolds, Tom Cranage made a puddled ball in their presence It appears, however, that the process was not carried out on a large scale at Colebrookdale until after Cort had been there, so that it is probable some practical difficulty existed in what the Brothers Cranage had done. The fact would show that to Cort must unquestionably be attributed the high distinction of being the perfector rather than the inventor of the process called "puddling."

The process of puddling, too, was very completely set forth in the specification of Peter Onions in May, 1783, about a year prior to the date of Cort's patent; indeed, it appears extremely probable that ironmasters at that period, hearing of the partial success of the Cranage process, had begun to set themselves the task of perfecting it, hence the inventions of Onions and Cort so close one upon the other. The question of Cort's invention has, however, been so frequently discussed elsewhere, that I need not further allude to it here; the deplorable tale connected with it is so well known to us all that it need not be again enlarged upon.

The next great step of improvement that presented itself was that of Mr. Samuel Baldwyn Rogers, of Nante-y-Glo, who substituted the "iron bottom" for Cort's sand bottom. This, like every other really valuable discovery, was condemned by the Welsh ironmasters, and after it had been derided at by Mr. Hall, of the Rhymney Ironworks, Mr. Hill, of the Plymouth Ironworks, Mr. Homfray, of Tredegar, Mr. Crawshay, of Cyfarthfa, Mr. Forman, of Pendarron, and others, it was ultimately tried at Ebbw Vale by Mr. Richard Harford, who, on discovering its advantages about or shortly after the year 1818, adopted it, since which time others followed his course until wherever puddling is now practised the cast-iron bottoms are used. Rogers' fate as an inventor was as sad as his unfortunate predecessor Cort: both lived for years, and ultimately died, in absolute penury.

The "boiling process" was the next great stride; it is generally attributed to Mr. Joseph Hall, of the Bloomfield Ironworks. "Boiling" is produced by charging certain oxidized compounds of iron on the puddling hearth, from which, as soon as melted, some of the oxygen begins to separate, and, uniting with some of the carbon of the iron, forms carbonic oxide, the presence of which may always be detected by the well-known bubbling about of the metal, attended with endless escaping jets of

* Read before the Institution of Engineers in Scotland.

Digitized by Google

blue flame. Until the charge is melted the solid oxide is covered with liquid cinder, composed in great part of protoxide of iron; this being combined with silica, constitutes a silicate of protoxide of iron, which, after melting, combines with additional silicon in the pig, and some of the iron of the charge forming the tribasic silicate of protoxide of iron ($3\,Fe\,O, Si\,O^3$), without the presence of which the process of puddling could not be carried on, this silicate possessing the peculiar property of not further oxidizing iron at the most exalted temperatures employed, and being easily separated from it, so that although the granules of iron in the puddling furnace after the boiling stage is over, and the temperature of the furnace is lowered, are lying scattered about in it, still, on being pressed together, they unite, the fluid silicate being easily squeezed out from between the surfaces of contact by means of the puddlers' balling rod; whilst that portion which still clings to the iron after the balling is over is what we see extracted from the mass under the shingling hammer and between the roughing rolls. Boiling, then, along with the use of roasted tap cinder, or "bull-dog," as it is generally termed, constitutes the last great step in the chemistry of the process since the time of Cort.

In the mechanical operations of puddling and in the construction of the furnace several attempts towards improvement have been and continue to be made. In the furnace itself the use of water-troughs through the bridge, and in some cases forming the sides of the puddling hearth, have come into practice, but their value in a sense of effecting ultimate economy, for several reasons, appears to me to be very questionable. Double furnaces, too, have been tried—that is to say, furnaces capable of containing a double charge of metal, and with a puddler working at both sides, but it is a striking fact that they are being given up, and the old-fashioned single furnace, still obtains. I am informed by some of the Scotch ironmasters, that the iron from the double furnace is never so good as from the single furnace, and the charge is generally longer in melting. The chief object intended by their introduction was a diminution in the fuel consumed per weight of iron manufactured; this to some extent is obtained, and probably herein consists the reason why the charge is longer in melting. Considerably less than twice the weight of fuel has to melt exactly twice the weight of iron, but the furnace is not twice as large, generally not more than 10in. or 11in., or less than a foot broader than a single furnace, the height and length being the same, so that the space occupied by the heat from the fuel in the double is nearly proportional to that of a single furnace, but as the charge of iron therein is proportionately very much greater than the fuel, it follows that a longer time of melting should obtain. At least, the question having been submitted to me for consideration, this is the only reasonable view I have been able to arrive at.

As to the quality of the iron produced in double puddling furnaces being frequently inferior and of indifferent nature, I cannot account for that in any other way than by looking at the cause as inherent in the difficulty of geting the two puddlers to work the two portions of the charge in concert with each other. It is almost certain that one will work his part of the charge more or less than the other, thus producing iron in the same furnace necessarily of dissimilar quality. However, the cause of inferiority of double puddling furnaces against single is a question by no means thoroughly investigated, and it forms a topic which I think this Institution might discuss with obviously great advantage. It is probable that when a perfect system of mechanical puddling is devised, that then, provided such is effected by the movement of rabbles, double furnaces may be generally adopted, as certainty of similar action of the two instruments may then be insured by their being placed under the control of properly arranged machinery.

Speaking of mechanical puddling, numerous expedients have been tried but with no practical success, generally, in Great Britian. At Dowlais, almost every hitherto conceivable means for doing away with the puddler has been resorted to, but with what result? I have no doubt that many of the members of this Institution will remember the singular paper read by Mr. Menelaus to the Institution of Mechanical Engineers who met at Paris during the past summer; a paper I say singular, because it was so very dissimilar to what papers read before such institutions usually are. We generally and naturally find ourselves and others recounting our and their successes, but here Mr. Menelaus, in the most laudable manner has placed on record everything that has been done at those gigantic works under his control—all of which has ended in failure, and he has not attempted to hide the failures either.

At Dowlais, too, Mr. Anthony Bessemer's revolving puddling furnace has been used, but it has failed, as well, I believe, the injection of steam by a tube or plast-pipe, according to Mr. Nasmyth's plan; also air and steam combined, after the process of Guenyveau, and, I am told, even the introduction of a blast of air alone through a blast-pipe, still all ended in absolute failure.

The most successful experiments in connection with mechanical puddling that have come under my notice were those conducted by MM. Dumeny and Lemut, at the Clos-Mortieur Forge, in the commune of St. Dizier (Haut Marne). I will not now take up your time in describing the various mechanical arrangements they have adopted, but merely state that I some time since received a report in which they assert the practical results of their apparatus are—1st. That the consumption of fuel is greatly reduced per ton of metal produced; 2nd. The work is accelerated and the production of the furnace increased, from which economy in the general and working expenses has resulted; 3rd. The obviating the necessity of workmen in stirring the cast-iron lowers the price of labour, whilst at the same time it enables the wages of the regular puddler to be augmented, although their labour is lightened; 4th. The waste is about the same as in the system of ordinary puddling, which is equivalent to saying (in others words) that the yield is the same as under the hand system; 5th. The improvement in the quality of the iron is undoubtedly the effect of the mechanical puddler.

Having now drawn a sketch of puddling from its earliest date down to the present time, I proceed to direct your attention to some remarkable facts connected with a new process, viz, "The Richardson Process," which I am sure will be of great interest, as it is of the gravest importance to nearly every member of this institution, being particularly interesting because the chief practice with it has taken place in the neighbourhood of Glasgow. Of this process and its results some facts have lately appeared in the engineering journals, and I am happy to be able to state that, in the views which I originally formed, my conclusions have since been fully borne out by the remarkably accordant results we have obtained at the Glasgow Ironworks, but more particularly at Parkhead Forge.

Generally, I have no doubt the members of this Institution are aware in what the "Richardson Process" consists. I will presently, in few words, explain its chief feature, but first wish to mention what has been previously attempted in a similar direction. Reuben Plant was among the first to introduce blasts of air and steam into the puddling furnace, and, provided he had continued his experiments to completeness, there is little doubt but that what is now known as the "Richardson Process" would have been an established mode of manufacture twenty years ago. As it is, to Mr. Richardson, who was associated with Plant at that time, the credit is due of having made the first recorded experiments of blowing air below the surface of fluid pig-iron; when he obtained that peculiar series of changes which we daily see produced in the Bessemer converter. Had Mr. Richardson continued the blowing of air long enough there is no doubt he would have succeeded in making worthless malleable iron, as Mr. Bessemer has done, through not being able to eliminate the sulphur and phosphorus. Other circumstances, as Mr. Richardson informs me, interfered, that a stop was put to the prosecution of the experiments, and thus it became reserved for Mr. Bessemer to follow up that same line of triumphant investigation by which he has immortalized his name—the process for making "Bessemer steel."

At Dowlais, in particular, as well as it Cwm-Avon Ironworks, in Glamorganshire, blasts of air were blown into the metal on the puddling hearth, but for a very different object to that which the "Richardson Process" seeks to effect. In all the experiments, as I am informed, that were made prior to Richardson's, the blowing was continued for a long time after the iron had been brought to the boil. Now, it is perfectly clear that in an ordinary furnace such continuous pouring in of oxygen would boil the metal to such an extent that it must run rapidly away with the slag from the stopper-hole, and being continued long after the desilicatization and decarburization of the charge were effected, would oxidize the iron to an enormous extent, thus diminishing the yield so much as to reduce the ironmasters' profits to a degree that could not be tolerated. But these are not all the defects of such a constant in-pouring of oxygen. The powerful attack upon the carbon and silicon, and after that the combination with the iron itself, must raise the temperature of the furnace to such an extent that the bricks usually employed in the construction of such furnaces would melt away, and the life or duration of the furnace would therefore be reduced to a comparatively brief existence; and I may here remark what is a singular fact that although persons originally engaged in such experiments did not discover a remedy for this evil, it is well known that for puddling furnaces common soft bricks are employed, the higher limit of temperature employed for puddling not requiring the use of the harder and more durable kinds which are used for furnaces wherein the temperature ranges higher. The same defect of the more rapid destruction of the roof has been met with in recent processes for making steel, but that has been entirely overcome by the use of harder bricks and a higher roof.

(To be continued.)

THE NATIONAL ARTILLERY ASSOCIATION.

THE council of the National Artillery Association has just drawn up its programme for the ensuing prize meeting at Shoeburyness for the "great gun" prizes, contributed by Her Majesty, the Prince of Wales, Lord Longford, the National Rifle Association, and the various artillery corps. The work of the meeting will this year be compressed into one week, and the camp at this noted school of artillery will be for the volunteers who visit it and take up their quarters there not only a camp for artillery practice, but one for general instruction in military duties and discipline. A new feature will this year be introduced by a movable target being arranged at the 1,000 yards' range, to be fired at with the Armstrong rifled ordnance; the target will be moved by aids at the disposal of the Royal Artillery, at the rate of seven miles an hour, and the competitors in the one competition will fire as many rounds as possible in a given time. In the general competitions the council hope to give as many prizes as will enable the batteries in camp to have three competitions a day. The prize meeting will open on August 3 At a meeting held a few days ago by the council when Colonel Harcourt, Lord Hardinge, Colonel Cox, Major Innes, Captain Darby, Captain Sankey, Captain Staddert, Captain Rutley, and Mr. A. Beattie were present, it was agreed that Lord Hardinge and Captain Welby Pugin should form a prize committee. The Association, by the support it has received from the most active volunteer artillery corps and from the National Rifle Association, has nearly overcome the great monetary difficulties thrown upon it by the heavy Government charges for camping material.

THE INSTITUTION OF CIVIL ENGINEERS.

AT the closing business meeting for the present Session, held on Tuesday, the 19th inst., Mr. Charles Hutton Gregory, President, in the chair, nine candidates were balloted for and duly elected, including, as members, Mr. Thomas Login, F.R.S.E., executive engineer of the the first class in the P.W.D. of the Government of India; Mr. William Teasdel, resident engineer, Great Yarmouth Port and Haven; and Mr. Edward Williams, general manager, of the Mines, Collieries, and Iron Works of Messrs. Bolckow, Vaughan and Co., Middlesborough; and, as associates, Mr. Henry Samuel Ellis, Exeter; Mr. Charles Higgins, surveyor, Islington; Mr. William Hurst, Paddington; Mr. Samuel Joseph Mackie, Bayswater; Mr. John Palmer Smythies, assistant engineer, Furness and Midland Railway; and Mr. Arthur J. Whalley, Monte Video. It was also announced that Mr. Nicholas Charles Szorelmey had been admitted a student. The total number of elections during the session 1867-68 has been 150, viz., 45 members, and 105 associates. The register of the Institution now contains the names of 16 honorary members, 641 members, 914 associates, and 123 students, in all 1,694, as against 1,449 of the various classes, at the same date last year, including, at that time, 20 honorary members, 591 members, 834 associates, and 4 graduates. The class of students has been created during the sessions just concluded, to take the place of the old Graduate Class, which is now abolished.

SCREW PRESSURE PIPE JOINTING MACHINE.

BY MR. H. T. HUMPHREYS.

FIG. 1.

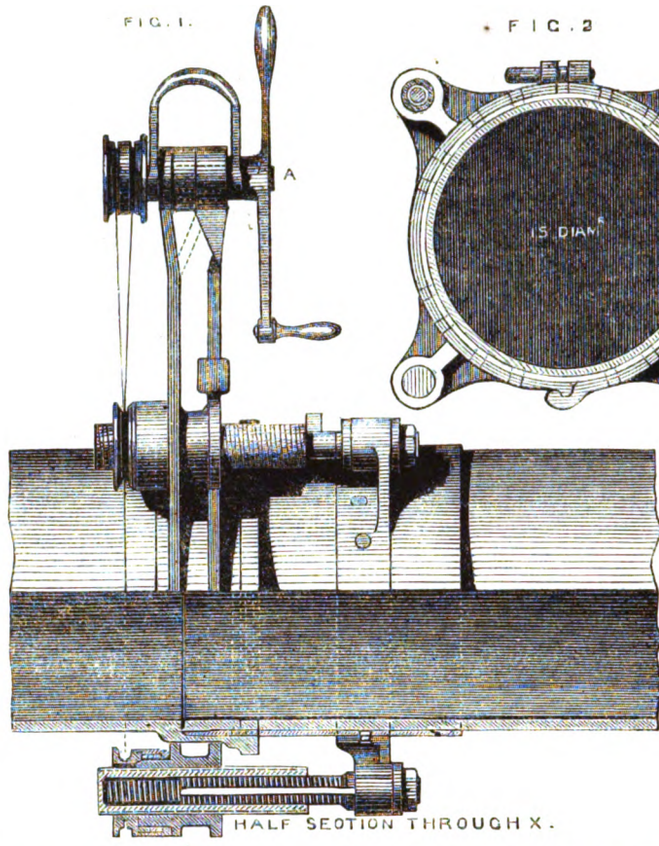

FIG. 2.

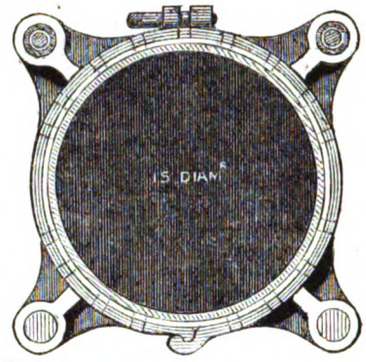

FIG. 3.

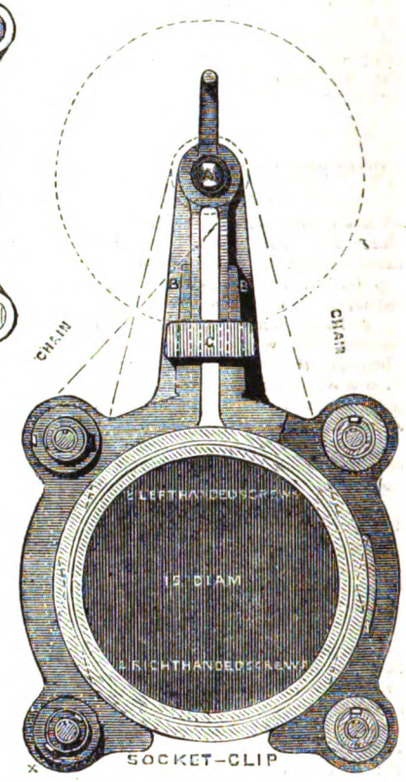

SCREW PRESSURE PIPE JOINTING MACHINE.

THE accompanying engraving shows a ready and simple means of jointing pipes with cold lead, pressed in by machinery, instead of with molten lead, "set-up" by hand. The machine has been invented by Mr. H. Temple Humphreys, Westminster. By using cold lead in the form of a rolled rod or wire, served round the joint after the fashion of a rope, and then pressed with a great pressure until it becomes ductile enough to fill every crack and cranny of the socket, a perfect joint will be made, and at the same time the following advantages over the old process obtained:—First, the possibility of jointing under, or partially under water, in a wet soil and trench, where the pumping often becomes a heavy item, before the molten lead can be run into the socket. Secondly, a saving of coals, and oxidation of lead, together with waste through spilling the same; the repeated removals of furnace, the cartage of coals, and the services of the furnace attendant, are also all rendered unnecessary. Thirdly, the manufacture of a better and more uniformly reliable joint, in a shorter time, by machine, than can be done by the same number of hands with setting-up hammers.

The process is as follows:—The joint to be made is clipped round the socket with a socket clip, which hinges at A, and clips by means of the wedge blades B B, and wedge block C, which is driven down the wedge blades by one blow of a hammer. A sufficient amount of rod lead wire, unrolled from a hank of wire off a drum upon a pair of wheels, is now coiled round the spigot, and pushed into the joint by hand as far as it will conveniently go. A ring of wrought iron plates, in segments of suitable sizes and thicknesses, corresponding to the varying thickness and shapes of the joint to be made, having been placed round the spigot, the spigot clip is then put on over this ring, and the four differential screws entered into their respective nuts on the socket clip, for which purpose they are each made a little shorter than the first entering screw in order to engage threads consecutively, and not all at once. By turning the handle, the light pitch chains and pulleys drive the two right and two left-handed differential screws uniformly alike, quite independently of each other, or of any movement of either half of the socket clip in opening and clipping round the socket, so that the machine is always ready for use, as soon as adjusted to the pipe to be jointed. The revolution of the screws forces the ring of wrought iron dies into the joint, with a very great pressure, proportionate to the sizes of the pitches of the screws; this squeezes the lead like so much clay into the closest contact with the surfaces of the pipes, and by simply repeating the above operation, after coiling more lead wire round the spigot, the requisite depth of lead is obtained, and a sound and rapidly made joint insured. The joint may either be yarned or not, as found most convenient, but in either case the yarn can be forced in by the machine, and, in order to increase the speed of the dies for this purpose, or for pressing the first strands of wire into place—both of which operations do not require the exertion of the whole power of the screws—keys are provided to insert between each differential pair, thus making them revolve together, and, consequently, to resemble a simple screw. Arrangements have been made, we believe, whereby these machines can be produced at a price sufficiently low as to render their use most economical upon any contract for laying gas or water mains over half a mile in length.

COMBINED ANVIL AND PRESS.

THE invention illustrated in the accompanying engraving consists in combining with an anvil for forging and other smithing purposes a power press, punch, and shears for convenience in cutting metals. It is the invention of Mr. J. E. Emerson, of New Jersey, and has just been patented in England. Fig. 1 is a longitudinal vertical section through the improved anvil, and fig. 2 is a perspective view of the combined anvil. A is the anvil; B is a horizontal shaft, having a pinion C keyed upon it, and having a square head on each end, which is received in a corresponding opening in the end of the lever D. The pinion C gears into the toothed segment E on the long end of the lever F, which has its fulcrum at G. At the short end H of the lever there is also a toothed segment, the teeth of which gear into those of the rack K, which moves vertically in guiding recesses, and carries at its lower end a punch L, which may be of any form, to act as a slotter or a gummer for saws, or for any punching or pressing purpose, or it may be used for a former. The die L' for the punch is in a block let into a groove in the bed of the anvil, and is dovetailed on one side, and secured by a key M driven between the other side of the groove and the block. The sides of the groove are made parallel, while the block is made wider at one end than at the other, and the key has a corresponding taper.

FIG. 1.

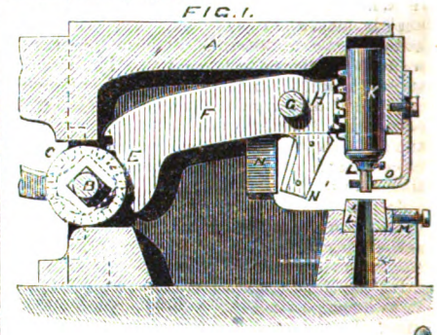

FIG. 2.

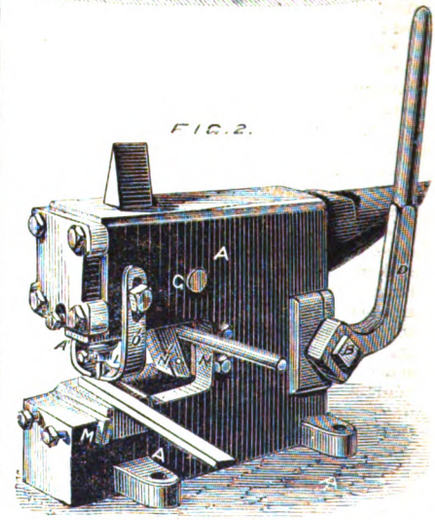

The metal, after being punched, is cleared from the punch by the device O which is common to punching machines, and consists of a fork having its prongs horizontal, and one on each side of the punch a short distance above the die, and secured by a set

Digitized by Google

screw to the end of the anvil. One of the blades N of the shears N N¹ is secured to one side of the recess which contains the lever F in the body of the anvil, and the other blade N¹ is secured to a projection from the short end of the lever F, so that its edge shall form an angle with that of N in the manner common to shears for cutting metal. When the lever D is vibrated the pinion C on the shaft B causes the lever F to vibrate and give motion to the punch with great power by means of the segment H and rack K. The same movement of the lever D also causes the shears to perform their work through the medium of the pinion and segment E in the lever F. The workman at the anvil thus has no occasion to lose time and heat in seeking to have these offices performed, oftentimes at some distance from the forge.

ON THE CONSTRUCTION OF STEAM BOILERS.

IN noticing lately the report of Mr. Henry Hiller, the chief engineer to the National Boiler Insurance Company, we expressed our intention to notice further Mr. Hiller's remarks on the construction of boilers, and we now redeem our promise. A large number of the boilers proposed for insurance are so weak in construction, or otherwise so defective, that some general remarks, based on extensive experience of the construction and working of all kinds of steam boilers, will doubtless be found useful to many owners and makers. Of the numerous varieties, none are more generally used than the Lancashire, or cylindrical two-flued, and the Cornish one-flued boilers, and where these are well constructed, properly fitted up, and carefully attended, their performance is generally satisfactory. There are various modifications of these forms, some of which are valuable. In designing such boilers, excessive length as compared with the diameter should be avoided. Long boilers strain considerably, and frequently give great trouble by leakage at the riveted seams. A fair proportion is when the length is about three and a-half times the diameter. The staying of the end plates, and the attachment of the flue tubes to the ends, should be so arranged that the tube may expand freely, unless there be some special arrangement in the form of the flue tubes to attain the same object.

Many boilers, otherwise well made, have given considerable trouble by leakage and fracture, owing to the severe strains of unequal expansion: to which their rigid construction exposed them. In some of the boilers inspected, the ends were so heavily stayed, and so rigid, that considerable leakage, and occasionally fracture at the ring seams of the lower part resulted. In others, the staying was so slight, that the ends were bulged outwards, and serious risk of explosion thus occurred. Flue tubes should never be stayed to the shell, but be attached at the ends only. Many boilers have given serious trouble through being thus stayed. The shell should be made quite circular, and the longitudinal seams, which should break joint, be so arranged that, when the boiler is set, all those below the water line may be accessible for examination in the flues, and be clear of the brick seatings. Many makers now double-rivet these seams, thus materially increasing their strength, and when the work is well performed, reducing liability to leakage.

Flue tubes are now constructed in various ways, some makers preferring to use thick plates not strengthened in any way, whilst others prefer comparatively thin plates; but by flanging them at the ring seams, or by welding each ring of plates, and connecting them by solid T-iron hoops, form a much stronger and more reliable flue tube. The liability to leakage, fracture, and excessive expansion, is thus much reduced; as the heat is more freely transmitted through the thin plates. The cross tubes and water pockets introduced by some makers in that part of the flue tubes beyond the furnace bridge, are of great value, chiefly from the manner in which they improve the efficiency of the heating surface by the diversion and breaking-up of the current of the gases; whilst they much increase the strength of the tubes to resist collapse. All large tubes exposed to high pressure should be strengthened by some of the means described. Where the tubes are formed with the ordinary lap-joints, the longitudinal seams should break joint, as a tube thus made is much stronger than where those seams are in line, and at the furnace end all longitudinal seams should be below the fire-grate level.

The plan of forming tubes with the plates laid longitudinally in narrow strips is very objectionable, as the tube cannot be made so circular, and the seams above the bars are injured by the action of the fire; whilst such tubes are much weaker than those made in the ordinary manner. Multitubular boilers should, as far as practicable, be so constructed that every part of the interior may be accessible for cleaning and examination; and it would be a great improvement if those of portable and locomotive engines were so constructed that the tubes could be drawn without difficulty, so as to allow occasional inspection of the internal surface of the plates. External flues are necessary to stationary cylindrical boilers of this class; otherwise the lower seams are strained, and become leaky through excessive unequal expansion of the boiler. Plain cylindrical externally-fired boilers, with egg or saucer-shaped ends, are preferred by some owners, chiefly on account of their simple form. Such boilers can never work so safely as a properly constructed internally-fired boiler, as they are so liable to fracture at the seams over the furnace, through the excessive alternate expansion and contraction to which they are exposed. The application of stout longitudinal stays would add materially to the safety of such boilers.

A large number of cylindrical vertical boilers are used in various ironworks. These boilers are generally heated from the puddling or similar furnaces, the heat first entering the external flues, and passing thence by an internal descending flue-tube to the chimney. They are especially liable to starting and fracture of the riveted seams opposite the furnace necks, owing to the intense heat at that point; and where the feed water deposits much sediment the solid plate is sometimes fractured. To avoid this liability, the part referred to should be protected by a screen of brickwork, or the boiler set at a higher level, that brickwork may may be so arranged as to spread the heat before it reaches the boiler. The bottoms of these boilers are frequently quite inaccessible for examination, and serious corrosion may go on unknown to those in charge. If the boilers were supported by brackets at the sides, or by wrought-iron plate standards riveted to the bottom, so that a thin wall of brickwork would suffice to form the flues, the condition of the plates could be occasionally ascertained without much difficulty.

As the safety of boilers depends so much on the sufficiency and condition of their fittings, a few remarks thereon will be useful. It is well to have two safety valves to each boiler as a check upon each other; one of them should be a deadweight valve, loaded externally, and the other a lever weight valve, or a compound valve, which would allow the steam to escape if the water were allowed to fall below the proper level. Safety valves are frequently met with the levers of which are of such length, that the usual working pressure for which the boiler was made, would be much exceeded if the weight were fixed at the end of the lever. The weight should always be calculated and adjusted to hang at the end of the lever.

All boilers should be provided with correct pressure gauges, for the guidance of the attendants. The glass gauge is undoubtedly the best and most reliable water gauge, and it is a good plan to attach two gauges to each boiler. Where floats are used, there should be two, one of them fitted with an alarm whistle. Boilers with internal tubes should always be fitted with glass gauges. Fusible plugs should be attached to the furnace crowns of all internally-fired boilers. The feed regulating valve, which may be constructed to act also as a back pressure valve, should always be placed at the front end of the boiler, within the reach of the attendant, and where boilers work in connection, each should have a back pressue valve attached. The feed water should be delivered (a few inches below the surface of the water in the boiler, and above the level of the tube crowns) in a horizontal direction, or by means of a horizontal perforated pipe. Where the feed is delivered near or at the bottom of the boiler, it cools and contracts the lower plates, whilst those of the upper part are heated and expanded by the steam, frequently (especially in boilers rigidly stayed) causing fracture at the ring seams at the lower part of the shell. It is always preferable to heat the feed water before it is forced into the boiler.

The blow-out tap at the bottom of the boiler should be so placed that it may be examined at any time, and so that any leakage thereat would be at once noted. Valves should never be used, double-gland taps made altogether of brass are far preferable. Stout seatings with planed joint faces suitable for each fitting should be riveted to the boiler. All manholes should be strengthened by a faced mouthpiece, riveted to the boiler, so that the joint may easily be well made, and leakage with corrosion be avoided. Steam domes are unnecessary on stationary boilers; a perforated pipe placed in the upper part of the steam space is quite as efficient to prevent priming, and the boiler is not weakened. Where domes are preferred, they should never be of large diameter, and the shell plates inside them should not be all cut away.

The setting of stationary boilers is too often entrusted to men quite ignorant of what is necessary for their safe and efficient working, and Mr. Hiller has frequently had to point out serious errors in plans prepared by engineers and others, whose mistakes probably arose from a want of practical experience of the working of boilers. When boilers are about to be set, special care should be taken to thoroughly drain the ground, that no dampness may exist in the flues to cause corrosion of the plates. All the flues should be quite large enough to allow a man to pass through, so that every part may be accessible for examination. Midfeather seatings are very objectionable, and no boiler should be so set except those of very small diameter, and in such cases, thick but narrow iron plates should be placed on the top of the brickwork to protect the boiler. Cylindrical boilers, internally fired, should be set on side walls, the boiler resting on fireclay blocks made for the purpose, and so shaped that when built in place the bottom of the side flues may be much lower than the point where the boiler rests on the blocks. If the blocks be properly fitted to the plates, that the bearing thereon may be equalized, the total breadth of both side walls where in contact with the plates, need not exceed one inch for each foot of diameter of the boiler. The top of the side flues should be level with the crown of the flue tubes.

All boilers should be roofed over to protect them from external moisture, otherwise the sides in contact with the flue brickwork will be weakened by corrosion. Where flues are properly arranged as described, no serious corrosion could exist in the seatings, which could not be detected on a careful examination by a trained inspector. The laws for the prevention of smoke are now being enforced in many districts, but boiler owners should be cautioned against too readily adopting any form of apparatus which may be pressed upon their notice, as many are unnecessarily complicated and expensive.

It frequently happens that good boilers are injured and serious risk is incurred through neglect and carelessness. Where the feed water contains much sediment, and no cleaning apparatus is in use, frequent internal cleaning is indispensable, or the plates may become overheated and injured whilst the efficiency of the boiler is reduced. The external flues are in many cases allowed to become almost choked before being cleaned, and the boiler plates so thickly coated with soot, that a wasteful consumption of fuel is the result. Some firms, on the other hand, clean their boilers thoroughly about once a month, and are thereby considerable gainers, as the efficiency of the heating surface is retained, whilst any defects are at once discovered and made good, which if neglected might entail expensive repairs, or even lead to serious disaster. When boilers are being re-started after stoppage, they should be heated very gradually so as to avoid as much as practicable the severe strains of unequal expansion, and when at work the feed supply and the firing should be as steady and regular as possible. Frequent and extreme alternations of pressure, especially with high pressure boilers, or irregularity of any kind is most objectionable and sometimes really dangerous.

Steam users are strongly cautioned against the purchase of second-hand boilers. Many instances have come under notice where such boilers have required very extensive alterations and repairs, costing nearly as much as new ones, to which they were, after all, much inferior. Where it is proposed to purchase old boilers, a thorough inspection should be made by some person of special experience in such matters, whose report would be a reliable guide to the purchaser. In constructing new boilers the very best materials and workmanship should be employed. Low priced boilers made with inferior material and workmanship are unreliable, and as a defective boiler must be a source of annoyance or danger, and the consequences of explosion are frequently so terrible, it is evident that in no case is special care more necessary than in the construction and fitting up of boilers.

A REMARKABLY steady proportion is maintained in England and Wales between the number of males and females born each year. That proportion, with hardly any variation in a long period of years, is 104 males to 100 females.

EXCAVATING APPARATUS AT THE CLYDE BRIDGE WORKS.

MILROY'S EXCAVATOR.

A RAILWAY bridge of some magnitude is now in course of erection at Glasgow, for carrying the City of Glasgow Union Railways over the River Clyde. The bridge, which is on the wrought-iron lattice girder principle, will consist of five water spans, each 75ft. in the clear, and two land spans of 65ft. each. The girders will be 8ft. deep, and the bridge will be laid with a double line of way. The girders will rest upon granite columns, and the abutments will be of masonry. The superstructure will be carried on cast-iron cylinders 8ft. 4in. in diameter, some of which have already been sunk to a depth of 85ft. through the sand down to the solid rock which forms the bed of the river. When down to the necessary depth, the cylinders are filled in with concrete to about the ground level; the water is then pumped out and brickwork is built up to high-water level, at which point the granite columns commence. The process of sinking the cylinders has been shortened and the operation greatly facilitated by the adoption of an excavating apparatus, the invention of Mr. John Milroy. This apparatus is shown in the accompanying engraving, in which fig. 1 represents a side elevation, partly in vertical section, of the principal part of the machine, which is termed the excavator; fig. 2 being a plan view. A series of spades or digging and lifting blades *a* are hinged to an octagonal iron framework *b*, into which they exactly fit when closed. The spades are hinged to the outer side or rim of the frame, and are formed with sides projecting inwards, which enable them to take better hold of the earth. When the apparatus is being lowered over the spot to be excavated, the spades are open, and hang in the position shown in fig. 1. With the spades hanging thus, the apparatus is lowered as far as it will go, and the spades having entered the soil are drawn inwards through the ground each into its own opening in the frame, bringing the earth with it. The frame and spades thus brought together form a close vessel, and in this condition the apparatus is drawn to the surface full of the soil. To prevent leakage and to make good joints, strips of india-rubber are attached to the under side of the inner octagonal portion of the framework, and the T-iron arms connecting the inner and outer framing. Against this india-rubber the edges of the spades press, and, when working in soft soils, leakage is thus prevented.

We now come to the working of this apparatus as carried out on the Clyde Bridge works, to illustrate which we have shown at fig. 3 in the engraving a side elevation of one of the cylinders now being sunk, and the necessary timber structure, and at fig. 4, a vertical section through the centre of fig. 3. The cylinders *a a* are 8ft. 4in. in diameter, cast in 6ft. lengths, and are kept in position by four guide piles *b b*. The outer piles are for carrying the platform, gantry, &c., in the usual manner. The main chain *c* is worked by

Digitized by Google

an engine placed as indicated in fig. 4, which is employed to raise or lower the apparatus. The excavator is attached to this main chain by two sets of chains A and B (fig. 1). The chains of set A, all of equal length, are each fixed to the outer frame of the excavator, and after uniting upon a ring are joined to the main chain a short distance above its junction with the other set of chains B by a length of single chain *d*. When the apparatus is descending, this length of chain is looped up by the monkey hook. There are eight chains to set B, all of equal length, and attached at their upper ends to the main chain in the way we have shown. These last chains are for the purpose of pulling in the spades up to the frame with the soil which they drag with them, and for raising the apparatus bodily to the staging above. When lowering the excavator, the connecting chain *d* of the outer set of chains A is looped up by means of the monkey hook, the chains of set B being thereby rendered quite slack—until the excavator reaches the bottom. The monkey hook is then thrown out of gear by means of the rope shown at *e*, which slackens the outer set of chains, and upon the hoisting being commenced, the inner set of chains is brought into tension, the spades drawn in, and the whole machine raised to the surface.

In order to ensure the excavator being both kept and forced down at the moment when the spades are being drawn into their places in the frame, a very effective arrangement, shown in fig. 4, is adopted. Two holding-down chains are fixed to opposite sides of the spade frame, and which pass under pulleys held down near the bottom of the excavation, and thence up to winding axles placed on the staging above. These winding axles are formed with enlarged drums, and also with handles for turning them by, and the holding-down chains are hauled up quickly by drawing ropes off the drums, on which they are re-wound by the operation of drawing up the excavator. The bottom pulleys for the holding-down chains are carried by timber spars or leaders, placed vertically, and which are held inside the cylinders. They are kept apart at their lower ends by a stout iron hoop, to the opposite sides of which the leaders are fixed, whilst their upper ends are made fast to the cylinder itself. As the excavation proceeds these leaders move downwards with the cylinders, being lengthened from above. The holding-down chains are hauled tight as the excavator descends, and when it has reached the ground surface, sufficient strain is put on them to force the spades into the earth, to keep the frame from rising whilst they are being drawn inwards, and to ensure their taking hold of the ground. As soon as the workmen feel that the spades are drawn close in, the holding-down chains are released and the excavator is raised up to be emptied. This is effected by running a lorry under the excavator and on which it rests; the outer set of chains A are then hooked up, and the excavator being raised a little, the spades fall open, and the soil is discharged into the lorry. Mr. Milroy's apparatus has been found to effect considerable economy in the Clyde Bridge works, from the simple and expeditious manner in which it performs its duties. Mr. J. F. Blair, the engineer of the works, has expressed to us his high appreciation of this excavator, and his thorough satisfaction with the results of its working.

MULES FOR SPINNING AND DOUBLING.

MR. B. DOBSON, of the firm of Messrs. Dobson and Barlow, of Bolton, and Mr. R. Halliwell, have just patented some improvements in spinning mules, which we make the subject of the accompanying illustration. The invention refers to mules when two speeds are required, and consists in making the horizontal rim pulley shaft in two parts, extending nearly the whole length of the headstock. The rim band pulley for the slow speed is on the end of one shaft, and that for the quick speed on the other shaft. The driving pulleys are placed at the junction of the above shafts, one pulley fixed to each shaft, and a loose pulley placed between the above pulleys. An endless band passes from one rim band pulley to the other over suitable guide pulleys to the pulleys inside of the mule carriage for the purpose of driving the spindles at the required speeds, and the band is tightened by making the guide pulley inside the carriage adjustable, this latter pulley being supported in a frame actuated by a screw. By this arrangement the speeds can be easily varied to suit the counts required by changing the rim band pulleys. The other portions of the mule are arranged to suit the above object, the twist or cam shaft being placed at right angles to the headstock, and the balance lever actuated by a tappet on the twist or cam shaft. The drawing rollers are driven by gearing from the horizontal rim pulley shaft at the back of the headstock. The carriage is drawn out by the differential motion which is driven from the shaft by which the drawing rollers are driven.

In our engraving (page 394), fig. 1 is an elevation, and fig. 2 a plan of the principal parts of a hand-mule constructed according to these improvements. *a* and *b* are the two parts of the horizontal or rim pulley shaft extending nearly the whole length of the headstock, the shafts *a* and *b* are supported in bearings, and their ends nearly touch each other in a line with the rims of the loose pulley a^1, and the quick speed pulley b^1. The pulley a^1 is loose on the shaft *a*, and the pulley b^1 is keyed on the shaft *b*; to the shaft *a* is keyed the slow speed pulley a^2. To the other extremity of the shaft *a* is fixed the slow speed rim band pulley *d*, and to the other end of the shaft *b* is fixed the quick speed rim band pulley *c*; both the rim pulleys *c* and *d* are capable of being taken off, and others of a different diameter put on in their stead; the endless band *e* passes from one rim band pulley to the other over suitable guide pulleys, and around the pulley *f* on the axle of the tin roller in the carriage *g*, as in mules of the ordinary construction. This endless band is tightened by means of the pulley *h*, which is mounted in an adjustable bracket *i* fitting on the frame J in the carriage, and the position of the bracket *i* is regulated by a screw and hand-wheel *k*, the screw passing through a nut fixed to the bracket *i*.

The other portions of the mule are constructed in the usual manner, but they are arranged to suit the peculiar disposition of the rim band pulley shafts, the twist or cam shaft *l* is placed at right angles to the headstock, the balance lever *m* is actuated by the tappet l^1 fixed on the shaft *l*; this tappet acts on a projection from the balance lever *m*, and lifts it up so as to relieve the rod to which the strap fork is fixed of the weight of the lever *m*; consequently, when the rod is unlatched in the ordinary manner, the strap which is now supposed to be on the pulley a^2 is moved from the pulley a^2 to the pulley b^1. As the twist shaft *l* continues to rotate, the tappet l^1 leaves the projection on the lever *m*, which is thus set at liberty, to act on the strap fork rod, and when the second tappet on the shaft *l* unlatches this rod, the weighted lever *m* moves the rod back, and brings the strap from the pulley b^1 to the loose pulley a_1, when the carriage has run into the roller beam, the strap rod is again unlatched in the usual manner, and the balance lever *m* changes the strap from the loose pulley a^1 to the fast pulley a^2.

The drawing rollers *n* are driven from the shaft *a* by the pinion a^3 gearing into a carrier wheel which drives the wheel n^2 fixed on the shaft n^1, at the other end of which is a bevel wheel gearing into another wheel on the usual coupling shaft of the front drawing roller *n*. The carriage is drawn out by the pinion n^3 on the coupling shaft of the front drawing roller *n* gearing into the carrier wheel *o* to which is fixed the change wheel o^1 gearing into another carrier o_2, driving the wheel o^3 fixed to the wheel *p* forming part of the differential motion. When the clutch box n^4 is disconnected, the train of wheels above described is at rest, and the carriage is taken out at a slow speed by means of the worm n^5 on the shaft n^1 gearing into a worm-wheel, on the boss of which is attached a change wheel gearing into the wheel *q* fixed to the bevel wheel p^2 forming the other side of the differential motion, the carrier bevel wheel p^2 then turns on its stud fixed to the socket p^3 fast on the usual drawing-out shaft *r*. The pulleys *s* s^1 and s^2, on the shaft *a*, are used for the purpose of assisting in backing off and winding on in the usual manner.

EXPORTS OF RAILWAY IRON.

THE year has opened well as regards the shipment of railway iron made to foreign countries and the colonies. The navigations to the north of Europe being closed, the returns of the exports made to Russia and Sweden are all but a blank for the first two months of this year, but very considerable deliveries were made to February 29, to the United States—viz., 32,942 tons, as compared with 20,321 tons in the corresponding period of 1867, and 6,995 tons in the corresponding period of 1866. British India also took 15,732 tons of our railway iron to February 29 this year, as compared with 11,494 tons to the corresponding date of 1867, and 10,395 tons to the corresponding date of 1866. The total exports of railway iron from the United Kingdom to February 29 this year were 74,853 tons, against 46,326 tons in 1867, and 53,358 tons in 1866 (corresponding periods). When the navigations of the north of Europe are reopened, Russian deliveries will no doubt largely swell this year's figures. It may be added that the value of the railway iron exported to February 29 this year was £585,817, as compared with £394,197 in the corresponding period of 1867, and £425,480 in the corresponding period of 1866.

THE DARDANELLES CANNON.

ONE of the giant cannons of the Dardanelles has, we understand, with a quantity of its shot, lately arrived at Woolwich Arsenal. This curiosity in the way of ordnance has been presented to our Government by that of Turkey, and will be placed in the museum of artillery in the repository grounds at Woolwich. The gun is of bronze, and in two parts; the hind part, or powder chamber, screwing into the fore part, or shot chamber. The screw in the hind piece is a curiosity in itself. It is 14in. long, and has five threads about 3in. wide and deep; the diameter of the screw is 24in. The hind piece itself very much resembles in form a windlass or capstan, having hand or lever holes all round at both ends for the purpose of screwing it to the front piece. The gun is without any trunnions, being intended to be laid on sleepers on the ground, as other similar guns are now placed in the batteries on the Dardanelles. It is evidently of great age, and similar to that described by Gibbon in his "Decline and Fall," as employed by Mahomet II. at the siege of Adrianople in 1453. The powder chamber in the breech part is 6½ft. long and 10in. in diameter. The bore, or shot chamber, is 25in. in diameter. The shot for this monster are round and of white granite; they weigh 650lb. each. The following are about the weight and dimensions of this interesting piece of artillery:—Breech part, 9 tons 18cwt.; length, 7ft.; front part, 8 tons 17cwt.; length, 10ft.

AMERICAN LOCOMOTIVES.

THE following annual statement of the performance of locomotives on the Illinois Central Railway for the year ending December 31, 1867, has just been issued in America by Mr. S. B. Hayes, the master of machinery on that line:—

1867.	Chicago branch.	South division.	North division.	Total.
Miles of Road	252·5	230·75	225	708·25
MILES RUN.				
By passenger trains	403,532	303,496	289,779	996,807
By freight trains	1,005,469	585,538	893,070	2,294,077
By other trains	251,007	149,372	85,313	484,332
Total miles run	1,660,008	1,038,406	1,066,802	3,765,216
RUNNING EXPENSES.				
Pounds of waste used	23,504	15,601	17,738	56,813
Gallons of oil used	13,139	9,906	8,333	31,379
Cords of wood used	20,891	1,516	1,096	4,701
Tons of coal used	48,714	28,026	29,042	105,782
Cost of wages	103,538	68,426	61,288	233,253
Cost of repairs	227,538	149,538	166,930	544,007
Cost of stores	...	...	...	...
Cost of fuel	123,160	73,187	72,318	268,665
Cost of cleaning engines ...	21,290	13,555	8,713	43,559
Total cost	486,074	312,692	316,735	1,116,102
COST PER MILE RUN.				
For oil, waste, and tallow, cts.	·67	·78	·72	·71
For repairs, cts.	13·70	14·43	15·63	14·45
For fuel, cts.	7·41	7·04	6·77	7·13
For wages, cts	6·23	6·55	5·74	6·18
For cleaning, cts.	1·28	1·30	...	1·15
Total, cts.	29·3	30·11	29·69	29·64
AVERAGE MILES RUN.				
To one cord of wood	...	...	...	...
To one ton of coal	33·24	36·23	36·75	34·98
To one pint of oil	14·84	13·10	15·09	14·76
Average number of cars p. train	14·07	13·84	10·65	12·35

The above oil includes that used in head-lights and in lamps of engineers; wood is rated a 7·00 dols. per cord, and coal at 2.50 dols. per ton, loaded on tenders; oil, 55 cents per gallon; waste, 15 cents per pound. Re-building, superintending, teaming, and all other expenditure relating to repairs, are included in the above cost of the performance of locomotives. Two empty cars are rated as one loaded. Whole number of engines owned by the company, 167. Average cost per mile, in cents, for—

Passenger engines	23.20
Freight „	32.28
Construction „	27.05
Switching „	21.18

AT the last fortnightly meeting of the Royal Horticultural Society, held at South Kensington, there were shown some new fancy pelargoniums from Mr. Turner, a collection of pyrethra from Mr. Salter, and a most interesting orchid Arachnanthe muscifera from Mr. Williams. A pelargonium was sent by the Rev. A. Rawson, on which Orobanche cærulea was parasitic. Another species of orobanche has been observed on pelargoniums by Mr. Halles. Mr. J. Russell Reeves, F.R.S., presided, and the following candidates were elected fellows of the society:—Mrs. F. Barrow, Mrs. J. L. Bell, Sidney Biddell, M.A., Mrs. Burne, Colonel Arthur Herbert, Dowager Countess of Lanesborough, Charles Meeking, jun., Miss E. A. Neal, M. le Chevalier de Rosaz (Advocate of the Court of Paris), Miss Williams, &c.

Digitized by Google

AMERICAN COAL.

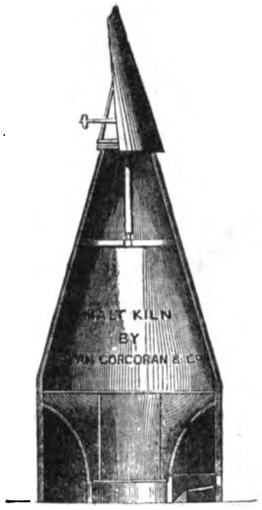
IT appears, from official American statistics, that the quantity of coal imported into the United States in the first four months of last year was 39,931 tons; in the second four months, 283,420 tons; and in the third four months, 145,371 tons, making a total import for 1867 of 468,722 tons. The value was returned at 1,334,261 dollars, or about £330,000. The quantity of English coal sent to the United States last year was 123,392 tons (as compared with 134,113 tons in 1866, and 197,401 tons in 1865). English coal thus figured in the foreign coal supplies of the United States to the extent of little more than one-fourth last year, the amount derived from other quarters besides England having been 345,330 tons. It is worthy of note that, although the population of the United States is now approaching that of France, the Americans import far less coal than the French. Thus, while 468,722 tons of coal were imported into the United States in 1867, the corresponding imports into France in the same year were 6,562,369 tons, although the French have made tolerably successful efforts during the last ten or fifteen years to utilize the coal wealth which they undoubtedly possess. After all, however, the coal resources of France are probably small as compared with those of the United States.

PRODUCING A VITRIFIED SURFACE ON CAST METAL.

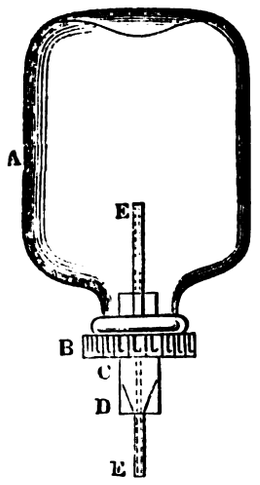
AN invention has recently been patented by Mr. E. T. Horsley, of Alfreston, and Mr. C. Horsley, of the Wharf-road, City-road, and which has for its object improvements in the production of a glazed or vitrified surface on cast metal. In producing castings of iron or other metal they coat the mould and core with powdered glass, furnace cinder, or enamel, or other material capable of being vitrified by the heat of the melted metal when it is poured into the mould, so as to form a glaze or enamel on the surface of the casting. The operation is as follows:—Prepare a mould in the usual manner either of common sand or red loam sand, and either with or without cores, as the case may require. When the mould is finished, paint it over with a paint-like composition prepared by grinding together gas tar and common blacklead in the proportion of about 2lb. of blacklead to a gallon of tar. Immediately dust over it finely ground window glass, or green bottle glass, or slag from a blast furnace may be used, as may also other vitreous materials or enamel compositions, such as are used for enamelling articles of wrought and cast iron, but when casting iron ground glass is preferred. Any excess of the powder is dusted or blown off, and the mould is allowed to dry, or is dried by artificial heat until the composition on its surface is set and hard, so that it will not rub off. The metal is then run into the mould in the usual way, the heat fuses the vitreous material with which the mould is lined, and causes it to form a glaze on the surface of the casting. The paint-like composition by which the powder was made to adhere to the mould also serves as a separation when the fusion takes place, and so a smooth face is ensured. This process is more especially applicable when casting iron, but it may also be applied advantageously in some cases when casting brass and copper, the vitreous material employed being such as fuses readily with the heat of the melted metal.

CIRCULAR MALT KILN.

OUR attention has recently been drawn to some improvements in the construction of malt kilns, which have been made by Messrs. Bryan, Corcoran, and Co., of 48, Mark-lane, and the New Sun Wharf, Ratcliff-cross, and about which we propose to say a few words. These kilns are circular in form, both in the lower portion and the dome, as will be seen by the accompanying engraving. This form conduces to the equal passage of the heated air through the floor, which is further promoted by the arrangement of the fire and the arches which enclose the kiln pit. Messrs. Corcoran have made malt kilns their speciality, and have arrived at great perfection in their construction, which is based on sound principles. Their kilns, capable of drying twenty-five quarters at a time, are 25ft. in diameter over the floor, and they have a 6ft. opening at the top of the dome. The kiln pit is 12ft. 6in. in diameter, and the floor is 12ft. 6in. above the grate level. The dome is 38ft., and the cowl 19ft. high. The floors in Messrs. Corcoran's kilns are of wove wire, and are strained through the walls by means of bolts and nuts screwed upon the outside. The wire plates are supported on round bars which are carried on wrought-iron beams, which are in their turn partly supported by wrought-iron girders, and are partly set into the walls. This arrangement makes an excellent floor, the round bars leaving nearly the whole surface of the floor exposed to the heated air, and available for work. We have referred to a kiln 25ft. in diameter, but this is not the longest made, Messrs. Corcoran having constructed one at Messrs. Day's brewery, at St. Neots, 30ft. in diameter.



Whilst looking round Messrs. Corcoran's premises in Mark-lane, where they have carried on business for nearly a century, we were struck with a very simple and efficient oiler for machinery. This is known as the needle lubricator, invented by M. Lieuvain, and is shown in the annexed sketch This apparatus is composed of a strong



globe of glass A, having a neck fitted with a stopper of wood B, through which is a conical metal tube C, forming the only exit for the oil. In order to regulate the supply of oil, a metal rod or needle E passes through the tube. The apparatus is filled with oil and turned neck downwards, and the lower end of the stopper is fitted over the bearing of the shaft. The needle E alone descends, and comes into contact with the parts requiring to be lubricated, the least movement of which produces an oscillation or vibration of the needle, which disengages a small portion of oil and causes it to descend from the globe, the quantity being in proportion to the speed. When the machinery stops, or is not in motion, no oscillation of the needle takes place, and the pressure of air at the base of the tube, also the partial vacuum formed in the globe, prevents the oil from descending until the machinery is again set in motion. Its economy in saving of oil is very great. We understand that an ordinary globe, containing but a small quantity, will lubricate a small shaft turning 150 to 200 revolutions per minute for upwards of a month. This lubricator has come extensively into use both at home and abroad, and it justly merits the success it has met with.

THE Royal Humane Society have awarded a medal to Mrs. Elizabeth Poingdestre, the wife of a Jersey clergyman, for rushing into the sea and saving a man from being drowned in February last.

THE MONCRIEFF ELEVATOR GUN-CARRIAGE.

IN our notice of the soiree of the Royal Society, we briefly alluded to Captain Moncrieff's system of working guns. Pending the preparation of some drawings which we were promised, we give the following description of this invention from the "Standard":—This gun-carriage, which is apparently one of the most important inventions in modern artillery, has been for some months in course of construction under the sanction of the Ordnance Select Committee, at the Arsenal at Woolwich, and in a few weeks will be experimented upon as adapted to a 7-ton gun at Shoeburyness. It has for a long time been a great desideratum for artillery of position to possess some means of firing over a solid parapet, while preserving free lateral range, without either exposing the gun or its detachment (*i.e.*, the artillerymen who serve it), or involving the labour of raising and lowering the piece at each discharge. This appears to have been now fully obtained by Captain Moncrieff's invention, with the immense advantage of almost completely neutralizing the destructive effect of the recoil upon the gun-carriage, platform, and pivot; and, moreover, utilizing the force of the recoil for the working of the gun itself. The gun carriage, which is of a peculiar form, is mounted upon a quadrant-shaped piece, called the "elevators," to the top of which it is pivoted; the curved part of the elevator rolls like a wheel upon the traversing platform upon which it is mounted, and a counter weight is attached in front a little in excess of the weight of the gun. This counter weight absorbs the force of the recoil; consequently, when the gun is discharged the elevators roll back upon the platform, causing the gun to descend in a cycloidal curve, the leverage in favour of the counter weight going on in an increasing proportion as the gun sinks, so as to be able to meet the utmost force of the recoil; the gun thus sinks some 4ft. below the crest of the parapet. The gunners are then enabled to reload in perfect security; and when the gun is to be again fired a self-acting pawl, by which it is kept in the loading position, is released, and it immediately rises to its firing position over the parapet. The advantages of these conditions for a heavy piece of ordnance in battering in an earthwork must be patent to any one at all acquainted with practical artillery. They chiefly consist in—

1. Protection from direct fire.
2. Unlimited lateral range.
3. Economy in construction of works.
4. No mark is offered to the enemy to fire at, as the gun is masked till the moment of firing, being entirely concealed behind the parapet.

With regard to the first-mentioned advantage, as the parapet may be of any thickness of earth and there are no embrasures, there is no necessity for any greater protection to the gun detachments than that given by the parapet itself, behind which they remain completely under cover.

Second.—Lateral range.—The lateral range is the same as that of guns in a cupola, and will entirely alter and modify the trace of future fortifications, whether field or permanent, in which this system is used, as guns in a face will have the same power as guns in a flank. Moreover, a most excellent mode of mounting these guns has become for the first time possible, viz., that of putting them in pits of, say, 18ft. diameter and 10ft. in depth; thus no fortification would be visible to an enemy.

Third.—Economy in the construction of works.—The improved accuracy and increase of penetration of modern ordnance have only been met hitherto by the employment of iron in fortifications, which, however, from its enormous expense and other disadvantages, was only thought of because no other alternative appeared to present itself. A two 12-ton gun cupola in itself costs about £15,000, and what Gibraltar shields and other plans for iron defences will come to, if adopted, Heaven only knows. The employment of Captain Moncrieff's protected barbette system ought, in almost every circumstance, to obviate any necessity for the use of these extravagently-costly methods of protecting modern fortifications, which even may themselves be found insufficient to cope with a further improved artillery; whereas with this system, if the parapet is simply thickened, which it can be *ad infinitum*, it will set increased penetration at defiance, and it is to be hoped that if this system be finally adopted the country will bear in mind the immense saving to its finances from the labours of the inventor, who, for a long period of years, and at a great expense, has at last succeeded in developing the practical utility of his system.

Fourth.—Economy of life.—None of the conditions produced by the greatly-increased range and accuracy of small arms, or the enormous concussion of the monster cannon shot of the present day, can affect the gunners in the present case, occupying as they do the defiladed space in rear of a high parapet, and completely under cover, for the elevation of the parapet would be about 10ft. from the ground to the interior crest.

Sixthly.—Making the gun.—As the gun is only visible at the moment it is raised above the parapet to be discharged, and as even for that moment it may be masked by a brushwood screen, it is evid e

Digitized by Google

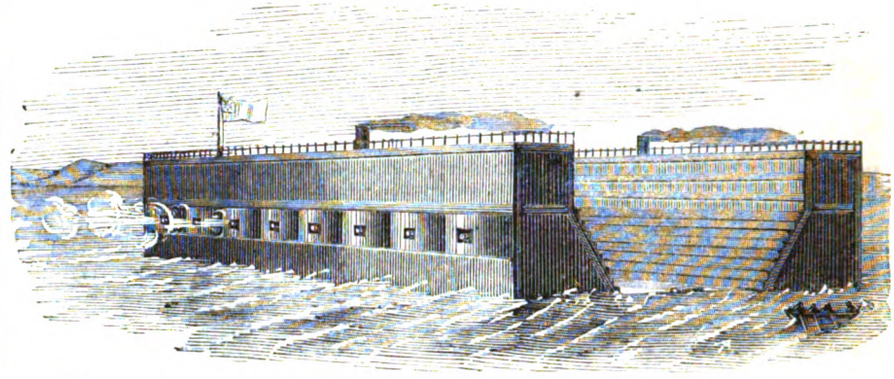
hat it is masked till fired, and immediately it is fired it drops again behind the parapet, so the eye of the enemy has nothing to guide it but a whiff of white smoke rapidly changing its position and drifting to leeward. One can imagine nothing more distressing to a hostile ship than to receive a galling fire from every green hill in the vicinity of a fort which she was about to attack without possessing any means of exactly determining the position of her tormentors.

To conclude this notice, it were well if attention were drawn to the enormous expense attending the proposed great employment of iron in our fortifications, and to pause before spending the millions necessary for the proposed works; for may they not be advantageously economized by the adoption of the foregoing invention for the armaments of permanent fortifications? and in cases where new fortifications are to be constructed, they may be adequately replaced by long lines of earthen parapets only elevated about a foot above the glacis, behind which the armament would remain, the more formidable because unseen. A further improvement may be made with this class of work, hitherto uncontemplated on account of the mechanical difficulties in the way, for a line of rails may be laid down parallel to the crest line of the parapet, upon which the platforms on which the guns are mounted can travel on trucks; therefore, if the lines be long, you can concentrate your artillery immediately upon any point at which it may be most required, the guns admitting of being discharged upon the trucks on which they are mounted, as there being a moving fulcrum between the gun and the platform, the rails would not be torn up by the transverse strain, which would infallibly be the case with rails laid in the ordinary manner were the gun mounted on the usual service carriage, for they would then have to bear the force of the recoil; the whole weight of the gun and platform would be considerably under that of a heavy locomotive, which weighs about sixty tons. The guns could, therefore, even be pushed by their detachments from point to point without being exposed to view. As it is the action of the counter-weight which raises the gun from its position under cover to the firing position over the parapet, for naval purposes the action of hydraulic power, steam, or compressed air may be substituted for it in cases where it would take up too much space. In fact, the number of conditions to which this novel and extremely simple mechanical principle may be adapted would require much more space than we have at our command to describe or particularize.

DOCKING AN IRONCLAD.

OUR readers are doubtless aware of the existence of an extensive dockyard and a floating dock at Cartagena. On the 26th of last month, an event occurred in connection with it of considerable interest, namely, an armour-clad ship, larger and heavier than the English Government ship "Bellerophon," was raised by means of the floating dock for the purpose of repairs. As a floating dock is now building in England for that class of ship, it may be interesting to know that such a ship has actually been lifted. According to the "Times," the well-known "Numancia," ironclad ship, having returned from the Pacific, was required to be docked for the purpose of making good the damage done during her attack on the forts of Callao, the most notable injury being due to the effect produced apparently by a 9-inch or 10-inch projectile, which had struck the ship just between wind and water, and crushed the armour-plating into the wood backing without actually penetrating the inner skin, but had made such an indentation that it was absolutely necessary to dock the ship. As there is no graving dock in the Spanish peninsula of sufficient dimensions to take in a vessel of the "Numancia's" class, it was determined to employ the iron floating dock of Cartagena for that purpose. There were many grave doubts as to the dock being able to lift the ship. However, orders were received from the Ministeria de la Marina at Madrid to dock the "Numancia" without delay. This order found the dock in its shallow basin (in which it was originally built), undergoing a process of cleaning and painting, which had not been done since the dock was first used, some three years ago; but before this was completed the dock was hauled out and moored in the deep-water basin, ready to receive the "Numancia." At 11 a.m. on the 25th the "Numancia" was placed over the keel and bilge blocks, and the engines and pumps of the dock set to work very slowly. Soon the dock was observed gradually to rise, and the "Numancia" with it. However, twenty minutes had hardly elapsed when orders were given to stop, to adjust the shores for supporting the ship sideways, and so it went on stopping and moving until six in the evening, when the ship was nearly half lifted out of the water, and in that state she remained until half-past seven next morning. The pumps were again set to work and continued working with little interruption until noon. By that time the floor of the dock with the ship was above the level of the water. The weight of the ship, although lightened of its stores, was over 5,600 tons, and as no vessel had hitherto been lifted of that weight in Spain or elsewhere, it was considered desirable by the engineer in charge to use the utmost care and caution in raising it as slowly as possible, that the weight might be properly adjusted, for which purpose the pumps were only driven at one-third of their usual speed. During the process of lifting no canting or irregular motion was in any degree observable, but the whole operation was done with a regularity that produced confidence as to its safety. The dock had been sunk 40ft. in order to insure the vessel being easily hauled in; the time of actual lifting was 8hrs. 13min. It might be performed under 4hrs. on another occasion, but when the great weight of the vessel is taken into consideration, it is certainly a remarkable feat to have accomplished. The "Numancia" is built entirely of iron, with the exception of the teak backing for the armour plating; she is 316ft. long, 57ft. beam, draught of water 27ft. 4in., with a displacement of 7,420 tons (her displacement on leaving for the Pacific was 8,200 tons); she is completely encased by 5-inch armour of 1,500 tons weight, and pierced for forty 68-pounders. The port cills, with provisions for 600 men, and 1,000 tons of coal on board, are 7ft. 6in. out of water; her full speed thirteen knots; her engines are 1,000-horse power, developing nearly 4,000. The Cartagena dock was designed and constructed by the Rennies, civil engineers, and was the first introduction of iron floating docks; the length is 324ft.; breadth outside, 105ft.; and inside, 78ft. Two days after the "Numancia" was on the dock a thorough examination was made by the Spanish Engineer-in-Chief, Don Thomas Thalierie, when there were no perceptible alteration found in any of the internal bulkheads or bracing, and all seemed as true as when originally made. This speaks well for English workmanship, material, and the good principles on which the work was designed.

COMBINED FLOATING DOCK AND BATTERY.



Correspondence.

COMBINED FLOATING DOCK AND BATTERY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—As your readers are quite familiar with iron floating docks, constructed so as to lift for repairs vessels of the heaviest class, I will merely explain the idea embodied in the enclosed sketch. The middle compartment of such a structure is merely to unite the basement with the top chamber, the water simply flowing into the middle chamber, and flowing out again; no pumping, as erroneously supposed, is required to fill or empty this chamber—so I have utilized this space, by forming it into a powerful battery, the great base on platform of the dock enabling me to place therein guns of the heaviest calibre.

The dock has a semicircular front, and at the back a caisson is fitted, so as to insure great stability for docking ironclads, the form of the battery resembling an elongated horse-shoe, with indented embrasures, so as to be able to fire right ahead, when the dock is securely moored. The design being simply to protect our harbours and mouths of rivers, and as the guns would be heavier than what can possibly be carried on board ship, I would merely armour-plate the top and sides of mid-chamber, and the top of basement, to protect it from vertical fire, depending on the heavy guns to keep without reach of the enemy's shot. When the dock is used for docking purposes, the ports would be filled up with suitable water-tight doors.—I am, Sir, yours, &c.,

JOHN G. WINTON.

13, Gladstone-street, May 15.

A BRONZE Roman coin of the age of Phillipus the Younger, A.D. 249, has been dug up at Carisbrook, in the Isle of Wight.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Meetings for the Week.

MON.—Royal United Service Institution.—Mr. John Elder on "Circular Ships of War with Immersed Motive Power," at 8.30 p.m.

TUES.—The Institution of Civil Engineers.—The President's Annual Conversazione, at 9 p.m.

Royal Institution.—Dr. M. Foster on "The Development of Animals," at 3 p.m.

THURS. — Royal Institution. — Professor Grant on "Astronomy," at 3 p.m.

FRI.—Royal Institution.—Mr. W. E. H. Lecky, on "The Influence of the Imagination upon History," at 8 p.m.

SAT.—Royal Institution.—Professor Grant on "Astronomy," at 3 p.m.

Naval, Military, and Gunnery Items.

DURING the past week thirty-nine wrecks have been reported, making for the present year a total of 894.

THE annual regimental dinner of the brigade of Grenadier Guards takes place on June 2, at Willis's Rooms.

STATISTICS have lately been compiled on the subject of deaths at sea by the Registrar-General of Seamen and Shipping, which form a continuation of a return moved for in the House of Commons by Mr. Graves last year. These statistics show that, during the year 1867, 5,283 deaths are recorded as having occurred among the crews of British ships at sea, 2,370 of which were due to disease, 1,808 were caused by wrecks, and 1,105 by accidental drowning. The deaths from diseases of all kinds are less than those of the previous year, but the total number caused by wrecks indicates a considerable increase.

IT is in contemplation to discontinue the issue to the troops of fuel in kind, and to substitute a money allowance to each corps. The "United Service Gazette" says that an officer is to be appointed in each regiment as treasurer, under the supervision of the commanding officer, of the funds thus allowed, whose duty it will be to make contracts for the supply of fuel, and also to superintend the canteen stores. Additional pay will be granted to the officers filling this office. Many advantages are expected from the new system, particularly, we opine, to the chief regimental authorities.

IN the Court of Admiralty, the other day, before the Right Hon. Sir R. Phillimore, the case of the claim made by 350 seamen against the "Great Eastern" was heard on appeal. Objections were taken by the Great Ship Company to the finding of the Registrar as to the claim of about 350 sailors who were dismissed last May, when the vessel arrived at Liverpool, after the failure of the speculation on account of the French Exhibition. Mr.

Digitized by Google

C. P. Butt appeared for the ship, and the Solicitor-General, Mr. V. Lushington, Mr. R. G. Williams, and Mr. James Aspinall for the men. After a long legal argument, his lordship reserved judgment.

THE National Lifeboat Institution has presented to Mr. Quigley, of the Coastguard, Whitby, its silver medal and an inscribed record on vellum for having during winter descended by a rope the cliffs south of the harbour, 300ft. in height, and thus saving the lives of four persons, being the master and crew of a schooner wrecked on the rocks, out of reach of lifeboat and rocket apparatus. The master had a broken leg, but was safely landed. Nine other men who aided in the exploit are suitably rewarded. The vessel went to pieces, and but for the prompt action of the men referred to all must have perished.

THE "West Cork Eagle" records the following extraordinary passage in an open boat:—On the 7th instant, Mr. William Salter, with only one man, sailed from Cowes, Isle of Wight, for Baltimore harbour in a small open pleasure boat, purchased there by Sir H. W. Beecher, Bart. Great uneasiness and anxiety were felt by the friends of these daring men, who ventured such a distant and dangerous passage in so small a craft; but we are glad to learn that their friends were relieved of their anxiety by getting a letter on Friday from Mr. Salter, stating that he put into Youghal through stress of weather, and praising the seaworthiness of his little boat. It appears that they went through very heavy weather and high seas.

THE trial trip of the "Victoria," iron-cased frigate, built by the Thames Ironworks Company for the Spanish Government, engined by Messrs. John Penn and Son, has just been made at the Maplin measured mile. The dimensions of the ship are:—Length, 316ft.; breadth, 57ft.; depth, 38ft.; burden, 4,862 tons. She is completely armour-plated from stem to stern with 5½in. plates and 10in. teak; the engines, of 1,000-horse power, nominal, are of the same type as those of the "Warrior" and "Minotaur." The frigate left Gravesend at 11·30 a.m., arriving at the Maplin at 1 p.m., where the trial at once commenced. The mean of the four runs was 14·1 knots; revolutions of engines, 65; pressure of steam, 23lb. The engines worked in a most satisfactory manner, indicating 4,500-horse power. The weather was all that could be wished, but the tide being half ebb was unfavourable to the trial.

Miscellanea.

A TORNADO visited Shanghae, Illinois, on Sunday, the 3rd inst.; fourteen houses were blown down, several others unroofed, four persons were killed, and forty injured.

A BRONZE statue of Sir Peter Fairbairn, who, as Mayor of Leeds, was knighted by the Queen when her Majesty opened the Town Hall in 1858, was inaugurated in Leeds yesterday week.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending May 16, was 2,435; total number since the opening of the museum, free daily (May 12, 1858), 1,298,147.

MR JOHN CRAWFURD, the distinguished Oriental scholar and ethnologist, died on Monday week at his residence, in Elvaston-place, South Kensington. He was born on August 13, 1783, in the Island of Islay.

THE Council of King's College, London, have elected the Rev. Dr. Barry, head master of Cheltenham College, to the office of Principal. Dr. Barry was fourth Wrangler, and second Smith's Prizeman, seventh on the first-class of the Classical Tripos, and formerly Fellow of Trinity College, Cambridge.

THE number of visitors to the South Kensington Museum during the week ending May 16, 1868, was —On Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 8,322; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,720. National Portrait Exhibition, by payment, 2,661; Total—12,703. Average of corresponding week in former years, 10,952; total from the opening of the Museum, 7,386,183.

THE contract for the Calcutta Waterworks is being proceeded with. The concrete is laid over a considerable portion of the area of the tank in Wellington-square. We regret to learn that the contractor's engineer has been obliged to leave for England, owing to bad health. Another engineer, Mr. Aird, has, however, arrived, and is pushing on the works as rapidly as possible.

THE broccoli season for West Cornwall is over, and shows a great improvement on last year. The West Cornwall Railway has sent off 3,600 tons, against 1,500 in 1867, and 3,200 in 1866. These have come principally to London, but they have been sent to many other large cities of England also, and as far north as Hull and Edinburgh. In addition, the neighbourhood of Penzance has furnished West Cornwall with a constant supply of broccoli from December to April.

THE publication of the "National Records of England and of Scotland" will probably be completed in the course of the present year. It is proposed then to publish the facsimiles of "National Records of Ireland." There is a steady demand for the facsimile of "Domesday Book"; the sum of £3,556 has been expended in the publication, and at the end of February £1,938 had been received from the sale of copies, and the copies in store would produce £1,900, so that the sale will more than cover the cost of publication.

FRANCE has imported wheat very heavily this year. In the two months ending February 29 she received wheat to the value of £36,498 from the United Kingdom, £33,069 from Belgium, £375,819 from Russia, £252,610 from the Zollvercin, £115,577 from Italy, and £721,333 from Turkey and the Principalities, making a total of £1,534,906. In the corresponding two months of 1867 the value of the wheat imported into France was only £509,203; and in the corresponding two months of 1866 only £4,203.

DURING the first two months of the current year Belgium received from the United Kingdom 883,986 kilogrammes of soda, and chemical products of other kinds, amounting in value to 213,344f.; 21,442 tons of coal, 316,232 kilogrammes of coffee, 21,045 kilogrammes of flour, bran, &c., 3,310,672 of raw cotton, 52,150 of earthenware, 42,670 of herrings, and 48,157 of other kinds of fish. The other articles largely imported from England to Belgium are metal wares, rags, salt, textile manufactures, and raw wool.

BY a return issued on Wednesday week, it appears the sum required in the year ending March 31, 1869, to enable the Lords Commissioners of Her Majesty's Treasury to make the necessary advances for the purchase of a site, and for other expenses for the new courts of justice and offices belonging thereto (the amount of such advances to be repaid to the Consolidated Fund out of the surplus interest fund of the Court of Chancery), is £106,000. Of this sum £86,190 13s. 1d. is a re-vote.

THE American correspondent of the "Times" states that the present Congress is known as preeminently a Congress of jobs. There are now pending, in various stages of unfinished legislation, bills appropriating no less than 268,250,000 dollars, to various railways and navigation companies, the profit of which is intended to go into private pockets; and besides these there are also pending bills making all manner of land and money grants for every conceivable object. Every man who visits Washington seems to consider that he has a *carte blanche* to rob the Treasury.

A CHANGE of some importance has been made in the time at which the lectures at Gresham College are, for the future, to be delivered. Hitherto the lecturer has taken his place at one o'clock in the afternoon, but, from a prospectus which has just been issued, it appears that the lectures for Trinity and Easter terms will be delivered in the evening. Dr. E. Symes Thompson is the lecturer, and, on Monday evening next, at seven o'clock, he will deliver the first of the Trinity term series. His subject will be "On the Causes of Disease."

A NEW line of railway, unimportant in a commercial aspect, but which will be welcome to the tourist and the sportsman, has just been opened. The line is that of the Tees Valley, about nine or ten miles in length, which joins the Stockton and Darlington Railway, near Barnard Castle, and goes to within a short distance of the celebrated High Force, a magnificent waterfall. The scenery in the neighbourhood is some of the most picturesque in England; while the long stretches of moorland, on which grouse abound, which extend into Westmoreland, will afford ample pastime for the sportsman.

THE East Indian Irrigation Company publishes the following:—The accounts from Orissa are very satisfactory, both as to the spread of irrigation and the construction of the works. Upon the Midnapore Canal one zemindar was about, at his own expense, to construct a channel to carry water to his lands, upon which he had engaged to employ 500 labourers. This same zemindar had also signed a lease for 1,000 acres on another portion of his property, and had promised to execute another for 3,000 acres. Navigation had also commenced upon the opened portion of the Kendrapara Canal, although none was expected until its completion to tidal water,

A MINERAL discovery, which promises to be important, has recently been made on the banks of the River Don, Tasmania. A lode has been found, yielding cobalt, silver, copper, and antimony. A few stones broken from the lode were, a short time since, forwarded to an assayer at the Wallaroo Smelting Works, for analysis. The result was as follows:—Cobalt, 4oz. in the ton; silver, 100oz.; copper, 14 per cent., and a quantity of antimony. The ore is estimated at worth £85 per ton. A specimen of lead, as taken from the same locality, has also been analyzed, and found to contain 82 per cent. of pure galena, besides several ounces of silver to the ton.

A REMARKABLE plant is now in flower at the Royal Botanic Gardens of the same genus as the American aloe. The popular belief in England is that it is the nature of these plants to bloom but once in a century, but the fact seems to be that this peculiarity is attributable to them only in a cold climate like our own, and that in their native Mexico they reach the period of bloom in about fifteen years. Having flowered, they rapidly pine away. The flower now on view is called the Fourcroya longæba, and was raised from seed received from Mexico about twenty-eight years ago. In its native country it produces flower spikes more than 40ft. long. The flower is expected to remain some time in bloom.

DURING last week the mail and express trains between York and Scarborough were fitted with the new cord arrangement invented by Mr. George Brown, of the North-Eastern Railway. A trial train was sent down the line, and the experiments with that, and with the passenger trains since, have been very satisfactory. The arrangement is very simple. A cord passes above the door within reach. A pull forward sounds the whistle, and a pull backward rings the guard's bell; but the cord cannot be used without first springing a semaphore signal indicator from the side of the train at the part where it is in request. This signal locks itself, and cannot be put back except by the guard. The company intend to fit the arrangement to their summer expresses to Scarborough.

THE condition of the milk supplied to the inhabitants of London has been investigated by the "British Medical Journal," and a second report upon it appears this week. According to the date furnished by a series of chemical analyses by Dr. Divers, F.C.S., it seems that out of sixteen samples of milk, purchased in the Bayswater, Kensington, and Holborn districts, only one proved to be in its original state, all the others being more or less watered and deprived of cream. One specimen, for example, proved to be nearly half water; another to have lost more than half its cream, besides being diluted with water. A charge of fivepence per quart for two of the samples was found to be no guarantee to customers willing to pay the extra penny that they can assure to themselves, by so doing, a supply of pure milk.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3094, 3122, 3123, 3131, 3133, 3138, 3139, 3142, 3168, 3169

BUILDINGS AND BUILDING MATERIALS—3121, 3141

CHEMISTRY AND PHOTOGRAPHY—3132

CULTIVATION OF THE SOIL, including agricultural implements and machines—None.

ELECTRICAL APPARATUS—None

FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3091, 3092, 3093, 3098, 3099, 3100, 3101, 3103, 3113, 3114, 3134, 3135, 3136, 3152, 3153

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—3120, 3140

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—3104, 3137, 3149, 3162, 3165

GENERAL MACHINERY—3106, 3109, 3110, 3116, 3124, 3126, 3147, 3148, 3156, 3159, 3163, 3164

LIGHTING, HEATING, AND VENTILATING—3105

METALS, including apparatus for their manufacture—3107, 3157

MISCELLANEOUS—3096, 3097, 3102, 3108, 3111, 3115, 3117, 3118, 3119, 3125, 3129, 3130, 3146, 3150, 3154, 3158, 3166, 3167, 3170

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—3128, 3143, 3144, 3151, 3161

SHIPS AND BOATS, including their fittings—3095, 3112, 3145

STEAM ENGINES—None.

WARFARE—3127

3091 T. B. CUTTS and F. W. BROOKSBANK. *Improvements in the manufacture of laces in twist lace machines.* Dated November 2, 1867.

According to this invention the patentees produce the desired twisting of the bobbin wefting threads at the edges of the weavings by lapping the warp threads which form the longitudinal threads of the weaving around the bobbin wefting threads, not only so as to lay the said bobbin threads over and under them alternately, in the usual manner, but also so that the said longitudinal warp threads of the weaving, as they straighten in the work, drag one of the wefting bobbin threads around another, and so produce the twist required.—Patent completed.

3092 W. COOKE and W. FRANCIS. *Improvements in mats and matting.* Dated November 2, 1867.

This invention relates to the manufacture of mats and matting for cleansing the feet, covering floors, packing or wrapping, and other purposes, and consists chiefly in the adaptation to such manufactures of the interior portions of common cane, such portions being usually wasted or destroyed after their separations from the exterior portions of the cane which are employed in the manufacture of chairs, and for other like purposes. In carrying the invention into practice, this refuse portion is divided or separated into fibres of suitable thickness and flexibility,

Digitized by Google

and is then ready for use. In the manufacture of mats for cleansing the feet and similar articles, the cane fibre may be interwoven with strands or cords of hemp, cocoa-nut, or other fibre, and afterwards cut or divided to form the desired brush-like surface.—Patent completed.

3093 J. ORR. *Improvements in doubling, folding, or plaiting woven or other web fabrics, and in the machinery or apparatus employed therein or connected therewith.* Dated November 4, 1867.

This invention consists in giving an intermittent forward traverse to the cloth or other textile fabric in the direction the plaits or folds are doubled over each other, or from the part where they are folded upon or over the surface of a roller, straight plate, or table surface below or between it, and a thin or fine-edged folding knife, blade, or bar, or made to reciprocate in sequential order or equal time with the said intermittent forward traverse, and in the same direction right across the length of the plaits or width of the fabric to be folded; that is, at the time each forward feeding motion of the fabric stops, the edge of the folding knife is brought forward in the same direction to the extent of its backward traverse, so as to bring forward a corresponding length of the fabric over the surface of the roller or plate below the knife, and double up and fold the part in front of the knife over itself in the form of a loop or bow of two thicknesses, and crease and wedge the part of the lower thickness of the doubled cloth above the knife and the thickness carried forward below the knife, and held by its edge between the lower feeding roller or table surface and an upper feeding and pressing roller, or other equivalent surface, which then catches hold of it and carries the three thicknesses or double folded part forward, at the time the folding knife is making its backward traverse for a fresh length of fabric to be clipped or caught, taken up and folded in like manner.—Patent completed.

3094 C. RILEY. *Improvements in tubular boilers.* Dated November 4, 1867.

The patentee claims the placing or fixing of a perforated plate, grate bars, or other form of fire protector, between the burning fuel and the heating surfaces of the boilers. —Patent completed.

3095 W. DAY. *Improvements in the mode of applying metal sheathing to composite ships with iron fastenings.* Dated November 4, 1867.

The patentee claims the application to composite ships with iron fastenings of a sheathing of zinc, or other electro-positive metal, in such a manner as to bring the said metal sheathing in contact with the heads of the iron bolts or other iron fastenings; and also the application of zinc washers to the inner ends of the iron bolts or fastenings, for the purpose of establishing a galvanic connection of the ironwork inside the vessel with the zinc sheathing, so that, when immersed in water, or partly so, the galvanic action of the two metals may prevent the corrosion of the iron bolts or fastenings, and the fouling of the sheathing. —Patent completed.

3096 J. FRASER and G. DUNCAN. *Improvements in counter-check books.* Dated November 4, 1867.

The object of this invention is to provide the said check books in such a form that the labour of checking the receipts will be greatly reduced and much time saved. For this purpose the inventors print the invoice heading on the faces of the seller's checks in the usual manner, but instead of printing the distinguishing numbers or characters on the faces of the slips, they print them on the back thereof, on all the three portions, on a part not likely to be written over. By so doing the distinguishing numbers or characters appear one on the back of the buyer's check, which is of no importance, and the other two, from the mode of use above explained, on the same sides of the counterfoil and seller's check, on which the writing and figures appear. The corresponding distinguishing numbers or characters are printed at one operation, slip after slip, by consecutive numbering, or any ordinary printing machine or press. In practice they usually print on large sheets, both before and after they have been perforated, and cut out the slips, which are afterwards bound up into books of the required size.—Patent abandoned.

3097 W. DICKINSON. *Improved means of joining leather or other material in the constructing or repairing of straps or driving belts for machinery.* Dated November 4, 1867.

The patentee claims the application and use of nails or headed and pointed pins of wrought iron, or other suitable metal, and washers or "burrs" to form or constitute revils in the construction or repair of mill straps or driving belts for machinery.—Patent completed.

3098 R. ACKROYD and G. HODGSON. *Improvements in looms for weaving.* Dated November 4, 1867.

This invention relates to means of operating the healds or heddles in looms for weaving, and the improvements consist in the employment of a set of jack rods and levers under the healds or heddles in addition to the ordinary set above them.—Patent completed.

3099 J. CLARKE and T. HOLT. *Improvements in warping.* Dated November 4, 1867.

Warping mills have formerly been constructed to lay the yarn upon the swift in layers of spiral form, and for convenience in taking it off space has been left between the spirals, as it has been found that, when not kept apart, there has been a tendency in the spirals to become entangled. The invention consists in placing upon a carriage, movable on a pillar or post, a roller, so as while the yarn is freely drawn over it, the carriage in which it moves shall have a movement perpendicular to the surface movement of the swift, and corresponding to the rate of delivery of the spirals thereon. To prevent the yarn from spreading over the ends of the before-mentioned roller they place other two rollers on studs, one at or near each end of the same, between which guiding rollers the yarn passes. They obtain the motion suitable to traverse the roller carriage from the well-known motion by which the jack is caused to travel on its post, but as this motion may be independently obtained from the motion of the swift, they do not confine themselves thereto. Motion is proximately conveyed to the roller carriage by means of an endless chain or band; but this also may be varied, and they do not confine themselves thereto, the invention being—the traversing upon its post or pillar a suitable carriage, having a roller furnished with upright guiding rollers by means of a motion corresponding more or less exactly to the motion which is imparted to the jack in laying the yarn spirally upon the swift, by which the yarn may be kept disentangled when being taken off.—Patent abandoned.

3100 R. BAGULEY. *Improvements in the manufacture of shuttles employed in weaving.* Dated November 4, 1867.

This invention has for it object the construction of "shuttle pegs" or skewers with the desired expansion and elasticity for securely holding the cop thereon without the aid of springs or other contrivances, as heretofore used for that purpose. This the inventor effects by securing the bent or arched portion of the said peg or skewer at the nose end thereof, and tempering or hardening the same whilst in an arched position, thus securing the elasticity required; the loose end of the arched portion of the said peg or skewer is pointed and received in a hole or groove formed for that purpose at the block end of the peg or skewer.—Patent abandoned.

3101 H. HEBDEN. *Certain improvements in mules for spinning, doubling, or twining cotton or other fibrous substances.* Dated November 4, 1867.

The patentee claims, first, the use of two shafts, one parallel to the other, so as to drive one from the other during the "single speed," and by altering the position of the intermediate gearing, and which alteration shall effect simultaneously an immediate change of the "speed" of the spindles, as required, in the manner and for the purpose described. Second, the arrangement and combination of mechanism whereby the change of pinion and intermediate gearing shall simultaneously alter the speed of the entire mule during the formation of yarn or first part of draw, called the single speed; and, third, the use, when required, of a change pinion and intermediate gearing for the "hardening" portion of the draw, called the "double speed," as described.—Patent completed.

3102 A. A. L. HARRISON. *The making of the improved label band.* Dated November 4, 1867.

This improved label band for holding papers together is formed by combining two parallel plates or strips of tin or other metal with one or two (according to the purposes and strength for which the bands may be required) india-rubber bands passing through removable wire links fixed at both ends of each of the two tin plates into tubes made by turning inwards the long edges of the tin plates. These wire links are somewhat in the shape of a horse-shoe; they would be slightly bent towards the curved end, and these curved ends would be enveloped with brass, metal, or tin movable tubing, and if one india-rubber band only be required, it would be inserted through the links, and would run through the grooves formed by the tubes. But if two india-rubber bands are required, they would not pass through the grooves, but each would pass through the two opposite wires of the tin plates. The tin plates would be japanned, and the outside surface of the upper plate would hold an adhesive paper gum label. Where one india-rubber band only is used, the construction of the plates would be as follows:—The tubes would not be carried throughout the whole length, but the space of an inch, or thereabouts, would be interposed in the middle of each of the two tin plates, and that space of tin would be folded on either side the depth of the tube, and parallel with the parent plate, but leaving a small interstice for the insertion of the india-rubber, which this part of the plate would shield from the rubbing of any papers held by the improved label band.—Patent abandoned.

3103 T. WRIGHT and I. FOX. *Improvements in machinery or apparatus for producing plain and fancy wearings in bobbin net or twist lace machines.* Dated November 4, 1867.

Heretofore, in producing plain or fancy weavings in bobbin net or twist lace machines, the weft threads have been traversed to the right or left across two or more breadths of work in the machine, other threads at each side being at the same time traversed in like manner. Now, by this invention, the patentees throw or traverse one thread quite across the machine from side to side, either way, such thread forming the weft in the whole width of work in the machine. This thread they cause to traverse by the employment of special machinery or apparatus, the details of which we cannot give space to here.—Patent completed.

3104 N. BIRKENRUTH. *Improvements in mattresses, cushions, sofas, seats, and other similar articles.* (A communication.) Dated November 4, 1867.

Heretofore, in the construction of mattresses, cushions, sofas, seats, and other articles for sitting, reclining, or resting upon, where an elastic or resilient or spring surface is required, it has been usual to form such surface by interposing between two plane or horizontal surfaces of textile fabric, or other like material, a number of springs, or a resilient substance or yielding agent generally, disposed vertically, so that a certain springiness has been obtained. Whereas, according to this invention, the horizontal surface is formed of a number of slender, pliant, or flexible wires interlaced, intertwined, or woven together, or traversing or passing under and over each other, and attached at the ends and sides to a rigid frame. The wires are so interlaced as to leave sufficiently large interstitial openings to ensure the requisite resilience. It is preferable to have two parallel layers or surfaces of wire formed as described, one over the other, and very near to it.—Patent abandoned.

3105 J. KIDD. *Improvements in obtaining artificial light and in the apparatus employed therein.* Dated November 4, 1867.

This invention consists in producing a mixture of atmospheric air, or air and coal gas combined with the heated vapour of non-volatile heavy hydrocarbons, and in burning such mixture for the purpose of obtaining light therefrom.—Patent abandoned.

3106 A. V. NEWTON. *Improvements in sewing machines.* (A communication.) Dated November 4, 1867.

This invention is not described apart from the drawings. —Patent completed.

3107 W. E NEWTON. *An improved mode of covering steel or iron plates with copper, and manner of arranging or disposing such plates.* (A communication.) Dated November 4, 1867.

This invention relates to the covering of steel with copper, and consists, first, in serrating or otherwise roughening the surface of the steel to be covered; and, second, in then placing the serrated steel plate with the copper plate in contact with such surface, and with borax or tinner's flux between the two plates, after which the two plates are placed upon a thick bed-plate of cast-iron or steel previously heated to or above the melting point of copper. This bed-plate is placed on the lower disc of the press, the upper disc of which is made hollow, and with a non-conducting substance inside. Pressure is then brought to bear, and the steel plate, by expanding under heat, the hot or melted copper will be forced into the indentations and body of the steel, and, as the steel cools, it will be closed or shut up, thus fastening the copper thereto, and producing a permanent adhesion or union of the two metals.—Patent completed.

3108 W. R. LAKE. *An improved artificial compound chiefly designed for use as a substitute for india-rubber or caoutchouc.* (A communication.) Dated November 4, 1867.

This invention consists in compounding and combining together in certain proportions, and in any suitable manner, one or more vegetable fats or oils, one or more mineral oils or resins, one or more gum resins, one or more essential or volatile oils, either with or without resins, or one or more alkalies and sulphur, and in the uniting or combining this compound with a small proportion of caoutchouc or india-rubber, or gutta-percha, or their equivalents, and vulcanizing, the same by any mode adapted for that purpose, whereby the patentee obtains a product which is characterized by the possession of the leading qualities of vulcanized caoutchouc, and also other very important qualities, and which can be manufactured in any desirable quantity, and at much less cost than the ordinary vulcanized caoutchouc.—Patent completed.

3109 W. MARSHALL. *Improvements in machinery or apparatus employed in the clipping of lace and other fabrics.* Dated November 5, 1867.

Heretofore, machinery used in clipping lace and other fabrics consisted of two, or at most three, cutting blades lying flatwise on each side of a two-edged central blade, such blades being adjustable towards or from each other. Now, in this invention, the inventor employs two, three, or more blades, each blade being capable of adjustment separately, and, moreover, he employs several sets of these blades; each set of blades will perform cutting operations at one and the same time.—Patent abandoned

3110 H. ALLMAN and F. N. GISBORNE. *Increasing the production of light from, and improving the combustion of, carburetted gases.* Dated November 5, 1867.

This invention is not fully described without reference to the drawings.—Patent completed.

3111 A. VERDALLE. *Improved means for closing doors or windows.* Dated November 5, 1867.

This invention is not described apart from the drawings. —Patent abandoned.

3112 T. WINGATE. *Improvements in anchors.* Dated November 5, 1867.

This invention relates to the making of an anchor without a stock, and the patentee is enabled to dispense with that part by making the anchor with three or more movable or jointed arms. In carrying out the invention, he prefers to use four arms, which are made in pairs, each pair being formed in one piece, which is jointed upon the shank. The invention cannot be fully described without reference to the drawings.—Patent completed.

3113 T. BRIGGS and W. E. YATES. *Certain improvements in looms for weaving.* Dated November 5, 1867.

The patentees claim, first, the arrangement and combination described of apparatus between the breast beam and the cloth roller for taking up and stretching the cloth. Second, the employment and use of a picker having a yielding or elastic surface, by which the shuttle is struck and propelled. Third, the employment and use of a movable tube of wood, metal, or suitable material, applied to support the picker, and to slide upon the shuttle box spindle; and, fourth, the general arrangement, construction, and combination of the apparatus constituting the improved picker, as described.—Patent completed.

3114 S. H. FOSTER and T. BUNNEY. *Improvements in the manufacture of looped fabric for braces.* Dated November 5, 1867.

This invention relates to the production of an improved looped fabric to be used in the manufacture of braces. For this purpose one of the guide bars which, for the sake of distinction only, the inventors call the bottom guide bar of the frame or loom, is caused to rise two needles at the same time that the other guide bar (say the top guide bar) rises one needle. Both guide bars then fall one needle. The needles are pressed, a course of loops formed, and the last-formed row of loops on the fabric is knocked over the needle heads. For the reverse course the bottom guide bar falls two needles at the same time that the top guide bar falls one needle. Both guide bars then rise one needle, the needles are pressed, and the last row of loops on the fabric is knocked over the heads of the needles as before, completing the course.—Patent abandoned.

3115 H. SMYTH. *Improvements in umbrellas, parasols, and sunshades.* Dated November 5, 1867.

This invention relates to means for effecting the connection of the ribs and the stretchers to their "wheels," as well as of the ribs and stretchers to each other, so as to obtain simplicity in the action of the parts, with other advantages. Also the improvements relate to means for effecting the locking of the runner of the stretchers either when the umbrella, parasol, or sunshade is open or closed. For these purposes the end of each rib or stretcher attached to the "wheel" is formed spherical, or with a ball at its end, and these balls or spherical ends are received into correspondingly shaped recesses or sockets formed for them in the "wheels," where they are covered and held securely by a covering ring or cap, openings being left from the recesses or sockets in the "wheels," and their caps to admit of sufficient play for the ribs and stretchers. The end of each stretcher attached to the ribs is also formed spherically, and is received between two hollow surfaces in a plate on each rib. The holding rings are retained by rivets, screws, "burnishing," or by slight soft solder, so as to be removed and replaced when required. The runner with its "wheel" connected to the stretchers is grooved to run upon a pin or feather on the umbrella, parasol, or sunshade stick, or it is provided with a pin or feather to run in a groove in such stick. A spring stop acts in corresponding recesses to hold the runner in position, either when the umbrella, parasol, or sunshade is open or closed. Stops may be used to control the extent of motions. The spring stop may be provided with a knob or milled ring.—Patent abandoned.

3116 H. ADEANE. *The protection of the eye from wind, dust, and the inclemency of the weather.* Dated November 5, 1867.

This invention has reference to an improved apparatus for protecting the eyes from wind, dust, snow, and the inclemency of the weather, and consists of a metallic frame, the upper part of which is fitted to the forehead, the middle portion projecting over the eyes, and a third or lower part declining to and resting on the nose and face, also a piece joined by means of pivots or hinges at each end of the forehead clip for the purpose of fixing the frame

Digitized by Google

to the head, and also for the adapting of the whole to various sized faces. At each side of the frame a movable stay or bracket is provided for the purpose of firmly keeping the frame extended. The frame is to be made with either pivots or hinges capable of being folded when not in use, the whole or part to be covered with gauze, net, or other suitable material, whether transparent or otherwise, for the protection of the eyes.—Patent abandoned.

3117 C. E. BROOMAN. *Improvements in reckoning, counting, or calculating apparatus.* (A communication.) Dated November 5, 1867.

We cannot here give space to the details of this invention.—Patent completed.

3118 E. C. VINE. *Improvements in stays, corsets, bodices, and riding belts.* Dated November 5, 1867.

This invention consists in the employment of one, two, or more bands, strips, or pieces of elastic substance in the stay, corset, bodice, or riding belt at or about the region of the waist, such elastic substance being attached to or combined with the stay in such manner as to form a portion or portions thereof, especially or mainly in the direction or at the circumference, of the waist, or obliquely thereto. —Patent completed.

3119 A. M. CLARK. *Improvements in railway and other brakes.* (A communication.) Dated November 5, 1867.

This invention is not described apart from the drawings. —Patent completed.

3120 R. PALMER and H. S. BIRD. *Improvements in the manufacture of wheaten flour and bread.* Dated November 5, 1867.

According to this invention, after separating the bran in the usual manner, the patentees grind it to an impalpable powder, and remix it with the white flour, and from this mixture, the whole of which is an impalpable powder, they make brown bread.—Patent completed.

3121 W. GEEVES. *Improvements in the construction of panel doors and frames.* Dated November 5, 1867.

According to this invention the patentee makes the mortices with parallel ends, and between each end of a mortice and its tenon (which is parallel, as heretofore), he inserts two keys or wedges; one he places in the key way with its broader end inwards, and he then drives the other key or wedge home upon it. On the inner sides of the tenons he forms the driven wedges considerably longer than the tenons, so that they drive into holes formed for them in the substance of the rails, and serve also as dowels.—Patent completed.

3122 W. E. NEWTON. *Improvements in steam boilers.* (A communication.) Dated November 5, 1867.

This invention consists, first, in a novel means of connecting by return pipes or bends tubes arranged in a tier one above the other over the fireplace, and containing the water to be heated, while the fire plays outside the tubes. These return pipes communicate with apertures one over the other at the ends of the tubes, and connect each tube with one above and below it, whereby a perfect circulation is kept up, and foaming is prevented and the steam kept drier. The invention also consists in attaching these return pipes to the tubes by free socket joints provided with packing and outside clamps covered and secured by stud bolts, whereby every provision is made for unequal expansion of the parts, and the return pipes are allowed to tip or twist without straining the main tubes. The invention further consists in constructing the ends of the boiler of a series of plates of square or parallelogram form fitted to or cast with each main tube, and serving, by means of apertures, to connect the main or water tubes with each other by pipes or bends. The invention also consists in a connection of cross water pipes with the main tubes by means of return pipes or bends, as aforesaid, and arranged to communicate with the tubes, or one of them, at their ends without breaking the continuity of the tubes.—Patent completed.

3123 A. V. NEWTON. *An improvement in roller or anti-friction journal boxes or bearing, applicable also to the hubs of wheels.* (A communication.) Dated November 5, 1867.

This invention has for its object the diminution of friction in bearings to axles, shafts, and wheels, or other like bodies having a rotary or turning motion about an axis, and consists in a combination of a journal box provided with a series of anti-friction rollers arranged around and within the box that, together with its rollers, is hung free to turn or rotate on or around a central axle shaft, trunnion, or gudgeon, and is surrounded externally by a box or brush having an interior bearing surface between which and the axle or shaft the rollers lie, and with both of which they form bearing contact.—Patent completed.

3124 A. M'DOUGALL. *Improvements in apparatus for stirring or agitating solid substances, and for exposing them to the action of the air, gases, and vapours.* Dated November 5, 1867.

This invention is not described apart from the drawings. —Patent completed.

3125 J. W. R. HILL. *An improved mode of, and means for, propelling rocking-horses, carriages, and other vehicles.* Dated November 5, 1867.

This invention relates to means for causing a rocking-horse, carriage, or other vehicle, to advance by its oscillating or rocking motion, the weight of the horse or carriage, together with the weight and action of the rider or operator, being the motive power.—Patent abandoned.

3126 R. LEAKE and J. BECKETT. *Improvements in machinery for polishing cylinders.* Dated November 6, 1867.

The cylinder to be polished is supported in suitable bearings, and is turned round by steam or other power. The stone or other polishing agent is held in contact with the cylinder by a weighted lever or weight, and is traversed to and fro lengthwise, and at right angles to the cylinder, by a rack and pinion and a crank, or other equivalents. By the combination of these three motions, that is to say, the rotation of the cylinder, and the to and fro motions of the stone, the surface of the cylinder is accurately polished without the aid of manual labour, as is now customary. A self-acting apparatus is or may be applied to the machine to arrest its action as soon as the cylinder has obtained the diameter required.—Patent completed.

3127 E. C. PRENTICE. *Improvements in the treatment of gun cotton and charges or cartridges made therefrom, as also in the processes employed in their manufacture.* Dated November 6, 1867.

We cannot here give space to the details of this invention.—Patent completed.

3128 T. F. CASHIN. *Improvements in apparatus for working and governing the action of railway points and signals, a part of which is applicable for other purposes.* Dated November 6, 1867.

We cannot here give space to the details of this invention.—Patent abandoned.

3129 H. A. BONNEVILLE. *A new and improved box for preserving pasty matters and substances.* (A communication.) Dated November 6, 1867.

The patentee claims the combination, with a movable diaphragm at top and bottom, actuated by an endless screw, or other suitable means, of a box or recipient, intended to preserve pasty substances, substantially as described.—Patent completed.

3130 W. E. GEDGE. *Improvements in venetian blinds.* (A communication.) Dated November 6, 1867.

This invention is not described apart from the drawings. —Patent abandoned.

3131 R. NEWTON. *Improvements in fuel feeding apparatus for steam boilers.* Dated November 6, 1867.

This invention has reference to a previous patent, dated March 24, 1866 (No. 878), and relates to the well-known feeder in which the fuel passes between toothed rollers, and is thereby triturated, when it falls upon distributors, by which means it is thrown upon the fire. To remedy the defects of the usual arrangement is the object of the present invention, and for this purpose the patentee so arranges the teeth of the crushing or triturating rollers relatively to each other, that, instead of meeting each other point to point, as is now the case, they follow each other in a manner similar to that which they would do supposing them to be in gear at the side (so to speak) of each tooth. The purport of this arrangement is to enable him to use any class of coal or coke fuel, so that in the event of "slack," say, being used, it is gradually and evenly admitted to the distributors. A further improvement consists in making the centres of the distributors (which are the well-known circular webbed discs) of a bell formation, in order that the fuel falling from the rollers above them may be pitched towards their outer edges, and thus more readily (through their rotary movement) thrown upon the furnace beneath them. The webs of the distributors he also hollows out near the shaft, to prevent any one compartment being choked.—Patent completed.

3132 I. BAGGS. *Improvements in preparing and oxidizing certain substances capable of producing chlorine.* Dated November 6, 1867.

One part of this invention consists in converting the suboxides of manganese, whether natural or artificial, and from whatever source they may be obtained, into peroxide, or in imparting a higher state of oxidation thereto than they have previously possessed.—Patent abandoned.

3133 E. and R. THORNTON. *Improvements in steam boiler and other furnaces.* Dated November 6, 1867.

This invention consists in the construction and application to furnaces of cylindrical grate bars capable of rotating on suitable framework. These grate bars are made hollow, and perforated through their crust for the passage of air. They are also provided with teeth or projections on their external surfaces, for the purpose of carrying the fuel forward in the furnace. Motion may be given to these grate bars by screws or worms and worm wheel, or any other means of producing rotary motion in the same direction, so as to gradually carry the fuel from the front to the back part of the furnace where the clinkers pass out to the ash pit.—Patent abandoned.

3134 W. PEARSON and W. SPURR. *Improvements in looms for weaving.* Dated November 6, 1867.

This invention relates to looms for weaving fancy woollen fabrics, or such as require two or more different colours or kinds of yarn to be used in their production, and for which purpose change shuttle boxes and jacquard apparatus, or other indicating apparatus, are required to be employed therewith. In the working of this class of looms various means are adopted for giving motion to the said change boxes, the indicating apparatus, and other parts of the loom, but which means are usually required to operate simultaneously, or in concert with each other, and in the process of weaving, when the weft breaks or becomes used up, the loom being heavy will continue to run for some time after without the introduction of weft, so that it becomes necessary to turn those parts back to the broken pick, or to place the several parts of the loom in the same relative position as they were when the weft broke.—Patent abandoned.

3135 J. BOTTERILL. *Improvements in the dyeing of textile fabrics.* Dated November 6, 1867.

This invention relates to the dyeing of woven fabrics composed wholly or partly of the fibre known as China grass. This fibre has naturally a lustrous appearance, but it has been found that when dyed by the ordinary methods employed in dyeing cotton goods, the lustre is lost, and the fabric is permanently creased. By the improved process the patentee avoids these defects, and adds to the lustre of the goods. In treating goods composed wholly of China grass, or of China grass and cotton, the warp being of one material and the weft of the other, he first cleanses the goods thoroughly in a warm solution of soap, taking care, by the use of rollers, to avoid the creasing of the fabric. After cleansing he suspends the goods in a stove charged with brimstone fumes, in order that they may become thoroughly saturated therewith. The sulphur thus imbibed will serve as a mordaunt suitable for fixing (say) aniline colours. The goods thus heated are then ready for the dyeing operation.—Patent completed.

3136 W. R. LAKE. *Improvements in the manufacture of waterproof fabrics, and in articles formed of the same.* (A communication.) Dated November 6, 1867.

Belting, hose, packing, and other like articles, have heretofore been manufactured by applying to woven fabrics compounds prepared for vulcanization, in which compounds either india-rubber or gutta-percha has been the principal ingredient. When the compound used consists, principally, of india-rubber, the belts or other articles are not only injuriously affected by the atmosphere in hot weather, and exposure to all artificial heats in their various uses, but are also liable to be injured and destroyed by oils, alkalies, acids, and other chemical substances. When manufactured of a compound whose principal ingredient is gutta-percha, they lack the requisite elasticity, and are liable to crack. The nature of this invention consists in applying to a woven fabric both of these compounds separately, and thereby preserving the elastic quality required in belting, hose, packing, and like articles, and protecting them against the injurious operations of heat, oils, alkalies, and acids, and against injury from other causes.—Patent completed.

3137 A. M. CLARK. *Improvements in pianofortes.* (A communication.) Dated November 6, 1867.

This invention relates to the application to grand, square, and other pianos, of an apparatus for prolonging the sound, by producing the continuous vibration of the wires. We cannot quote the details of the invention.—Patent completed.

3138 C. L. HETT. *Improvements in the governors of steam and other motive power engines.* Dated November 7, 1867.

This invention relates to centrifugal or ball governors, and it consists in so connecting the suspension rods and links to the vertical shaft that the path of the balls as they expand from an approximate parabolic curve, instead of the arc of a circle, as usual, and, consequently, the sliding bush and rod connected to the throttle valve or cut-off gear is moved to the required extent with the slightest variation in the speed of the engine to be governed.—Patent completed.

3139 T. R. BARDSLEY and W. BLACKSHAW. *Improvements in apparatus for smoke consuming in steam boiler and other furnaces.* Dated November 7, 1867.

This invention has for its object the consumption of smoke in steam boiler furnaces by the introduction of heated air at the back of the bridge, which, mixing with the smoke, is immediately converted into ignited gas, the extra heat thereby produced being at once communicated to the boiler, and this invention consists in the use and application of a tube formed of metal, fireclay, or other suitable material carried from the rear of the boiler (where a damper may be applied to its end) into the metallic tubular flue, or through the brick flues round the boiler, and thence through the metallic tubular flue, where it may open into a cavity formed at the back of the bridge, which cavity has a narrow opening into the flue at the back of the bridge, which may or may not be covered with an overhanging top to prevent soot falling into the cavity, and thus choking it up. The action of this apparatus may be thus described:—By means of the draught in the flues, atmospheric air is caused to pass through the metallic or other tube into the cavity at the back of the bridge, which, becoming heated and rarefied in its passage, is in the proper state to be mixed with the smoke in the flues, and the quantity of air admitted may be regulated by a self-acting damper, so that when the furnaces are freshly fed, a greater quantity of air may be supplied, which may again be reduced gradually until entirely cut off by self-closing mechanism applied to the damper.—Patent completed.

3140 T. J. BAKER. *Improvements in the manufacture of wheat and other grain into flour, and in the machinery connected therewith.* Dated November 7, 1867.

These improvements consist under one head in forming an air and moisture trap in the meal spout, by inserting therein, in a suitable case, a wheel having vanes at short distances around it, and moving at a slow velocity, the case at one side being open into the meal spout both above and below, the connection between the top and bottom of the spout being cut off by the vane wheel, so that, as the meal or products of the grinding descend in the spout, they are caught by it and permitted to advance only at the rate, and in the direction of, the said vane wheel. The patentee gives the before-mentioned vane wheel motion in direction contrary to the descending meal, so that the meal is, by its action, first heaped upon one side of the meal spout, and the passage sealed against the descent of air and moisture, and is then carried round the top of the wheel, at a velocity so slow as to seal the passage at the other side of the case, and around the top, against the escape of air and moisture.—Patent completed.

3141 E. SEPHTON. *Improvements in the construction or arrangement of blocks of so-called workmen's dwellings.* Dated November 7, 1867.

Here the outer walls of each block of dwellings are of any desired outline in plan, and the rooms are arranged and set apart to suit the proposed class of tenants. The entrances from the street are by passages or covered ways to the back of the block, where corridors and staircases common to the tenants branch off. The staircases lead to terraces running along each floor at the back of the building, and from the terraces the doors of the respective tenements open, each tenement being preferably so arranged that one half of the apartments have light from the front of the block, and the other half from the back thereof. At certain distances, say each tenth or twelfth dwelling, a vertical shaft to receive ashes and other waste rises upwards through the terraces. Folding doors or traps are fitted to the said shaft on each terrace, and when water-closets are not provided in each dwelling, they are placed around or near the shaft.—Patent completed.

3142 W. J. M. RANKINE. *Improvements in apparatus for obtaining uniform rotation.* Dated November 7, 1867.

This invention consists of improvements on the instruments commonly called governors, in which a load and the centrifugal force of a revolving mass or masses act in opposition to each other, so that as one or other of their forces preponderates, the arm or arms carrying the revolving mass or masses shift their position in one direction or the other, so as to act on the motive power by means of a regulating valve, or other suitable apparatus. The defect of the ordinary governor is that the speed of rotation at which the balance between load and centrifugal force takes place varies with the position of the arms. In order that such balance may take place at one uniform speed only for a given load, the load is made to act upon a lever or levers so connected with the arms carrying the revolving masses that during any change of position the levers acted upon by the load move through double the angle that is moved through by the arms carrying the revolving masses. The speed at which the balance of load and centrifugal force takes place can be varied at will by altering the load, but not otherwise. The load may constitute either of a weight or weights, which must be distinct from the revolving masses, which exert centrifugal force, or of the elasticity of a spring. In one arrangement for carrying the invention into effect two rods with balls at their four ends are jointed at their middles to a vertical spindle, so as to be capable of moving about the joint in vertical planes passing through the spindle. Two short levers are jointed to the spindle at a point the distance of which below the joint of the ball rods is equal to the length of those short levers, and their ends are fitted to slide upon the lower parts of the ball rods, with which disposition of the parts it follows that the short levers must always move through double the angle moved through by the ball rods. The rods with the balls are balanced as

Digitized by Google

regards gravity, but are free to assume different positions under the influence of centrifugal force. If the load to oppose centrifugal force is to be obtained by means of a weight, such weight may be in the form of a ring concentric with the spindle, and freely suspended by links or otherwise to any convenient parts of the short levers; or the load may be produced wholly or partly by a weight adjustable on a lever acting on a collar on the spindle, such collar being connected to the short levers.—Patent abandoned.

3143 C. H. BRIGHT. *Improvements in tramways or railways for streets or roads, and wheels adapted to run thereon.* Dated November 7, 1867.

At the level of the surface of the street or road to which a tramway or railway is to be applied, the patentee places a bar or flat rail (one rail being used for each side of the railway or tramway, as usual), and he secures the same upon and to suitable sleepers by screws or spikes, the bars or rail being so laid or placed that, in its transverse direction, it shall slant off from the central line of the way between the rails, which arrangement or construction is specially adapted for the transit of wheels with peripheries corresponding to the slant or angle of the rails, namely, constructed with tires or peripheries, one portion of which (that is, the portion which is on the inner side of the wheel) is bevelled off to suit the angle at which the aforesaid bar or rail is placed; and, further, these tires may be constructed as compound tires, that is, in two parts, the flat circle or periphery, which is intended for running on the ordinary roadway, being in one part, and the bevelled portion of the said circle or periphery, which is to run on the rail, being the other, this latter portion being bolted to the aforesaid flat part, or otherwise securely attached thereto.—Patent completed.

3144 C. H. BRIGHT. *Improvements applicable to carriages for tramways or railways for streets or roads.* Dated November 7, 1867.

Here the inventor constructs the carriages abovementioned with the fore wheels arranged and acting on the bogie system with provision for "locking" the same by means of a cam or bolt put into and out of action by the agency of a handle or foot lever worked by the driver of the carriage or other attendant, in order that when the wheels are working on the rails the "locking" thereof may aid in the retention of the carriage on the line. These carriages provide with friction breaks arranged two for each wheel, so that the periphery of the same may be gripped by two breaks acting perpendicularly opposite each other, such breaks being put into and out of action by means of screwed shafts or rods, or other similar gearing worked by a handle or handles (two being preferred, one for the driver and the other for the conductor), in order that the one may assist the other for greater efficiency of working.—Patent abandoned.

3145 E. SACRE. *Improvements in the construction of armour for the defence of ships, forts, batteries, and other constructions.* Dated November 7, 1867.

These armour-plates are formed of two plates of wrought iron produced by either rolling, hammering, or in any other convenient manner. These plates are to be secured together by means of bolts, but before so doing the inner sides have semicircular grooves formed on them. Or these grooves may be of any other form that might be found necessary. The intervening spaces formed by these grooves are to be filled with cast iron chilled or otherwise, or of any other hard material. These grooves are placed so close together that there will not be space enough for a shot to pass between them, and as the hard metal contained in the grooves which run vertically (and if desired horizontally also) will be as hard as the projectile there will be sufficient resistance to stop the shot.—Patent abandoned.

3146 B. T. NEWNHAM. *Improvements in means or apparatus to be used in playing games.* Dated November 7, 1867.

This invention is not described apart from the drawings. —Patent completed.

3147 I. HEWITT. *An improved machine for forming, printing, and counting labels.* Dated November 7, 1867.

This invention relates to the construction of a machine for manufacturing in a more perfect and expeditious manner than has hitherto been found practicable plain or printed labels for addressing parcels and luggage, and for medical and other purposes. The invention consists chiefly in the devices and apparatus for printing, folding, punching, cyclelting, dividing, and counting the said labels; in the means for supplying the strips of paper or other material to the machine; and in the combination therein of the said devices and apparatus, whereby the strip is fed into the machine, and the labels delivered from the same in a perfect or finished condition. We cannot here quote the details of this invention.—Patent abandoned.

3148 J. F. BRINJES. *Improvements in apparatus for distilling, heating, evaporating, and cooling liquids.* Dated November 7, 1867.

The patentee claims, first, the combination of two or more rotary distilling vessels or chambers, situate one above another, and connected by pipes with each other, and with separate condensers, the whole being arranged and operating substantially as described. Second, the combination of two or more rotatory vessels or chambers for evaporating and heating liquids, substantially as described. Third, the application and use to, and in the cooling of liquids, of one or more rotatory vessels or chambers, arranged and operating substantially as described.—Patent completed.

3149 J. WHEELER. *Improvements in gloves.* Dated November 7, 1867.

This invention has reference to what are called the welts of kid and other like gloves, and consists in extending the welts without any join entirely round the upper part of the glove, and along the sides of the opening in front, the said welt commencing and terminating at the bottom of such opening or otherwise, in which case the said opening is strengthened at the bottom whilst all seams and multiple thicknesses or folds of material at the corners are avoided. Or the welt may be joined only at the two sides of the front opening just below the button and the button hole or other fastening. The corners are curved or rounded in lieu of being left square or pointed, as at present, whereby a neater appearance will be imparted to the glove. If desired, the patch or covering which is usually stitched over the back of the button or fastening may be made in one piece with the inner portion of the welt.—Patent completed.

3150 R. ROBINSON. *Improvements in the manufacture of filtering paper.* Dated November 7, 1867.

According to this invention the patentee strengthens filtering paper by embedding in its substance in the process of manufacture threads or cords, which may either be separate the one from the other, or woven or netted into a loose and open fabric. It is not essential that the threads or cords or fabries should be entirely enclosed in the paper so long as a secure adhesion is obtained.—Patent completed.

3151 T. CLARK. *Improvements in the permanent way of railways.* Dated November 7, 1867.

In constructing the permanent way of railways where double-headed rails are used, the ends of the rails are usually cut off square, or at right angles to the length of the line of railway, so that the wheels pass suddenly from one rail to another, and an uneasy motion is the result. Now, according to this invention, the patentee cuts off the ends of the double-headed rails in a direction inclined to the length of the line of railway, and he connects the ends so cut off with fish-plates secured by bolts and nuts, and the fished joints so formed are placed intermediate of the chairs by which the line of railway is supported.—Patent completed.

3152 T. BLACKBURN. *Improvements in looms for weaving.* Dated November 8, 1867.

The nature of the invention consists, first, in certain improved combined letting-off and taking-up motions. Second, in certain improved modes of working the vibrator to slacken and tighten the warp. Third, in the application of an indicator to register the length of warp let off the warp beam. Fourth, in certain improvements in the taking-up motion; and, lastly, in covering the letting-off and taking-up rollers of the letting-off and taking-up motions above referred to with cloth prepared with a solution of india-rubber, or any preparation of india-rubber.—Patent completed.

3153 C. ANDERSON. *Improvements in apparatus for regulating or adjusting the position of endless travelling webs or bands employed in various kinds of machinery.* Dated November 8, 1867.

For the purposes of this invention a guiding roller, which is supported at each end on a framing having suitable bearings, is used; the web or band rests on and passes over this roller, and, when at work, gives it a revolving motion immediately underneath; and stretching across the web or band, but clear of it, is a rod which is supported at each end on small levers fitted to a stud on the framing or other suitable place; near the end of this rod is fixed a metal blade close to but clear of both edges of the web or band. The bearings of the conducting rollers consist of a box-shaped bracket with a brass brush fitted and working into it, so that it may slide either way by the action of a screw shaft fitted into the box bracket and passing through the under side of the brass brush. The screw shaft has bearings at each end of the box bracket, and has small bevel pinions keyed on each end on one side of the bracket, and towards each end are fixed round studs on which is fitted to run loosely bevel pinions gearing in to the wheels. The pinions on the side are cast with long square necks, and are kept in their places by cotters fixed on the end of the studs. On these square necks ratchet wheels are fitted with square eyes, and the ratchet wheels are connected by a suitable clutch to a double lever having a centre bearing on a stud, which is fixed vertically on a suitable projection cast or fitted on the centre of the box bracket. To one end of the double lever the wooden rod is fixed, and on the spindle of the conducting roller is fixed a bevelled plate. When the web or band is in its true position, the ratchet wheels are set so that they clear without touching the bevelled plate.—Patent completed.

3154 I. M'KIMM. *An improved apparatus for indicating horizontal, vertical, or any angular or inclined line, position, or surface.* Dated November 8, 1867.

This apparatus consists of a metallic base-plate which is truly bevelled, so as to be applied to any line or surface. At the central part of the metallic plate an upright projecting piece is situated, and through which a hole is formed to receive a circular stud, which can be rotated therein, the outer end of this stud carrying a box containing a spirit level, whilst to the opposite end an index plate is fixed. The extreme end of the stud on which the index plate is fixed has a screw formed on it over which a thumb nut is placed, and the body of the nut is made slightly conical so that the index plate may at any time be firmly fixed, and accurately adjusted thereon. The periphery of the index plate is cut with teeth, and a retaining catch or spring is fixed to the base-plate with a tooth on it, which fits into the spaces between the teeth on the plate, so that, by depressing the catch, the level may be shifted to occupy any angle in either a right or left-hand direction; a stop is also placed on the under side of the one end of the box containing the level tube, and its end rests upon an adjustable screw, so that the accuracy of the instrument can at any time be fixed by placing it on a level surface, and adjusting the screw until the level stands in a central position, whether the instrument be applied to a truly horizontal or truly vertical surface.—Patent abandoned.

3155 J. W. SMITH and T. PETITJEAN. *Improvements in warming, ventilating, and heating apparatus.* Dated November 8, 1867.

Provisional protection has not been granted for this invention.

3156 H. JEWITT. *A revolving apparatus for exhibiting figures and other objects in apparent motion.* (A communication.) Dated November 8, 1867.

This apparatus consists of a stand with a hollow central column in which revolves a spindle of iron or other metal. This spindle is screwed or otherwise fastened into a hollow cylinder of cardboard, tin, or other suitable material. Inside the said cylinder are placed sheets of paper having figures or other designs printed, drawn, or painted thereon; the said cylinder has slits or perforations around its circumference, and, on rotary motion being imparted thereto, the figures or other objects on the inside appear in apparent motion.—Patent abandoned.

3157 G. W. R. PIGOTT. *Improvements in covering wire with metal or other material.* Dated November 8, 1867.

This invention relates to means and apparatus for covering or coating wire with tin, zinc, or other suitable metal or material, when in a state of fusion or liquefaction. We cannot here quote the details of the invention. —Patent completed.

3158 S. LANDELLS. *Improvements in the manufacture of glass globes and other hollow forms for gaseliers, chandeliers, candles, lamps, and other similar purposes.* Dated November 8, 1867.

This invention is not described apart from the drawings. —Patent abandoned.

3159 W. INGLIS. *Improvements in shaft couplings.* (A communication.) Dated November 8, 1867.

This invention has for its object the coupling together of lengths of shafting in an improved manner without rigidly bolting them to each other, but so as to form a strong and simple coupling possessing the peculiarities and advantages of what is generally known as a universal joint, and it consists in forming the end of each shaft, or a piece fixed thereon, with lugs or teeth projecting parallel to the shaft, and in placing angular or wedge-shaped blocks in the spaces which occur between the teeth when the two shafts are put together. The annular blocks may be held in position by means of an external encircling band or hoop and annular plates connected by bolts passing through the blocks, or in an equivalent manner.—Patent completed.

3160 P. H. NATHAN. *Certain improvements in printing or producing patterns or designs on woven fabrics.* (A communication.) Dated November 8, 1867.

Provisional protection has not been granted for this invention.

3161 T. WRIGLEY. *Certain improvements in the permanent way of railways.* Dated November 8, 1867.

This invention consists in the application and use of two plates, which are bolted to each side of the main rail, and which are each provided at the extremities near the junction of the rail with swellings or projections of semicircular form; two other plates are bolted to the switch rail, and the projecting ends are curved, so as to embrace, and partly encircle, the semicircular ends of the other plates, which constitutes a union similar to a "ball and socket joint," within which the rail and switch are grasped, and on which the switch moves; thus the switch is firmly held by the novel adaptation of fish-plates, and yet is capable of being moved from side to side on its joint or unions, and the plates being screwed closely to the rail and switch, no aperture is left for the accumulation of dirt and cinders, which often prevents the close contact of the switch with the rail.—Patent abandoned.

3162 S. A. KIRBY. *Improvements in paraffin and other lamps.* Dated November 8, 1867.

The object of this invention is to prevent overflow or leakage, and the inventor accomplishes this purpose by attaching the wick-holder and other part of the lamp to the reservoir in such a way that any drops of oil which escape during the burning of the lamp are carried back into the reservoir. This is done either by constructing the wick-holder and cap so that they shall not extend beyond and overhang the neck of the reservoir, or by forming the reservoir with a lip so constructed as to catch the said drops of oil.—Patent abandoned.

3163 W. CHIPPINDALE. *Improvements in apparatus employed in coupling railway carriages.* Dated November 8, 1867.

In the specification of a former patent granted to the present patentee, January 3, 1867 (No. 18), was described apparatus for acting on the coupling links of railway carriages by levers or handles placed at the sides of the carriages to render it unnecessary for men to stand between the carriages or between the rails when coupling-up or uncoupling railway carriages. The present invention has for its object the so constructing apparatus of this description that it may be made at a less cost, and also that it may allow of using the old coupling chains. In order to hook the coupling chain or link carried at the centre of the end of one carriage over the draw hook at the centre of the end of the carriage next to it, he now proposes to construct the apparatus in the following manner:—The coupling chain or link is carried by the draw-bat at the centre of the end of the carriage, as is usual; below the drawbar is carried a slide, capable of sliding lengthwise of the carriage, the end of this slide projecting beyond the carriage, and carries a short horizontal axis on which are formed two arms, which ordinarily hang down below the carriage; the lower ends of the arms are suitably formed for taking hold of the end link of the coupling chain. At a short distance below the horizontal axis above mentioned each of the arms has pin-jointed to it one end of a horizontal lever, and the se levers pass respectively, the one to one side and the other to the side of the end of the carriage. Near the side of the carriage each lever is carried by a bear, which forms the vertical pivot upon which the lever turns. These bearings are so formed as to allow of the levers being turned on their own longitudinal axis, and the levers at their outer ends are each formed with a cranked arm, by which they can be thus turned. When either one or the other of the levers is thus turned on its longitudinal axis, the arms hanging down from the central slide, and to which the levers are jointed, are raised to a horizontal position, and their ends carry with them the end link of the coupling chain. If the levers are then caused to turn on their pivots, the slide to which the inner end of the lever is jointed is slid forward and caused to project further from the end of the carriage. The arms carrying the end of the coupling chain are thus also moved away from the end of the carriage, and carry the end of the coupling chain over and beyond the draw-hook at the end of the next carriage. By then allowing the arms to turn downwards, the coupling chain will be hooked on to the draw-hook, and the coupling may afterwards be tightened by shortening the length of the drawbars of the carriages, as described in the specification before mentioned. The bearings which form the pivots of the levers are connected by links to the ends of the carriage, or are otherwise formed to permit of the levers being caused to move forward the slide to which their ends are jointed.—Patent completed.

3164 G. T. BOUSFIELD. *Improvements in machinery for setting types.* (A communication.) Dated November 8, 1867.

This invention is not described apart from the drawings. —Patent completed.

3165 J. E. CASTEX. *Improvements in harmonium-piano.* (A communication.) Dated November 9, 1867.

This invention is not described apart from the drawings. —Patent abandoned.

3166 S. HALL and M. WHITTINGHAM. *Improvements in locks.* Dated November 9, 1867.

This invention is not described apart from the drawings. —Patent completed.

Digitized by Google

3167 H. ELLIS. *Improvements in the manufacture of parasols.* Dated November 9, 1867.

This invention consists, principally, in manufacturing parasols with straight ribs, and in cutting the gores of the silk or material with which such parasols are covered with straight (instead of curved) sides, so that, when the parasol is opened, it presents the form of a flat disc, or a very slightly conical shape, instead of the ordinary mushroom or pagoda form.—Patent completed.

3168 E. B. WILSON. *Improvements in furnaces.* Dated November 9, 1867.

This invention is applicable to flued boilers, and to marine boiler furnaces. When altering a flued or Cornish boiler furnace, the inventor constructs a perforated brick arch at the higher part of the flue, with a space between the arch and the top of the flue for supplying the perforations with air; the air so supplied passes down on to and into the incandescent fuel. Or he constructs the arch with segments of fireclay perforated.—Patent abandoned.

3169 J. GRESHAM. *Improvements in, or applicable to, that apparatus known as Giffard's injector, and in the method of, and machinery or tools for, making the same.* Dated November 9, 1867.

These improvements relate, first, to a new combination and arrangement of the parts of injectors, by forming two screw threads upon the central spindle, one of which threads screw through a fixed part or collar, and the other into a screw thread formed in the interior of the ram or part to which the steam nozzle is attached, so that, by turning the central spindle a double adjustment is obtained, that is, by turning one way, the steam nozzle will be made in one direction to shut or reduce the water space, and the cone spindle will be made to move in the opposite direction, to open or increase the steam space, and *vice versa*, by turning the other way. Or, according to another arrangement, the screw threads upon the central spindle will act to cause both the steam nozzle and cone spindle to move in the same direction, to open and increase the spaces for water and steam, or diminish and shut these spaces. The screw threads in this case are arranged so that the spindle will have greater end movement than the steam nozzle. The two screws upon one spindle for the double adjustment of the spindle and steam nozzle are applicable to those injectors where the steam is admitted directly into the ram to which the steam nozzle is attached, also to those injectors in which the steam is first admitted into a pipe in which the ram for the steam nozzle slides, packing being used round the ram to prevent the passage of steam to the water space. The two screws upon one spindle for the double adjustment of the steam and water are also applicable, according to the invention, where the steam nozzle is fixed and the combining and receiving cones or nozzles are adjustable; motion is conveyed from the external screw upon the spindle by outside rods to the combining and receiving cones. By the improvements above described, both the spaces for water and for steam will be adjusted by turning one handle. The improvements under this head also relate to a mode of conveying steam to the moving external steam ram (carrying the steam nozzle) of an injector, and it consists in making a short branch from the moving ram, terminating in a line with the axis of the ram, and this termination of the branch passes into a steam pipe, through a stuffing box, which permits the movement of the ram. This part of the invention also relates to the arrangement and construction of injectors. It consists in dispensing with the central cone spindle adjustment, and in making the sectional areas for steam and water where they combine of an oval or oblong form (thus exposing more surface to the condensing action of the water), and in making the water space adjustable. This part of the invention also relates to the arrangement and construction of injectors without adjustment, for either the water or steam spaces, or with a simple adjustment for the water space, where the combining and receiving cones are formed solid with the body part of the injector, and the steam nozzle is formed by a pipe screwed in a flange and without a central cone spindle. This pipe is placed either in a line with the axis of the injector, or passing in from one side, being curved to cone into the axis of the injector. The invention cannot be fully described without reference to the drawings.—Patent completed.

3170 S. SIMON. *Improvements in the manufacture of aprons, bibs, and pouches, for the use of children and infants.* (A communication) Dated November 9, 1867.

This invention consists in making aprons, bibs, and pouches, for the use of children and infants, of leather or American leather cloth, or other like impervious and damp-resisting materials or fabrics.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated March 2, 1868.

704 H. Wilson, Stockton-upon-Tees, Durham. Improvements in meters, valves, and cocks, for measuring, regulating, and discharging liquids, gases, and fluids.

Dated March 16, 1868.

889 F. H. and C. A. Elliott, Strand, opticians. Improvements in telescopes. (A communication.)

Dated March 21, 1868.

960 I. S. Lister, Laurence Pountney-hill, City. Improvements in hats and other coverings to the head, to obtain ventilation and comfort in wear. (A communication.)

Dated March 24, 1868.

1004 R. Smith, jun., Belper, Derbyshire, miller. Improved apparatus or machinery for scouring and hulling grain and seeds.

1005 M. P. W. Boulton, Tew Park, Oxfordshire, and J. Imray, Westminster Bridge-road, Surrey, engineer. Improvements in means and apparatus for effecting aerial locomotion.

Dated March 25, 1868.

1010 A. B. Wollaston, Chislehurst, Kent, merchant, and F. Stanbridge, Llangarron, Herefordshire, farmer. Improvements in the treatment of mixed fabrics, and in the separation of wool from cotton and other substances contained therein.

Dated March 27, 1868.

1046 S. Holman, Laurence Pountney-lane, City, engineer. Improvements in the construction and application of steam pumps, parts of which improvements are also applicable to other pumps, blast engines, exhausters, and other machines, also improvements in hydraulic lifts, and the mode of working the same.

Dated March 31, 1868.

1092 J. Lent, Berlin, Prussia, engineer. Improvements in electric telegraphs, and in apparatus connected therewith.

Dated April 4, 1868.

1145 C. E. Turnbull, St. Paul's-crescent, Camden-square, Middlesex. Improvements in paper binders or eyelets, and in means or apparatus for fixing together papers and other articles by means of such and other paper binders or eyelets.

Dated April 11, 1868.

1216 A. Barclay, Kilmarnock, Ayrshire, engineer. Improvements in apparatus to be used in condensing steam in steam engines, applicable also to other purposes.

Dated April 13, 1868.

1220 R. Ridley, Birmingham, engineer, and J. Rothery, Waterloo Main Colliery, near Leeds, colliery viewer. Improvements in machinery or apparatus for getting and hewing coal, stone, and other minerals.

Dated April 16, 1868.

1244 C. Burns, Middle Scotland-yard, Westminster. An improved mode of, and means for, propelling or shunting carriages and goods trucks on locomotive railways, and especially at railway stations.

1246 E. A. Morgan, Paisley, Renfrewshire, thread manufacturer. Improvements in the manufacture of the glass rings employed in spinning, twisting, and thread making machines of the class commonly known as ring and traveller throstles.

Dated April 22, 1868.

1313 T. L. Scowen, Allen-road, South Hornsey, Middlesex. An improved method of fastening the button boot without the use of button-holes.

Dated April 24, 1868.

1342 T. T. Macneil, Cockspur-street, Charing-cross. Improvements in apparatus for indicating the distances travelled by cabs and other vehicles, also applicable to the indicating of the fares payable for the distance travelled.

1344 J. R. Johnson, Red Lion-square, Middlesex. Improvements in repeating firearms.

1346 D. C. Lowber, Southampton-buildings, Chancery-lane. An improved wire tie for securing bales of cotton or woollen goods and other merchandise.

1349 J. Wetherilt, Chapel-street West, Mayfair, Middlesex, ironmonger. Improved apparatus for scoring or marking at billiards or other similar games.

1350 W. H. Ryland, Birmingham, manufacturer and factor. Improvements in fastenings for articles of dress and jewellery.

1351 J. Dewar, Kirkcaldy, North Britain, doctor of medicine. Improvements in making and preserving manure.

1352 W. Bartram, Sheffield. Improvements in the manufacture of cartridges.

1353 W. Bartram, Sheffield. Improvements in apparatus for filling, closing, and re-capping cartridges.

1354 G. A. Welch, Sydenham, Kent, Paymaster Royal Navy. Improvements in apparatus for the preservation of life and property at sea.

1355 J. Bernard, Salisbury-street, Strand. Improvements in preparing and dressing ores and minerals, and in the machinery or apparatus employed therein.

Dated April 25, 1868.

1356 T. F. Cashin, Sheffield. Improvements in apparatus for actuating and regulating the working of railway signals and the points and switches of rails (a part of which is applicable for other purposes), and also in the mode of fish-jointing rails.

1357 W. N. Hutchinson, Wellesbourne, Devonshire, Lieut.-General in her Majesty's Army. Improvements in apparatus for receiving and absorbing or checking the recoil of ordnance.

1358 G. Marson, Eagley, Lancashire. Certain improvements in the method of, and means for, retaining the outer ends of tapes, ribbons, and other similar narrow fabrics and paper.

1359 J. Craven, Thornton, Yorkshire, shawl manufacturer. Improved means or apparatus for producing the barrel fringe or tassel fringe on shawls.

1360 J. and R. Holding, Wheelton, Lancashire. Improvements in heald employed in looms for weaving.

1361 P. Spence, Newton Heath, Manchester, manufacturing chemist. Improvements applicable to the purification of gas used for illumination.

1362 A. W. Pocock, Pimlico. Improvements in working valves of steam and other engines.

1363 R. Cocker, Cockspur-street, Charing-cross, Westminster, publisher of the "Scientific Review and Journal of the Inventors' Institute." Improvements in purifying, seasoning, and preserving wood, and making it water and fireproof. (A communication.)

1364 C. Drake, Renfrew-road, Kennington. Improvements in constructing concrete buildings, and in apparatus used therein.

1365 A. M. Clark, Chancery-lane. Improvements in steam generators and furnaces. (A communication.)

1366 A. Parkes, Birmingham. Improvements in the manufacture of varnishes.

1367 J. Atkins, Birmingham, merchant. Improvements in ornamenting sheets or plates of metal.

1368 T. Pemberton, brass founder, and T. Hughes, brass finisher, Birmingham. Improvements in supports for fire-irons.

1369 F. C. Hills, Chemical Works, Deptford, Kent. Improvements in the manufacture of gas, and in the purification of gas liquor, and in utilizing gas, tar, and crude hydrocarbon oils, and in furnaces for effecting the combustion of the said gas, tar, or hydrocarbon oils.

Dated April 27, 1867.

1370 E. P. H. Vaughan, Chancery-lane. Improvements in telegraphy, and in the construction and arrangement of apparatus for communicating signals and intelligence. (A communication.)

1371 J. Hepworth, Wakefield, boiler maker, and G. W. Payldon, Calder Grove, near Wakefield, Yorkshire. Improvements in boilers and furnaces.

1372 S. Tidmarsh, Birmingham, manager of works. Improvements in locks.

1375 P. Nisser, Minories, City. An improved explosive compound or safety blasting powder.

1376 K. V. Barnekov, Newburgh, New York, U.S., civil engineer. Improvements in breech-loading firearms.

1377 H. Chaytor, Witton Castle, near Darlington, Durham. Improvements in the rolling stock of railways.

1379 L. Perkins, Seaford-street, Gray's Inn-road, engineer. Improvements in the manufacture of wrought metal wheels.

1380 J. Scofforn, New North-street, Finsbury, M.B. Improvements in sheathing ships' bottoms, and other surfaces exposed to the action of sea water.

1381 L. Perkins, Seaford-street, Gray's Inn-road, engineer. Improvements in tubular steam boilers.

Dated April 28, 1868.

1382 E. M'Donnell, Wallington Lodge, Fareham, Hampshire, civil engineer. An impervious concrete or cement.

1383 J. Pearson, jacquard harness maker, and M. Pearson, overlooker, Thornton, Yorkshire. Improvements in jacquard engines.

1384 G. T. Bousfield, Loughborough Park, Brixton, Surrey. An improved manufacture of hair seating, and for improvements in the mode of seaming or joining hair seating and other woven fabrics with a hair face, and strengthening the goods, and facilitating the upholstering of the same. (A communication.)

1385 G. A. Cox, Lochee, Dundee, Forfarshire, jute and flax spinner. Improvements in carpets, sackings, checks, bed-ticks or ticklings, and other similar textile fabrics.

1386 A. Jack, jun., Maybole, Ayrshire. Improvements in reaping machines.

1388 A. Dietz, New York, U.S., glue manufacturer. An improved method or process of treating or preparing and refining glue.

1389 H. Waugh, Whitefriars, City, civil engineer. Improvements in apparatus for screening or separating grain, seed, and other matters.

1390 W. Whitworth, Leeds, machine maker. Improvements in sewing machines.

1391 E. A. Rippingille, Holborn-hill. Improvements in obtaining motive power, and in means or apparatus employed therein.

1392 J. Bottomley, Laister Dyke, Yorkshire. Improvements in umbrellas and parasols, and in appliances to be used in connection therewith.

Dated April 29, 1868.

1393 G. B. Babacci, Florence, Italy. Improvements in gas engines.

1395 J. Gray, Glasgow. Improvements in coatings or coverings for preventing the fouling to which ships and other structures are liable in sea water.

1399 C. D. Fox, Spring-gardens, Middlesex. Improvements in machinery for nicking and dressing the heads of screw planks. (A communication.)

1401 J. J. Long, Glasgow. Improvements in machinery, processes, and apparatus to be used in the manufacture of matches and other similar articles.

1402 J. M'Kean, Walmer Bridge, Lancashire, manufacturer, and J. Stenhouse, Rodney-street, Pentonville, Middlesex, chemist. Improvements in the manufacture or preparation of materials for sizing or dressing yarns and textile fabrics.

1403 H. Deacon, Appleton House, Appleton, Lancashire, alkali manufacturer. Improvements in the manufacture of chlorine.

1404 R. Scott, Edinburgh. Improvements in apparatus for dressing millstones.

1405 J. H. Johnson, Lincoln's Inn-fields. Improvements in preserving meat and other animal matters. (A communication.)

1406 R. Heathfield, Birmingham, manufacturer. Improvements in machinery for the manufacture of cut nails. (A communication.)

1407 A. Homfray, Witley Lodge, Halesowen, Worcestershire. Improvements in the manufacture of iron or steel shackles, swivels, hooks, slips, and other kinds of iron or steel fastenings welded into an eye shape, and in machinery to be used in the said manufacture, which improvements are also applicable to the manufacture of the tyres of wheels.

Dated April 30, 1868.

1410 W. Ferrie, Monkland Iron Works, Lanarkshire. Improvements in blast furnaces.

1414 J. H. Cassell, Burdett-road, Limehouse, Middlesex. Improvements in sheathing iron ships.

1420 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for spinning fibrous materials. (A communication.)

1422 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of gelatine. (A communication.)

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated May 6, 1868.

1485 A. C. Henderson, Charing-cross. Improvements in the mode of manufacturing albumen, and in the apparatus connected therewith. (A communication.)

Dated May 11 1868.

1538 J. B. Kingham, Dorchester, Norfolk county, Massachusetts, U.S. Improvements in nail machines.

1539 A. Holbrook, jun., Lynn, Essex, Massachusetts, U.S. A machine for sewing books.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," May 19, 1868.

38 G. Platts, W. Tate, and W. H. Bailey. Apparatus for laying fog signals on railways.

42 J. R. T. Mulholland. Bobbin holder.

43 J. Combe. Machinery for balling yarn.

52 J. Maury. Connecting the ends of metallic strap applied to bales of cotton.

53 W. T. Tongue. Lamps.

55 G. Smith. Apparatus for lubricating machinery.

56 J. B. Dunn. Buckle or tie for connecting the ends of metallic straps applied to bales of cotton.

61 J. L. Norton and W. H. Bailey. Apparatus for indicating the fluctuations of the pressures of liquids.

64 P. Spence. Roasting copper and other ores containing sulphur.

73 W. H. Bailey and J. W. Lowther. Lubricating tallow cups.

75 R. Girdwood. Bags for transmitting samples by post.

81 J. Petrie. Brats or travelling surfaces for conveying wool out of washing machines.

86 C. H. Newman. Manufacture of unfermented malt liquors.

87 S. G. Archibald. Preparing tablets for receiving writing.

90 O. H. M'Mullen. Mashing machine.

93 J. H. Glew. Manufacture of boots and gaiters.

101 C. S. Lennon. Shirt fronts.

105 W. W. Hooper. Apparatus for giving signals on board ship.

Digitized by Google

121 W. E. Gedge. Breech-loading firearms. (A communication.)
125 J. C. Ramsden. Mechanism of looms for producing a certain class of fancy fabrics.
129 W. E. Gedge. The substitution of thin movable blades of sheet steel in lieu of rigid blades in planing machines. (A communication.)
133 D. Hodgson and J. Dodd. Machinery for cutting grass.
181 H. A. Bonneville. Ribbon looms. (A communication.)
225 C. E. Brooman. Mode of producing a colouring matter. (A communication.)
227 C. E. Brooman Extracting colouring matter from madder. (A communication.)
288 H. A. Bonneville. Ribbon looms. (A communication.)
291 C. E. Brooman. Manufacture of candles. (A communication.)
295 T. Corbett. Machinery for cleaning grain.
318 J. H. Johnson. Disintegrating raw wool. (A communication.)
323 H. Aland. Rotary blowing fans.
422 W. R. Lake. Locks. (A communication.)
473 A. F. Bayford. Apparatus for facilitating the watering of plants.
536 W. E. Newton. Material for the base of artificial teeth. (A communication.)
788 J. Campbell. Floating docks.
943 H. Chamberlain, J. Craven, and H. Wedekind. Burning bricks. (Partly a communication.)
1030 M. B. Orr. Apparatus for drying animal substances. (A communication.)
1229 A. and L. Braham. Hats.
1256 W. Gorman. Manufacture of iron and steel.
1337 J. Casson. Machinery for sawing wood.
1351 J. Dewar. Making manure.
1358 G. Marson. Means for retaining the outer ends of tapes.
1364 C. Drake. Constructing concrete buildings.
1369 F. C. Hills. Manufacture of gas.
1402 J. M'Kean and J. Stenhouse. Preparation of materials for sizing yarns.
1405 J. H. Johnson. Preserving meat. (A communication.)
1434 H. A. Bonneville. Measuring the flow of liquids. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the lis of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 15, 1868.

3255 R. W. Pearse
3257 J. M. Napier
3265 E. T. Hughes
3266 W., J., and J. Busfield
3270 G. Fitt
3272 T. Wood
3279 A. Barclay
3282 W. H. Richardson
3290 W. Brewster
3323 W. Mort
3378 J. M. Napier
3428 R. Porter
299 R. J. Moser
332 J. Thompson

Sealed May 19, 1868.

3281 C. Mole
3284 H. H. Lloyd
3286 J. Oppenheimer
3287 H. Greene
3288 Baroness C. de Lavenant
3291 L. B. Joseph
3293 W. R. Lake
3295 J. Townsend
3299 W. R. Green and J. G. Freeman
3300 W. Blundell
3311 A. Munro
3312 G. Welch
3314 G. D. Hughes
3318 P. Salmon
3320 W. Macnab
3332 R. Ward
3342 C. E. Penny
3343 J. A. and J. Hopkinson
3348 C. T. Higginbotham
3357 A. M. Clark
3379 E. Wood
3380 J. R. Pratt
3392 W. C. Houghton
3396 A. M. Clark
3402 W. Starkey
3489 W. Clissold

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

1322 W. Chubb and S. Fry
1341 W. Deakin and J. B. Johnson
1357 R. Leddicoat
1371 W. Manwaring
1387 A. V. Newton
1392 W. E. Newton
1449 G. Elliot and R. P. Clark
1665 W. Clark

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

1225 J. and J. Bullough
1226 G. S. Goodall
1253 D. K. Clark
1261 A. Allan
1275 J. Hughes
1295 T. Aveling and H. Rawlinson

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department), on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennett Woodcroft, Great Seal Patent Office, 25, Southampton-buildings, Chancery-lane.

WOOD BROTHERS'
PATENT OBLIQUE TRANSVERSE TUBES
For the Flues of Cornish Steam Boilers.

THESE Tubes are exceedingly simple in construction and application, and very durable. They give a greater amount of heating surface than any other transverse tube that can be put in a flue of the same piameter, consequently will generate more steam with greater economy of fuel, and they can be repaired or replaced much more readily than any others.

As these Tubes are put in obliquely, and at a proper inclination, having the flanches at both ends inside the flue, they may be put in or taken out of their places through the flue without passing inside the boiler at all, thus giving the opportunity of applying them to boilers already in use without disturbing them or taking out the flues, whatever be the relative dimensions of the shell and flue.

FOR PRICES, AND A LITHOGRAPH OF THE BOILERS, APPLY TO

WOOD BROTHERS, DON BOILER WORKS, SHEFFIELD. B 1

PARIS EXHIBITION, 1867.—GOLD MEDAL.

CLAYTON, SHUTTLEWORTH & CO.,

At the Great Triennial Trials of the ROYAL AGRICULTURAL SOCIETY of ENGLAND, held at Bury St. Edmunds, July, 1867, received the following Awards:—

For Single Cylinder Portable Steam Engine, THE FIRST PRIZE OF £25.
For Double Cylinder Portable Steam Engine, THE FIRST PRIZE OF £25.
For Horizontal Cylinder Fixed Engine, THE FIRST PRIZE OF £20.
For Double Blast Finishing Thrashing Machine, THE PRIZE OF £15.
Also the Society's Silver Medal for Adjusting Blocks for Machines.

The duty performed by all C., S., and Co's Engines on this occasion considerably exceeded that of any others. C., S., and Co. refer with pleasure to the fact that the duty of their "Commercial," or Single Valve Engine, at Chester, so long ago as 1858, was not equalled b any "ordinary" Engine at Bury.

CLAYTON, SHUTTLEWORTH & Co.,
LINCOLN, and 78, LOMBARD STREET, LONDON. B 29

THE "LOTHIAN" CANNEL COALS.—These Cannels are extensively used in the gas works of Edinburgh, where the illuminating power of the gas is the highest in Britain.
The yield per ton is 12,573 cubic feet, illuminating power 33·8 standard candles; coke per ton 1,016lb.
Ports of Shipment, in the Firth of Forth.
For prices, and other information, apply to Mr. John Romans, C.E., 53, Frederick-street, Edinburgh. B 58

TO MERCHANTS, MANUFACTURERS, IRONMONGERS &c.

THE SHEFFIELD STANDARD LIST (ILLUSTRATED). Seventh dition, enlarged and improved.
Containing about 2,000 accurately engraved Patterns and the Prices of Files, Rasps, Saws, Joiners' Tools, Light and Heavy Edge Tools, Lancashire Tools, Lathes, and other Machinery; Machinists, Engineers, Platelayers, Plumbers, Turners', Tinmen's, Engravers, and Coopers' Tools; Spades, Shears, Skates, Anvils, Bellows, Springs, Wire, and other Sheffield Goods.
The patterns are drawn under the supervision of the most eminent makers, and the work comprises many patterns and prices never before published.
Price, complete, 10s.; post free, 11s. A cheap unabridged edition, post free, for 6s. 6d.; also an edition on thin Bank Paper, for foreign postage, 7s. 6d.; post free, 8s.
Sold only by the Engravers and Publishers, BARRAS and Co., Sheffield. A 48

PATENTED IN ENGLAND, FRANCE, &c., &c.

THE NEEDLE LUBRICATOR
(LIEUVAIN'S PATENT).
Samples 1s. 3d. each. 15s. per dozen.
This invention saves 75 per cent. in oil.
It is generally adopted for shafting, &c.
It supersedes all others at any price.
Its action is simple, effective, and complete.
Sole Consignees,
CLARKE AND DUNHAM.
PATENTEES OF THE MILLSTONE BALANCE.
48, MARK LANE, LONDON. B 42

MOULTON'S PATENT EMBEDDED STEEL AND INDIA-RUBBER SPRINGS for Railway Carriages, Locomotive Engines, Buffers, &c., possess greatly-increased power, as compared with the ordinary India-rubber Springs; are more uniform in their action, counteract the compressibility of India-rubber alone, and are not liable to break from sudden concussion, or the inequalities of the permanent way.
Prices and further particulars may be had on application to the Patentees, S. MOULTON & CO., Manufacturers of India-rubber Springs, Steam Packing, Washers, Hose, Tubing, Machine Belting, Garments, Blankets, Sheeting, Elastic Hot Water Beds, Cushions, &c., &c.
Kingston India-rubber Mills, Bradford, Wilts. A 34

WROUGHT IRON TANKS, CISTERNS
GIRDERS, FUNNELS, &c., Plain or Galvanized.
Cattle Troughs, Iron Cart Bodies, &c.
GALVANIZED OR LEAD SERVICE PIPE, BRASS BALL VALVES, ETC.
Merchants and Shippers Supplied.
HENRY WATSON & Co.,
60, VAUXHALL STREET, LAMBETH, LONDON. A 20

THE NEW OIL TESTER
Is the only one that Indicates the Cash Value of Lubricating Oil. See Testimonials.
J. BAILEY & CO., Sole Licencees,
ALBION BRASS WORKS,
SALFORD, LANCASHIRE. B 59

NEILSON'S LATHES
ARE THE CHEAPEST AND BEST.
With Planed Iron Beds, Standards, Turned Flywheel, Hand Rest, Chucks, Crank, Treadle, &c., complete, 3in., 4in., 5in., and 6in. centres. Illustrated Lists, two stamps.
T. and R. NEILSON, ENGINEERS, &c.,
27, NORTHAMPTON-SQUARE, E.C., AND 232, STRAND.
N.B.—Amateurs supplied with Lathe Castings, Materials and Instructions for fitting up. B 60

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, MAY 29, 1868.

THE NAVY ESTIMATES.

THE vast importance of this subject is a sufficient reason for our again calling the attention of our readers to what the Admiralty propose to do during the present year. In January last, we expressed a hope that double the sum would this year be appropriated to the construction of ironclad ships than was last year devoted to that purpose. Our hopes have not been fully realized, although a considerable stride has been taken in the direction we indicated. Mr. Corry stated in his speech that "it was the unanimous opinion of his colleagues and himself, that as large an amount as could possibly be spared from the other departments of the naval service, having due regard to their efficiency, ought to be appropriated to the construction of armour-plated ships." It is well known that this determination was not the view of the Admiralty when the Navy Estimates were first framed. On the contrary, it was the speech of Mr. Gregory, President of the Institution of Civil Engineers, that goaded the Admiralty to save on other votes and spend on ironclads. Mr. Gregory stated that less than one-twelfth of last year's money was so spent, and urged a great change in this respect this year, and he was unanimously supported by the press of the country. This is why more is to be expended this year in really strengthening our navy, and there is no other reason.

With reference to Mr. Corry's remarks about the "Inconstant" and "Volage," he seems still to take credit for building a second "Volage," in preference to a second "Inconstant," owing, no doubt, to the fact that the "Volage" is only half the tonnage of the "Inconstant." But the recent highly-successful trials of the American "Wamponoag"—a ship very much larger than the "Volage," and not very far short of the "Inconstant" in point of size—must have raised in the minds of many persons very grave doubts as to the wisdom of the change. We do not wish to say one word against the "Volage" and "Active"; they are, no doubt, exceedingly promising vessels, and will attain a very high speed for their tonnage. But the great object of these vessels unquestionably was to surpass, both in speed and in armament, the long American unarmoured ships, of which the "Wamponoag" is a specimen, and we have not the slightest hesitation in predicting that, while the "Inconstant" class will accomplish this object, the "Volage" will not. There is no comparison between the armament of the two ships, and no one who knows how much easier it is to get speed with a large ship than with a small one can doubt that the speed of the "Volage" will fall greatly short of the "Inconstant." It will probably be a year hence before either ship is tried, but when the trials have taken place we shall expect to find that this feature of Mr. Corry's management has given but little satisfaction. The difference between the "Druid" and "Briton" and the "Blanche" class is so small—consisting only of the addition of a few feet of length to enable a few more guns to be carried—that it is unnecessary to dwell upon it. It may be worthy of remark, however, that the estimates and policy of the Government point clearly to the fact that the "Druid" will be the last war ship built at Deptford. If the Government had intended to continue building there, the present year's programme must have been extended, for no provision is made in the Estimates for laying down any further vessels.

Much criticism has taken place respecting the design of the "Invincible" class, and whatever may be the merits or defects of that design, they will be mostly repeated in the "Iron Duke." It will not be too ungracious, perhaps, if we say that it is not at all impossible that the opposition to the "Invincible" class is largely due to the fact that the all-round fire of its upper deck battery has excited the jealousy of the turret advocates, for it cannot be denied that the "Invincible" will, and the "Captain" will not, have at least one heavy gun raised high above the sea, and protected by armour, capable of being directed to every point of the horizon. It would appear from the description given by Mr. Corry that the "Swiftsure" and "Triumph" are intended for a somewhat different service to that for which the "Inconstant" class is designed, since, while resembling them in their general dimensions, their armour, and their armament, they differ from them in having single lifting screws, and also in having their iron bottoms sheathed with wood and copper. These two facts taken together would seem to point to the use of the "Swiftsure" and "Triumph" for distant foreign service, while the "Invincible," "Audacious," "Vanguard," and "Iron Duke" (which are all exactly alike) are no doubt more particularly intended for European service. The question may nevertheless be raised whether it would not have been better to give the whole of these ships the advantages of a clean bottom and a lifting screw; and we are the more disposed to raise this question seeing that the whole of the six ships have been, as we have taken pains to ascertain, furnished with a spread of canvas unusually large for ironclad ships. A great misapprehension prevails respecting the upper deck battery of these six ships. It is commonly represented as overhanging the full breadth of the ship, like a paddle-steamer's sponson, and, consequently, the guns are said to be far removed from the centre of the ship, and subject to enormous motion when the ship is rolling. Now, neither of these representations is correct. The battery undoubtedly projects beyond the upper deck, but then the side of the ship is curved inwards to such an extent (as in the old French "Canopus" line-of-battle ship, and in Admiral Paris's designs), that in point of fact the very outside of armour of the battery is within the breadth of the ship at the waterline; and, as the ports are in the inclined 'thwartship bulkheads, the port pivots, and therefore the guns, are actually much nearer the middle line of the ship than they would have been had the side gone up straight, or with an easy curve, in the usual manner. These guns will therefore be practially steadier in a sea-way than the upper deck guns of an ordinary ironclad.

The "Sultan" is obviously another "Hercules," but with this difference, that her right aft fire is to be obtained from the upper deck by means of a projecting battery very much like that just described for the "Invincible" class. The only other important ships proposed to be built this year are the "Glatton" monitor and the ram "Hotspur," both of which are of novel construction, and will therefore be dealt with in a future article. Meantime, we have seen sufficient to show, first, that the naval policy of the Government has been materially modified by public opinion; and, secondly, that the development of that policy will still require to be carefully watched by ourselves, and other organs of similar views.

ALLOYS AND QUASI ALLOYS.

WE have noticed from time to time various mixtures or alloys of metals which have been brought forward as likely to be useful in manufacture. Some of them no doubt true alloys, but most of them simple mechanical mixtures. There seems to be a good deal of confusion in the notions of most people as to what is an alloy and what is not. To many a simple mixture of metals is an alloy, whether there be any chemical combination or not, or rather whether there be a perfect chemical combination or not. Any two metals that will enter into combination when melted together will certainly unite to a certain extent whether they be melted together in proper proportions or not. But then, if one of the constituents predominate over the other, the excess will remain in a free state. We noticed two of these so-called alloys of lead and tin lately, where the mixture had to be continually stirred till it was cool to prevent the precipitation of the free lead on account of its greater specific gravity. No doubt these were alloys to a certain extent, and in both of the mixtures the alloys may or may not be the same, according to circumstances, tin being capable of uniting with some other metals in four different proportions, but only in two with lead.

It is surprising how few really valuable alloys we possess; one may count nearly all of them on the fingers, so few alloys are malleable. For castings many others can be used, but they must be true alloys, otherwise the free metal will tend to separate itself from the other portion of the mixture and so spoil the casting; we have seen this result frequently, and especially with lead and zinc. Tin is a metal which will alloy with almost every other metal, and would indeed be a valuable constituent of various alloys if it were not for the property it has of making nearly all the compounds it enters into crystalline—consequently brittle. The only exception that we at the present can call to mind, are the alloys of tin and lead. We do not consider gun metal a true alloy of copper and tin, but simply an alloy of tin and copper in an excess of copper; but this is the most valuable quasi alloy we possess. The normal alloy of copper and tin is very brittle, the proportions of each are nearly equal, the copper being a little in excess of the tin, tin being tetratomic and copper biatomic. When electro-plating was discovered, brass and copper were the principal metals used as the bases of the articles which were manufactured to be plated, these being in use for the old close plating process.

But a new basis was desired more nearly the colour of silver with which the articles were to be covered. Naturally, attention was directed to the alloy called German silver, which already existed, but was not much known or used. This is a triple alloy of zinc, copper, and nickel, and the proportions for the best qualities are 50 copper, 30 zinc, and 20 nickel. For a true alloy, if nickel be biatomic, the proportions 50 copper, 26 zinc, and 24 nickel would be nearer the true equivalent ratios. But if nickel be tetratomic, as it is now believed by some, the proportions will be 34 copper, 35 zinc, and 31 nickel. Very little German silver in commerce is really a true alloy, and most of it contains but a small proportion of nickel; in fact, much of the metal going by that name is little better than highly speltered brass. The reason of this is that nickel is comparatively a dear metal, the pure being 6s. or 7s. a pound and the crude 3s. or 4s.; so that an alloy using even the crude metal cannot be produced under 2s. 6d. a pound, if nickel be biatomic: but what is called good German silver can be bought for 1s. 5d. a pound. For electro-deposit the true alloy is much superior to the metal found in commerce, a sound deposit is much more easily obtained upon it, and it is much more easily cleaned; but labour is cheaper than nickel.

Many fancy names have been given to this alloy, such as nickel silver, electra, &c. There can be no doubt that true alloys are real chemical combinations, for the alloy of two metals seldom exhibit the properties of the two metals composing it, but have dis-

Digitized by Google

tinctly new properties. Alloys may be harder than either of the metals composing it, and may be denser than the mean of the densities of the two metals; moreover, its melting point may be higher or lower than either of them. Much has been done in finding out good alloys for various manufacturing purposes, but it has been done by mere blind groping; but let an alloy be considered to be a chemical compound, then it will be possible to see theoretically what combinations may or may not be attempted with any likehood of producing a true alloy. Not that its properties can be predetermined, but, whatever these properties may be, it will be known that they will be constant, which is not the case with our present alloys; scarcely two meltings have precisely the same colour or hardness, or, in fact, any of their properties.

CONVERSAZIONE OF THE INSTITUTE OF CIVIL ENGINEERS.

IF any doubt were entertained of the inadequacy of the Institution building in Great George-street to meet the demands upon it for space, it would have been put to flight on Tuesday evening, at the conversazione given by the President, Charles Hutton Gregory, Esq. The rooms and theatre of the Institute were thronged from first to last with a distinguished company, the attendance being more numerous than ever, and, so far, the gathering was a great success. But the wedge and crush was occasionally uncomfortably inconvenient, notwithstanding that Mr. Forrest had done his best to arrange the models, &c., so as to occupy the least possible room. And this led to another practical evil; the models and apparatus were crowded into each other, and, in some cases, were entirely hidden from view. For example, an interesting collection of iron and steel samples, which had undergone testing by Mr. Kirkaldy, who sent them for exhibition, were obliged to be placed under a table. Many other drawbacks there were of a similar character, which the executive are powerless to deal with; indeed, the wonder is, that, considering the want of space, they managed so well as they did. And not only to such exceptional evenings as last Tuesday do these remarks apply, for often on the ordinary meeting nights is the lecture theatre inconveniently filled. However, we congratulate the Institute on the circumstance of these crowdings; they show a healthy and expanding condition. We also congratulate the members upon the fact that arrangements have been made to enlarge the theatre to about double its present area, and, we believe, the opening meeting of the next session will take place in the enlarged hall.

We have said that Mr. Gregory had a brilliant reception. In proof of this we append a few names from the eight hundred and odd gentlemen who honoured the president's invitation. Of course, all the leading members of the profession were there, and amongst the visitors we noticed Professor Abel, Captain Arron, General Balfour, Admiral Sir E. Belcher, Dr. Billing, Mr. E. Bowring, C.B., Captain Burstal, Mr. P. H. Calderon, R.A., Colonel Campbell, R.A., Mr. E. Chadwick, C.B., Lord Alfred Spencer Churchill, Admiral Collinson, Mr. S. Cousins, R.A., Mr. E. W. Cooke, R.A., General Millans del Bose, Professor Donaldson, General Dunn, Mr. W. P. Frith, R.A., Mr. Glaisher. Dr. Granville, Earl Grey, Sir George Grey, Bart., M.P., General Hay, Lord Headley, Major Honchen, B.S.C., Field-Marshal Lieutenant Baron Jochmins, Mr. E. K. Karslake, M.P., Mr. Commissioner Kerr, Mr. Charles Landseer, R.A., Sir Charles Lanyon, M.P., Bishop of Limerick, Sir Arthur Mackworth, Bart., Alderman Sir F. G. Moon, Bart., Professor Partridge, Dr. Percy, Mr. H. W. Phillips, Dr. Quain, Lord Redesdale, Mr. Samuda, M.P., Mr. Warington Smyth, Mr. Lumb Stocks, A.R.A., Sir Henry Thompson, General Tremenheere, Mr. C. V. Walker, General Geddes Walker, Sir Thomas Watson, Bart., Mr. Westmacott, R.A., Lord Justice Page Wood, Mr. Basil T. Wood, M.P., Mr. Wyon, &c., &c.

Turning from the company to the objects of art and science exhibited, we will first notice the patent hydrostatic sluice gate, invented by Mr. W. Edwards, C.E., Mysore, P.W.D., and exhibited by Messrs. Turner, of the St. Peter's Ironworks, Ipswich. This apparatus consists of a gate made in wrought or cast iron, having a ram or plunger attached to each end of the upper cross piece, working in upright cylinders, the forcing of water into which, by means of a small force pump raising the gate, which shuts against a frame, composed of two uprights attached to the cylinders, and a sill upon which they stand. It is kept in position when up by a pair of vertical guides, mounted on the heads of the cylinders. Two graduated scales made in brass are fixed to the guides, divided into feet, and 100 parts of a foot; a vernier attached to the gate points to one scale, showing the lift of the gate in feet and decimals; the other scale is read by a vernier attached to a float, thus indicating the depth of the water-head with the same accuracy. The quantity of water, in cubic feet, discharged per minute by the sluice may—with the aid of hydraulic tables—thus be correctly ascertained. The working model showed the apparatus to be simple in construction, the gate itself being the only moving part except the pump, and thus not liable to be out of repair. The pump is placed in an iron box, which may also contain the regulating cocks, for adjusting the rise and fall of the gate, these being kept under lock and key. The supply can only be regulated by the officer in charge, who would have possession of the key.

Close by this sluice gate was Mr. Latimer Clark's pneumatic apparatus for signalling in trains, the tubes of which were laid completely round the hall. Mr. Clark's principle of pneumatic communication is very simple. A pair of circular bellows, or, for greater durability, a pump, is placed under the tender of the engine, the piston of which is kept working slowly as long as the train is in motion, being actuated by a crank and pulley, with a strap working round the axle of one of the wheels. This pump has ordinary india-rubber valves, and is connected to an exhaust tube, about the size of the finger, which runs beneath the carriages the whole length of the train, its extreme end in the hinder guard's van being closed by a plug; the pump exhausts the air from this tube (as long as there is any air in it), and at every stroke forces it out through a whistle which is fixed on some part of the engine or tender near the ear of the driver. A tap is provided in each of the guards' vans by which they can at will admit air into the pipe and cause the whistle to sound; and a modified form of the same arrangement is provided in every carriage; this constitutes the whole apparatus. When the train starts, the pump at first causes the whistle to sound, but after a few strokes the pump soon exhausts all the air from the closed tube, and although it continues to work, it cannot eject any more air, and can no longer blow the whistle, which necessarily, therefore, remains silent throughout the rest of the journey. But at any moment, while the train is in motion, if one of the guards wishes to call the driver's attention, he has only to open the tap which communicates with the exhaust tube beneath his van, and the air being thereby admitted, the whistle on the engine will begin to sound violently, and will continue to do so until the driver's attention has been obtained. The guards may also, if necessary, give special signals to the engine driver by opening their tap once, twice, or thrice.

Passengers may also make a communication to the driver; but the arrangement is such, that having once opened the communication they cannot close it again, and the whistle will continue to sound until the train stops, the driver acting as circumstances seem to require, and slackening speed, or stopping at once, or at some neighbouring station, at his discretion. In the event of a signal being made by the passengers without any obvious reason, he would probably signal to the guard by his steam-whistle, so that all parties might remain on the *qui vive* until their arrival at the next station, where a glance along the train at once discloses the carriage from which the signal proceeded. The accidental separation of a portion of a train, and especially of a heavy goods train, is a not unfrequent accident, and it sometimes happens that the driver proceeds a considerable distance before he discovers the separation. There is much loss of time, and some danger, in backing to seek the hinder portion of the train, especially if the accident occur in a tunnel or on a dark night, as the detached portion, although showing no visible light, may continue in motion for a long time before the guard becomes aware of the separation. All risk from this cause is obviated by the use of these signals; for if any portion of the train becomes separated, the whistle gives instant alarm, and the driver has time to warn the guard by his steam-whistle before any danger can ensue. Those of our readers who wish to go into the details of Mr. Clark's apparatus will find it fully described and illustrated in the MECHANICS' MAGAZINE for January 17 last. We may add that this system is now in operation on the London, Chatham, and Dover Railway.

Amongst the objects of telegraphic interest we noticed a well mounted selection of submarine cables, now being manufactured at the India-rubber Company's Works, at Silvertown. Amongst them were the three varieties of the present Cuba cable, shortly to be submerged between Havana and Key West. The main cable weighs three tons and the shore end about twenty tons per mile. All of them were well protected with Clark's bituminous compound. There were also specimens of cables now being manufactured for the Electric and International Telegraph Company, to be laid in the North Sea. The main cable weighs about ten tons and the shore end about twenty tons per mile; both are covered with hemp protected by bituminous compound, and are splendid specimens of heavy shallow water cables. This cable consists of four conductors, and the insulation of this, as well as of the Cuban, is higher than previous cables. These specimens were exhibited by Mr. G. E. Preece, who also showed some varieties of the new American insulator—Brooke's paraffin—now so much used. Electricity was well represented by Mr. Apps and Mr. Ladd, the former of whom exhibited his inductorium, which attracted much attention from the thickness and extreme rapidity of the discharges. Mr. Ladd showed his dynamo-magneto machine, which was also a centre of attraction for electricians. Dr. Guthrie sent his voltastat and voltameter, which is an instrument for regulating and measuring the force of a galvanic current. This ingenious apparatus will be fully described and illustrated in our next.

Mr. Laidlaw exhibited his patent pump or exhaust, which is small and compactly arranged. It has two rotary cylinders, and there is an entire absence of any leather, so that no damage arises from pumping water containing gritty substances. The small pump we saw was capable of pumping from 1,500 to 1,800 gallons per hour to any required height, and of draining from a depth of from 15ft. to 20ft. There were several steam pumps and donkey pumps by various

Digitized by Google

makers, and amongst others that of Mr. Waygood, which we describe and illustrate in detail on another page. There were also Messrs. Kittoe and Brotherhood's patent paragon steam pump for feeding boilers, &c., and a pump for the same purposes, by Mr. Davey, who also exhibited his isochronal governor, particulars of which will be found at page 144 of our issue for February 21 last. Messrs. S. Owens and Co. sent one of Mr. Bernay's centrifugal pumps, which are deservedly coming largely into use, and with which most of our readers are well acquainted through our columns. We, therefore, need only add that the construction of this pump is such that the revolving fan is entirely relieved from the pressure of the column of water on its outer surface. Hence we get a reduction of friction, wear and tear, and the absorption of less power. Mr. A. Jackson sent a compact arrangement of his gas furnace as applied to a very nicely-constructed one-horse power engine. This engine was at work all the evening, and, with the exception of the electrical apparatus, was the only machine in motion. It gave the company a good opportunity of judging of the value of this system, which is invaluable where an intermittent use of steam power is required, and, moreover, is now being largely applied where hitherto the use of steam power has been prohibited by the insurance companies. Mr. Mabson was present with one of his Belgravia sewing-machines, which is half-a-dozen sewing-machines in one, forming, as it does, every other machine stitch, and one of its own —an embroidery stitch—besides. Mr. Mabson showed some beautiful specimens of embroidered work produced by this machine, which we purpose illustrating in our next.

Mr. John Hughes, of the Millwall Iron Works, the well-known inventor of the stringer backing for armour plates, had a select collection of objects especially interesting to artillerists and military engineers. In the first place, there was a model of a wrought-iron shield made with tongue and grooved bar, designed to be placed in stone buttresses, as shown by Messrs. Lancaster and Hughes to the British Government in 1860, with the exception of the additional 5in. front plate, which is added to meet the increased power of modern artillery. Next, we observed a model of a wrought-iron shield, fixed on granite foundation, as proposed by Messrs. Lancaster and Hughes to the British Government in 1860, and which was subsequently adopted by the Russian Government in the defences of Cronstadt. Then there was a section of a wrought-iron caponniere constructed with tongue and grooved bars, with front armour-plates designed by Messrs. Lancaster and Hughes in 1862. No. 4 was a section cut from end of one of the rolled bars used in the Russian defences, and which was rolled at the Millwall Iron Works in 1864, the weight being 1,600lb. per yard run. The model No. 5 was that of a War Office shield with hollow stringer backing, designed in 1865 for conducting three series of experiments on one shield. The lower half is covered with a 9-inch plate, and the upper with a 6-inch plate; a part of this is then covered with three 1-inch plates on the laminated principle. We next come to a model of a bombproof wrought-iron shield with hollow stringer backing for fixing in earthworks, which was designed by Mr. Hughes for a foreign Government in 1865. Adjoining this was a model of a wrought-iron bombproof fort, with hollow stringer backing and armour-plated roof, designed by Mr. John Hughes for another foreign Government in 1867. No. 8 was a model of a segment of a wrought-iron circular fort with brick and concrete roof and hollow stringer backing, designed in 1867. There was also a full-size section of dovetail tongue and groove bars (similar to those used in the Russian defences), showing the mode of fastening back supports without "through" bolts; this is designed for a third-class defence. Another section similar to the last showed a mode of fastening on front armour plates with double dovetail hollow bolts; this was full size for third-class defence. Finally, there was a section of a hollow stringer for the backing of armour plates rolled at the Millwall Iron Works in 1865, weight 210lb. per yard.

Mr. Hughes also exhibited some of Mr. P. M. Parson's patent bolts for armour plates, the peculiarity of which lies in their shanks, which are hollow, but are of the same sectional area as the thread. Hence there is a saving of metal, besides which the elasticity of the bolt allows of a considerably greater amount of screwing up, without breaking it, than can be given to an ordinary bolt. There is also far less liability of the bolt to break through the thread, the sectional area being equal throughout. In November last year we witnessed some highly successful experiments with some of these bolts, particulars of which we placed before our readers at the time. We are glad now to add the results of some severe trials to which several armour-plate bolts have lately been subjected, and which have proved equally successful. First, a hollow bolt about 24in. long, and 3¼in. in diameter, hollowed nearly down to the screw thread, made of Millwall iron, was held up by the swelled head with the nut screwed on, and submitted to eleven blows from a monkey weighing one ton, and falling upon the nut from a height of 26ft. The bolt stretched 4½in. in a marked length of 13½in. = 33 per cent. of elongation before rupture. The second bolt was made from a special iron, and was 2ft. 6in. in length, and 3 in. in diameter. This bolt withstood sixteen blows from the same monkey, with the same fall, the result being an elongation of 6½in. in 19in., again equalling 33 per cent. of stretching, and thus bearing high testimony to the value of Mr. Parson's principle.

Marine engineering was mainly represented by some highly-finished models of engines bearing well-known names. Messrs. Maudslay, Son, and Field sent a beautiful model of the engines of the "Agincourt," of 1,350-horse power. From the same firm also came a model of the engines of Captain Phillimore's yacht "Hebe," of 40-horse power nominal. Messrs. Maudslay also sent an alarm whistle for superheated steam, which gives notice to the engineer in the event of the steam being too highly superheated. Messrs. Ravenhill, Hodgson, and Co. sent a model of the engines of the "Lord Clyde," 1,000 horse-power, 116-inch cylinders, and 4-feet stroke. Naval architecture had also its representatives. Messrs. J. and G. Rennie sent a model of the iron floating dock of Cartagena, in which the "Numancia" ironclad is now docked, as stated by us last week. This firm also sent a model of the Brazilian armour-clads "Colombo" and "Cabral," as used in the Paraguayan war. Sir W. G. Armstrong and Co. contributed a beautiful model of the little gunboat "Staunch" (illustrated by us on the 8th inst.), which was designed by Mr. G. W. Rendel, constructed by Messrs. C. Mitchell and Co., and engined by Messrs. R. Stephenson and Co., the gun machinery being by Sir W. G. Armstrong and Co. The London Engineering and Iron Shipbuilding Company sent a model of a design for an ironclad frigate of 5,282 tons and 1,100-horse power. The system advocated by Captain T. E. Symonds, R.N., was represented by a model of an armour-clad twin screw frigate on the end-on and broadside system, mounting twelve 300-pounder guns. Lastly, Messrs. Samuda Brothers sent a model of an iron screw armour-clad turret ship of 1,752 tons burthen and 600-horse power.

Were we even to make only an inventory of all the things exhibited, we should be unable to enumerate everything we saw on the present occasion. We must, therefore, content ourselves with a passing notice of a few more matters of interest before quitting the subject, to which, however, we shall return next week. A rock boring apparatus, contributed by Mr. Appleby, appears (from a block of hard grey granite, through which a large number of holes had been bored), to be worth more than a cursory notice, and we hope shortly to give a drawing and description of the machine, together with details of working. The cutter used is the diamond crown, which was patented by M. Leschot, and has been purchased by Messrs. Appleby. The diamond crown rock borer, exhibited in work at the Paris Exhibition of 1867, differs, however, essentially from that under consideration, which, we believe, is the joint production of Captain Beaumont, R.E., and Mr. Appleby. We observed an ingenious hand signal lamp, by Messrs. Brown and Jones, which requires only one hand to change the colour of the light instead of both, as in the lamp now commonly used. Messrs. Moseley and Son had a collection of planes for various purposes, the chief novelty being a plane for preparing air-tight framing for show cases. Samples of this framing were shown, and certainly made a very good job. Mr. Rochussen exhibited some wire drawn from Berger's mild gun steel. To a piece of this wire, of very small diameter, was attached 280lb. of iron, which gave a load of 308,370lb. per square inch. This wire begins to elongate at 388,000lb. per square inch, and breaks at 427,000lb. Mr. H. K. York exhibited some beautiful specimens of raw and manufactured steel, made by his process. This consists in cutting up the pig iron in a red-hot state by means of revolving cutters, collecting the oxidized particles, and melting them in a crucible in the ordinary way. The samples of steel and the manufactured blades were of the highest character. Mr. W. Blundell sent a balanced-cone air and smoke escape of novel construction, based on sound principles, and of which we purpose giving details next week. The Manchester Boiler Association sent a model of a boiler which exploded at the Backworth Collieries, near Newcastle-on-Tyne, on January 13 last, and which was attended by several peculiarities shown in the model. Mr. W. Clark sent a working model of Batho's rivet-making machine, which swallowed up inch after inch of stout copper wire very rapidly, returning it in the shape of very neatly made rivets. Finally, there were some of Mr. L. Sterne's pneumatic rubber buffers, as now used upon the Great Western Railway, and of which, as also of the application of the principle to draw springs and buffers on the Metropolitan Railway, we shall have more to say hereafter. We cannot conclude without referring to the satisfactory character of all the arrangements, considering the want of room, and in congratulating Mr. Gregory upon the success of his conversazione.

TECHNICAL EDUCATION IN FRANCE.

THE report of the French Commission on Technical Instruction, appointed by Imperial decree, June 22, 1863, has been translated into English by M. Haussoullier, and presented by command of her Majesty to both Houses of Parliament. The report contains a large mass of valuable information, and many important recommendations, from which we infer that the French as well as ourselves are far behind the Germans in educational means, and appliances, and organization. The French Commissioners attach much importance to the ordinary apprenticeship system as a means of practical training, but report that it fails to satisfy the demands of technical instruction; and that the apprentices are often abused by over work, Sunday work, and exacting night work, and sometimes by bad food and ill-treatment. Much good is accomplished by

Digitized by Google

the societies for the patronage of young apprentices—such as the Society of St. Vincent-de-Paul, and the Societies of Orleans and Nantes—but these are inadequate fully to supplement the need, and other means of instruction are recommended to accompany the practical training of the workshop, upon which dependence must be mainly placed. The Commission recommend that the apprentices' time in the workshop should not exceed ten hours per day, and that they should have at least two hours of school instruction daily. In illustration of the very deficient means of instruction placed within the reach of apprentices and workmen in France, it is stated that the Empire, with 38,000,000 of inhabitants, has only two establishments for superior technical education, which do not supply for industry and for the scientific arms of the artillery and engineers instructional means for more than from 350 to 400 young men, whereas there are in Germany and Switzerland polytechnic institutes for every five and a-half millions of the inhabitants, and means for training above 4,000 pupils, counting only those regularly matriculated and obliged to attend the classes. At Vienna the institute has 900 pupils; that of Prague, 718; of Carlsruhe, 589; of Berlin, 350; and so on. In Germany and Switzerland the total school fees range from 100f. to 150f.; and in many places for 1,000f. per annum, or even less, proper board and lodging can be obtained. The cost of similar instruction in Paris is about 3,000f. per annum. We fear that it may be added with truth that a course of instruction similar to that given in these continental polytechnic institutes is not to be had in England at any price whatever.

ENGINEERING FIELD WORK.*

THE simplest and most elementary form of surveying is that which is accomplished by the aid of the chain alone, together with a tape and offset rod, and might with strict propriety be termed measuring, since the object is to ascertain the relative distances apart of the various physical features of the locality. In the first four chapters of the book under notice, full and accurate instructions are given, not merely respecting the different operations necessary in what is called "field work," but also regarding the equally important item of "office work." It must always be borne in mind that no matter how accurately the field work may be performed, it is all vitiated by bad, careless, and incorrect plotting. It is of little use making notes with precision if their results be not transferred to the drawing paper with corresponding exactitude. We cordially endorse the opinion of the author on this point, and maintain with him that attention to what may at first appear very trifling details, in reality ensure the accuracy and fidelity of the work. The student and professional pupil will not fail to observe that it becomes necessary to employ several problems in plane geometry for the purpose of overcoming many minor difficulties in engineering surveying. These problems are explained in full, although at the same time we would advise all those who intend joining the ranks of the profession to obtain previously to their commencing their professional studies a good sound knowledge of the rudiments of plane geometry, and, if possible, of plane trigonometry also.

It has been frequently remarked that very good work may be done with very bad instruments, and to some extent the remark is true. There is, however, one point to be taken into account in this case, and that is that the person using the imperfect instrument is aware of its defects. If he knows it to be out of adjustment, although he may not be competent to put it in adjustment himself, yet he is well able to make allowances for its shortcomings, and, by many devices known to the experienced hand, counteract the errors he would otherwise be led into. Mr. Haskoll describes fully the usual instruments in vogue with the profession, and gives the preference to the theodolite, as it justly deserves. In fact, it may be stated that any engineer who possesses a first class 6in. theodolite, and knows how to use it, can never be mastered in any difficulty that may arise with respect to ranging or setting curves, bridges, or other work that may fall to his duty. Three chapters on hydraulics, and harbour surveying, and deep sea soundings bring to a close that portion of the volume devoted to surveying. In the latter portion of the book, several chapters are devoted to the subject of levelling, a branch of study and practice if possible more important than that already treated of. It is not very difficult to discover an error in surveying, particularly if one is acquainted with the locality, and the error be rather a large one, but the case is very different with levelling. An error in the levels can scarcely be discovered unless the ground is actually levelled over again, and frequently parliamentary plans have been rejected in committee from an error or inconsistency in their levels. In addition to the ordinary description of spirit levels, the author describes the mountain barometer and the manner of using it. This latter instrument is indispensable in determining trial lines in mountainous countries, when the usual means could not be applied until some kind of a path or standing place were made. Numerous plates and diagrams attached to the volume serve to render that indispensable aid to the text which the clearest written treatise invariably requires.

* "The Practice of Engineering Field Work Applied to Land, and Hydraulic, Hydrographic, and Submarine Surveying and Levelling for Railways, Canals, Irrigations, Roads, Towns' Water Supply, Rivers, Docks and Harbours, and Deep Sea Soundings; the Use of Surveying and Levelling Instruments, of Barometers and Thermometers for Exploring Levels: a Complete Treatise on Setting Out Curves." Second edition, revised, with considerable additions. By A. DAVIS HASKOLL, Civil Engineer, late Resident Engineer of the Great Western and Brentford Railway and Dock, and of the Ottoman, Smyrna, and Aidin Railway; author of "Railway Construction," &c. Vol 1: London: Atchley and Co., 106, Great Russell-street, Bedford-square.

ELECTRICITY AND TELEGRAPHY.

WE are glad to be able to announce the restoration of communication through the Persian Gulf cable. This took place on the 23rd inst.

The bill for acquiring the electric telegraphs has again been postponed, and it is now fixed for the second reading at a morning sitting on June 6.

The submarine cable between Malta and Sicily was lately interrupted. The fault was found near Modica, on the Sicilian side; the cable fortunately was speedily repaired, so that the delay to communication was but slight.

We regret to announce that the cable from France to Jersey is interrupted. We may shortly hope to hear of its being repaired, as the present season of the year allows the necessary operations to be performed with greater expedition.

A trial of telegraphic speed has lately taken place in America, on the wires of the Western Union Telegraph Company, from Washington to Cape Breton. Ninety-four messages of twenty words each were transmitted by one wire in an hour. On the same day, thirty-three messages were sent in the same number of minutes from Cape Breton to New Orleans.

The cable for Key West and Havana has just been completed at the Silvertown Works, and is being shipped on board the "Narva," now lying in the river off the works. In our next, we shall give a full description of this cable, which, for electrical perfection, surpasses any other similar cable hitherto manufactured.

The prospectus has been issued of the Anglo-Mediterranean Telegraph Company, who propose providing a direct and thoroughly efficient line of telegraph to Egypt. As the first step towards this object, they have contracted with the Telegraph Construction and Maintenance Company to purchase their overland line, now in course of construction, and nearly completed, between Susa, in Italy (the terminus of the French lines), and Modica, in Sicily, where the line will be joined to the Sicily and Malta cable. This land line is 1,300 miles in length, and has been constructed under a concession for forty years. It will be handed over in perfect working order, and worked throughout by the English staff of the company.

It is proposed to abandon the present communication by the coast line between Malta and Alexandria, now leased by the Telegraph Construction Company from the Government, who have "promised, in consideration of an annual payment of £2,000 for a term of fourteen years" to abandon it. In order to complete the communication with Alexandria, a new deep-sea cable 900 miles in length is to be manufactured, and laid direct from Malta. A contract for this cable has been entered into with the Telegraph Construction Company, which "provides for the making, laying, and delivery to the company, in perfect working order, within four months, of a deep-sea cable capable of transmitting messages at a speed equal to the existing Atlantic cables, and having an external covering suited to the known requirements of the Mediterranean bed." At Alexandria, the cable will be connected with the existing land lines to Cairo and Suez. "The sum to be paid for the making and laying of the deep-sea cable, for the purchase of the land lines through Italy, and the present interests in the existing Malta-Alexandria line, is £245,000." The projected cable will form one of the links in the chain of submarine telegraph communication to India and the East. We believe the money is all subscribed, and we may, therefore, expect to see the cable shortly commenced; and before the summer is over, we trust this line will be completed, so that we may not be entirely dependent on the present line, which of late has been so much out of order.

In our review of the past year, we alluded with great hopes to the coming year as being likely to see several schemes brought out, showing that confidence was restored and progress in telegraphy was once more the case. We are glad to find our prognostications fulfilled, for activity is being shown now, particularly in submarine telegraphy. In addition to what we have lately mentioned, there is this Malta and Alexandria cable, a length of 900 miles. The India Government are going to lay an alternative length of 500 miles in the Persian Gulf. This length is intended to be laid from the existing station at Gradur, along the Persian shore, past Mussendun, to Faiz on the Mekran coast, where it will join the land lines to Kurrachee. Interruptions have usually taken place between Kurrachee and Gwadur, so that when this cable is laid we may then expect to have always one line of communication open. It is not yet decided whether the conductor of the cable will be insulated with gutta-percha or Hooper's material.

The cable about to be laid from the north-east coast of England to Denmark, of about 300 miles, is being insulated by Hooper's material, at his works at Mitcham; the insulation is something marvellous. The cable itself is being manufactured by Messrs. Newall and Co. A further length of cable of about 250 miles will, ere long, be manufactured for the Black Sea, in connection with the Indo-European Telegraph Company. Mr. Henley is manufacturing a length of about forty miles for the Norwegian Government, and some shorter lengths for other parties. At the Silvertown Works the India-rubber Company are making over thirty miles of ponderous cable for the Electric and International Telegraph Company, and have just completed 105 miles for the Cuba cable. These lengths give a total of nearly 2,200 miles, a result highly satisfactory, as it will give plenty of employment to the various submarine factories, which, unfortunately have not been very busy of late.

A Parliamentary paper has just appeared, containing Mr. Scudamore's reply to the pamphlet that lately appeared stating the case of the Electric and International Telegraph Company against the Government bill. In replying, Mr. Scudamore premises "that he is by no means certain that the pamphlet can fairly be regarded as an official statement of the company's case, or as proceeding from the chairman of the company, to whom it has, by some, been ascribed." The various statements and arguments in the pamphlet are reprinted by Mr. Scudamore, with his answers arranged in parallel columns, and we must acknowledge that Mr. Scudamore has, in almost every case, decidedly the best of it; his arguments tend to support the complaints of the various

Digitized by Google

chambers of commerce that "the existing charges for the transmission of messages are too high, that under the existing system there is often delay in the transmission of messages, that many important districts are unprovided with facilities for telegraphic communication." He again brings forward figures and statements in support of his original argument, that, as in Belgium and Switzerland, the development of telegraphic correspondence has been greatly stimulated by the annexation of the telegraphs to the post-offices of those countries, so in this country like results would follow the adoption of similar means, and "that from the annexation of the English telegraphs to the English Post-Office there would accrue great advantage to the public, and ultimately a large revenue to the State." There are too many points in this reply for us to take notice of, but all the statements and arguments are satisfactorily replied to, and fresh proofs given of the feasibility and advantage of the Government scheme. Although many petitions have been presented to Parliament from various shareholders of the companies against the scheme, yet, since the "bill was published, thirty chambers of commerce, and other public bodies, have petitioned in its favour."

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

NEW USES OF ELECTRO-MAGNETISM—ALARUM FOR MODERATOR LAMPS—NAPHTHALINE COLOURS—HAIR CUTTING BY MACHINERY.

THERE are many who look forward to a time when electro-magnetism will supersede steam as a motive power. It is quite possible that electricity may be employed as a motive force, but the amount of mechanical work which it is capable of doing is comparatively small, and it must be enormously expensive. There are circumstances, however, in which cost is a matter of small consideration, and in these electricity may sometimes be turned to useful account. A lady may wish for a sewing machine, but the labour of driving it is more than she can exert. For such, M. Cazal has invented an electro-magnetic machine which we have no doubt will be competent to do the work with light fabrics. The details of this machine we must defer until a more complete account than we have yet met with comes to hand. For ornamentation, too, electricity is coming into use. You may see at a fashionable ball at Paris, a lady, on the top of whose head sits a butterfly or a humming bird. The fly and the bird flutter their wings in the most natural way possible. How is it managed? Why, within the chignon are concealed a small battery and a minute Rhumkorff coil. On the bosom of another may be a brooch, with a head upon it, the eyes of which turn in all directions. This, too, is accomplished by the use of a battery and coil so minute as to be concealed within the brooch itself. These, and more useful things, small batteries for curative purposes, easily carried about the person, are the inventions of M. Trouvé. The batteries of zinc excited by solution of sulphate of mercury, are enclosed in vulcanite cells, so that the exciting solution cannot escape to the damage of the wearer.

There is another French invention that deserves a line. It is a contrivance by which a warning is given that a moderator lamp wants winding up. As the rackwork descends, it causes a small hammer to fall on a bell fixed to the side of the work. The means by which this is accomplished will be readily imagined by any mechanic.

Naphthaline colours, it is anticipated, may some day compete with, if not eclipse, those from aniline. The body has been recently studied by M. Vohl, who gives instructions for the preparation of naphthyl-carmin, and some other useful derivatives of naphthaline. We give the proportions as we find them, with the remark that here, as in most such cases, the experimenter will probably have to decide on the best for himself. M. Vohl first dissolves twelve parts of naphthaline in 109 parts of strong sulphuric acid, and then adds by degrees 89 per cent. of bichromate of potash. When the reaction which ensues has ended, boiling water is added, whereupon some carbonic acid is disengaged. Carbonate of soda is next added to neutralize the solution, and the whole is boiled for a quarter of an hour. It is now filtered, to separate the oxide of chromium. The filtered solution is now of a beautiful golden yellow colour, but the addition of hydrochloric or sulphuric acid causes an abundant precipitate of carmine red flocculi—the naphthyl-carmin. After this has been separated, the solution on evaporation will yield first the sulphate of potash, then chloride of sodium, and, lastly, phthalic acid, which only requires to be submitted to dry distillation with quicklime to yield pure benzol. Naphthyl-carmin, according to M. Vohl, is an acid giving, with alkalies, a golden yellow solution, which dyes silk and wool, without mordants, either orange or violet.

Hair cutting by machinery is now an accomplished fact, so far as horses and oxen are concerned, and it seems to us by no means impossible in the case of the human head. M. Nabat has invented a mechanical razor, which, in principle, is something like a lawn mower A helix, with steel blades tangent to a comb, is made to rotate by means of a flexible chain worked by a lever. One man works the lever, while the "operator" promenades the comb over the body of the animal, regulating the length of hair to be left by the inclination of the comb. It is said that horses and beasts enjoy being clipped by machinery. It, however, remains to be seen whether humanity will.

PARLIAMENTARY NOTES.

IN considering the bill for the Regulation of Railways, the House of Lords lately discussed the question of smoke-burning locomotives, which discussion was brought about by the fact of a railway company having been fined and unfined for allowing an engine to smoke which was constructed so as not to smoke. Let us state the case as put by the Duke of Richmond, who observed that, as the law now stood, every locomotive engine that used coal was required to be constructed on the principle of consuming, and so as to consume, its own smoke, and if an engine were not so constructed the company to which it belonged was liable to a penalty of £5 for every day during which it was used on their railway. A case had arisen as to the law on that subject, in which the Manchester, Sheffield, and Lincolnshire Railway Company was concerned. The magistrates convicted the company because one of its engines emitted smoke; but, on an appeal to a higher Court, the Lord Chief Justice and two other judges decided that the engine, being constructed to consume its own smoke, complied with the terms of the Act, and therefore they reversed the decision of the magistrates. In that, as in most instances, it was well to alter the existing law as little as possible, because, without due care, they might weaken rather than improve it. By the proposal of the Government the liability would remain upon the railway company, as at present, of constructing their engines upon the principle of consuming their own smoke; but if the company showed that this had been done, it would be an answer as far as they were concerned. The driver of the engine, however, through whose fault smoke had been emitted, would be liable for such neglect to a penalty not exceeding 40s.

Earl Grey hoped the noble duke would reconsider the decision he had arrived at. If the penalty were recoverable merely against the engineers and stokers, how were the persons complaining to discover the persons guilty of the offence? Cases had been brought under the notice of the noble duke in which persons had been exposed to great inconvenience, and their houses rendered almost uninhabitable by the continuing nuisance of engines vomiting clouds of smoke. Few people like to be put in the position of prosecutors, but one gentleman who had taken up the question energetically, thereby made himself obnoxious to the engine-drivers, who inflicted upon him every petty annoyance they could. Railway companies had a remedy in their own hands, for they had the power of dismissing their own servants, whereas the only remedy which the public could have lay in making the company responsible. In London the penalties against engines which did not consume their own smoke had never been enforced till the duty of enforcing them was placed in the hands of the police, and the odium thereby removed from private prosecutors. The clause of the noble duke really did not strengthen the law as it now existed at all.

The Duke of Cleveland said that the law was plain enough, but what was really wanted were facilities for carrying the law into execution. At present railway companies could afford to run the risk of an information being laid against them, because they knew that, practically, persons would not take the trouble to do so.

Lord Redesdale also thought it would be better to transfer the penalty from the driver to the railway company, and that the penalty might be advantageously increased from 40s. to £5. In other respects he approved the clause.

The Marquis of Salisbury believed that a penalty directed against the driver himself would be more likely to frighten him than one directed against the company; and it was through the carelessness of drivers that emissions of smoke mainly occurred. Their lordships, however, must not suppose that they could succeed in all cases in preventing this. While a train was in motion it was perfectly feasible to prevent smoke from being emitted, but, by a higher law than the omnipotence of Parliament, locomotives stopping still, when the fire at the same time required to be replenished, could not be prevented from sending out a certain quantity of opaque smoke. The wording of the clause suggested by Earl Grey was of Draconic stringency, for the penalty was to attach "every time that smoke was emitted," meaning, he supposed, every puff.

Matters were soon adjusted by the Lord Chancellor observing that there was a defect in one of the clauses of the Railways Clauses Act, 1845, which provided that locomotives should be constructed upon the principle of consuming their own smoke, but did not go on to say that, whenever practicable, they should actually do so. It was very desirable that this defect should be remedied, and the clause as now proposed by the Government would have that operation. As regarded the imposition of the penalty, the best course probably would be to make the railway company responsible in the first instance, leaving them to settle matters, as they would doubtless take care to do, with their own servants. After this the clause as amended was then agreed to. So railway companies know what they will soon have to expect.

In the House of Commons, at the close of last week, an amusing discussion occurred about the "Glutton," a vessel of which we then heard for the first time. The question was put by Captain Mackinnon, who asked the First Lord of the Admiralty if it was true that a vessel of only 2,700 tons, the "Glutton," could be built to carry two 25-ton guns, with from 12in. to 14in. of armour, to be available for the Mediterranean or wherever required, of what use would any of our four, five, or six thousand ton broadside ships be against her, with their 8in. and 9in. armour, except to run away; why should the "Glutton" turret-ship have only nine knots speed when the "Hotspur" ram, of less tonnage, was to have twelve knots; had Captain Coles been consulted or allowed to see the drawings of the turret-ships proposed and those now building for our colonies; and why should not the turret-ship "Glutton" be a ram as well as the "Hotspur"?

Mr. Corry availed himself of this opportunity to make an explanation with reference to the name of one of the vessels which, as it stood in the question of the hon. and gallant member, was not very complimentary to the good taste of the Admiralty. They might hope that if the ship in question should ever be engaged in action it would prove a very "glutton" in the fray; but, in fact, her name was not the "Glutton," but the "Glatton," and she was so called after a vessel, which, in the last century, performed some very extraordinary service in consequence of the large calibre of her guns. He would observe that vessels intended for defensive purposes were built on principles which were wholly inapplicable to vessels intended as seagoing ships in all weathers. He was quite certain the Controller of the Navy would be very grateful to the hon. and gallant member if he could show him how seagoing ships and ships constructed for defence could be made to combine the qualities of both. The drawings of the turret-ships proposed were in a forward state, and would be referred to Captain Coles.

Our ammunition does not appear to be quite up to the mark, for Mr. Herbert has had to ask the Secretary of State for War whether it was the case that the brigade of Guards had very lately been obliged to abandon the usual annual rifle practice at Aldershot, on account of some serious defects in the ammunition, which caused some of the rifles to burst, and others to be so damaged as to be

Digitized by Google

useless; what was the cause of such serious defects; had any casualties happened to the men on account of them; how many rifles were damaged; and what steps would be taken to remedy these evils for the future?

Sir J. Pakington admitted that the accidents referred to had occurred, but he was not prepared to allow that they had been caused by any defects in the ammunition. One barrel had burst, and four others had been very slightly damaged. They had endeavoured as clearly as possible to trace the cause; and in one instance certainly—he believed in more than one—the accident was caused by a cartridge being defective. Then, Sir John *must* admit that there are defects somewhere in the ammunition. They had a most anxious desire to ascertain as far as possible whether there was any serious defect in the cartridges now in use. 7,000 of these had been sent out for immediate trial. The whole of the 7,000 were fired off, and no very serious defects in them were apparent. The War Department were endeavouring to ascertain whether any improvement could be effected upon the present composition of the cartridge, and he could assure the hon. member that no pains would be spared in endeavouring to supply the army with the most safe and useful cartridges that could be made. He was happy to say that, with one trifling exception, no casualties had happened to the men.

LAUNCH OF THE ARMOUR-CLAD TURRET-SHIP "MONARCH."

MONDAY last witnessed the completion of the first armour plated ship constructed on the turret principle at a Government establishment by the launch, or, more correctly speaking, the floating out of dock, at Chatham dockyard of the ironclad ship "Monarch." Although the "Monarch" is designated a turret-ship, yet, beyond carrying some portion of her powerful armament in two turrets, rising an enormous height above the water, there is little to distinguish her from an ordinary ironclad ship, of the broadside type, the main and generally accepted features of the true turret principle, as advocated by Captain Cowper Coles and other supporters of the turret theory, being altogether wanting—rendering, in fact, this last creation of the Admiralty a sort of nondescript vessel, of a cross between a broadside and a turret, while the distinguishing features of both are wanting. As a mere powerful mass of iron and wood the "Monarch," in her form of construction, surpasses any vessel yet built for the Admiralty—not even excepting, perhaps, the "Hercules," the last completed vessel at Chatham—but whether her ultimate performance, either at sea or in action will justify the quarter of a million sterling she will cost the nation is a problem which can only be satisfactorily worked out by time. Although the "Monarch" has been built from the designs furnished by Mr. Reed, it is only due to the Chief Constructor to remark that the present and former Boards of Admiralty are to be credited with all the numerous alterations and "improvements" effected from time to time in the first turret-ship produced by the Admiralty, the result being that the "Monarch" is already condemned as a turret-ship by Captain Coles, who is now building the "Captain" to show what a vessel constructed on the actual turret principle should be. In the construction of the "Monarch" Mr. Reed has adopted the bracket frame system, first introduced by the Chief Constructor in the "Bellerophon," and since adopted in all the iron turrets of war built in this country for our own and foreign governments. The ordinary features of this system of construction may be briefly described as a double cellular bottom, water-tight bulkheads and platforms, and iron decks, which combines lightness and strength to such an extent as enables the naval architect to greatly diminish the proportion formerly considered necessary between the weight of the hull proper and that of the defensive material carried. With the exception that the towering broadsides of the "Monarch" are destitute of ports, the arrangement of the armour-plating on the hull is very similar to that adopted in a broadside ironclad ship with a central gun-deck battery. It is, however, to the enormous height of the upper deck of the "Monarch" above the water for a vessel built on the turret principle, and the crowding of the forward upper deck with a high forecastle, that the advantages claimed for a turret-ship are rendered almost, if not entirely, nil. Instead of being waterborne some 2ft. or 3ft., the upper deck of the "Monarch" rises 14ft. above the water-line, while the turret-guns will be carried at a height of no less than 17ft. above the water. To protect the dead surface of the vessel's broadside, which will present so tempting a mark to the guns of an enemy, the sides of the "Monarch" amidships are protected by armour-plates 7in. in thickness, laid on a backing of teak of 12in., with an inner skin plating, in two thicknesses, of 1¼in., the whole being further stiffened and supported by 12-inch longitudinal girders worked outside the skin plating, and 10-inch vertical frames worked inside, both sets of stiffeners being placed at intervals of a couple of feet. A belt of armour-plating of 6in. in thickness extends below the water-line. Athwart the vessel, fore and aft, armour-plated bulkheads are constructed, corresponding to those usually placed at the ends of the central battery in a broadside ship. The armour bulkheads are similar in their construction to the sides, with the exception that the armour is from 4in. to 5in. thick, and the backing 10in.; the space amidships, thus enclosed, being protected from the upper deck down to about 5ft. below the water.

The "Monarch" will carry her turrets in the protected space in the centre of the ship, the turret-bed being built on the main deck, the protected portion of the turret beginning just at the level of the upper deck. Each turret is 26ft. in diameter, and both will mount two 25-ton guns, for the working of which ample space is provided. The turret-guns are protected by means of 10-inch armour-plates, on a wooden backing of 8in., with a skin plating all in two thicknesses, each ⅜in., stiffened by 7-inch horizontal frames, with an iron lining of ⅝-inch plating on the inside. In addition to the armour-plating of the sides, there are inside screens of iron plating to further protect the machinery of the turrets. At the portions of the turrets away from the guns the planking is 8in. in thickness, laid on 10in. of teak. To enable the turret guns to obtain a clear range, the bulwarks are made to fold outwards, while the fire of the guns will be interfered with as little as possible by the number of the shrouds to the lower masts being considerably reduced, compensation being made for the loss of support thus entailed by increasing the dimensions of the iron masts. From the circumstance of the Admiralty insisting on the "Monarch" carrying a forecastle on the upper deck, the guns in the forward turret cannot be fired at a less angle than 10deg. with the keel, while they have a limiting angle of the same amount in their training aft. In the after turret the guns can be fired at an angle of 10deg. with the keel towards the bow, and 6deg. towards the stern, the latter limit being determined by the space required for the deck fittings, stowage of boats, &c. In order, however, to obtain a direct fore and aft fire, the "Monarch" carries protected batteries at the bow and stern—a novelty altogether unique in a turret ship. On the upper deck the bow battery will contain two 6½-ton guns, each of which can be fired at a training of 3deg. within and 76deg. from the line of the ship's keel. In the stern battery, on the main deck, will be placed one 6½-ton gun, fought from a right-aft port, and having a range of 15deg. on each side of the line of keel.

The "Monarch" is a few feet longer than the "Hercules," the last-constructed ship at Chatham, the following being her principal dimensions:—Length between perpendiculars, 330ft.; extreme breadth, 57ft. 6in.; depth in hold, 18ft. 8in.; draught, with all her weights on board (forward), 22ft. 6in.; ditto (aft), 26ft. 3in.; burden, 5,098 70-94ths tons; launching displacement, 4,450 tons. The first plate for the keel was placed in the graving dock on October 21, 1866, and the "Monarch," which has thus been only nineteen months building, left the dock on Monday with the whole of her armour-plating, amounting to 1,152 tons, bolted to her sides and bulkheads. In her form of construction arrangements have been made to enable the "Monarch" to be used as a ram, the bow being specially strengthened for this purpose, while the handiness of the ship, both as a ram and under ordinary circumstances, is increased by the adoption of the balanced rudder as fitted to the "Bellerophon." As the "Monarch" is intended essentially for a seagoing ship, and space is provided for only some nine or ten days' consumption of coal at full steaming, she will naturally have to depend to a great extent on her sailing powers. She will accordingly be a full-rigged ship, arrangements being made to enable her to spread a large surface of canvas, by which means she will thus keep her place in a squadron under sail. Her lower masts are of iron, and her topmasts and yards of wood, made in the Chatham Dockyard, the main and foreyard being each 105ft. in length. The iron masts are the strongest yet manufactured for a vessel of war, the rigging being occasionally required to be let go to clear the ship for the fire of the turret guns.

The ceremony of christening the "Monarch" was allotted to Lady Cecilia Bingham, sister of Lord H. G. Lennox, M.P., Secretary of the Admiralty. From the circumstance of the "Monarch" being built in a graving dock, the ceremony attending the launching was unattended with the interest usually attaching to the launch of a large vessel of war. At the head of the dock a platform had been erected for the accommodation of visitors, and the officials connected with the Admiralty. Shortly after two o'clock, Lady Cecilia Bingham was conducted by Lord H. Lennox and Mr. Thornton, master shipwright, to the bow of the "Monarch," and having named the ship with the usual ceremony, the huge vessel was slowly hauled out of dock and safely moored in the harbour, amid the cheers of the spectators, the band playing "Rule Britannia." The launching draught was that indicated by the designer. The "Monarch" will at once be fitted with her engines and machinery, by Messrs. Humphrys, Tenant, and Co., consisting of a pair of direct-acting engines of 1,100-horse power (nominal), but capable of developing a power of 6,600 horse. The engines are fitted with all the latest improvements, and they are constructed to drive the vessel at a mean speed of fourteen knots per hour. The "Monarch" will be equipped for her first cruise at sea with all despatch.—"Times."

ON SOME NEW EXPERIMENTS ON LIGHT.*

By J. H. GLADSTONE, Ph.D., F.R.S.

THE speaker commenced by referring to the fact that we are constantly making new experiments or observations on light: in fact, all seeing is but a comparison of different degrees of light and shade, and the contrast of colours. Most of the rays that meet our eyes from surrounding objects are reflected rays, but some of the commonest things, such as the water-bottles and tumblers of cut-glass on our dining tables, exhibit beautifully the bending, the magnifying, the diminishing, and the production of coloured fringes, due to refraction. The purpose of this discourse was to rise from the simplest phenomenia of this kind to a consideration of refraction-equivalents, and to describe the state of our present knowledge in regard to them.

By means of the electric lamp it was shown that a piece of glass, or other transparent body, will throw a perfectly black shadow if the two surfaces through which the ray passes be not parallel; that the light is then bent on one side, and at the same time spread out into its component colours; that this bending (refraction) varies with the amount of inclination of the two surfaces to one another, but in such a way that the sine of the angle of refraction bears a constant ratio to the sine of the angle of incidence; that this constant number, termed the index of refraction, or μ, belongs only to the one substance, each solid, liquid, or gas having its own index; that there is no necessary connection between the amount of refraction and the length of the spectrum (dispersion) caused by different substances, whether gaseous, liquid, or solid—for instance, a solution of an iodide always disperses more than a solution of the chloride of the same metal, even though it be diluted to the same amount of refraction.

This index of refraction is affected by change of temperature. In liquids, and probably in all gases the bending decreases as the thermometer rises; in solids, on the contrary, as lately shown by Fizeau, the change is in the opposite direction, crown glass always remaining the same, and fluor spar being the only case where he observed a diminution. This was experimentally demonstrated in regard to liquids. Thus a yellow sodium ray, which had passed through a hollow prism filled with oil of nutmeg, and thence through another filled with bisulphide or carbon, moved some inches along the screen, when the nutmeg oil was warmed a few degrees by stirring it with heated iron wire. This index of refraction is still more materially affected when a body passes from the solid to the liquid, or from the liquid to the gaseous condition; a fact that was illustrated by the visibility of the water melted in crystalline spaces in the middle of a block of ice.

The index of refraction of a mixture is moreover not always the mean of the indices of its constituents. Thus a ray passed successively through two hollow prisms filled with equal quantities of alcohol and water respectively, fell on the screen in a certain position; but when the two liquids were mixed together, and divided between the two prisms, the ray was visibly reflected to a greater distance.

These changes depend on the alterations of volume which the substances undergo; and the speaker, in conjunction with the Rev. T. Pelham Dale, has observed in liquids that the index of refraction, minus unity, divided by the density (in symbolic language $\frac{\mu-1}{d}$) is constant for all temperatures, and for all mixtures, or rather that the coincidence is very close but not quite perfect on account of some other law not yet understood. This conclusion has been abundantly verified by Landolt of Bonn, Ketteler, and Wullner, and the former experimentor has founded upon it a method of analyzing mixtures of liquids.

This unchangeable number was termed the "specific refractive energy" of the substance, and it seemed to hold good notwithstanding a change from the solid to the liquid or the gaseous condition. It was early observed that the specific refractive energy of a compound bore a close

* Read before the Royal Institution.

Digitized by Google

resemblance to the mean of the specific refractive energies of its components. Landolt, by multiplying this number by the chemical equivalent, facilitated the calculation greatly. He termed this new number the "refraction-equivalent," $P \frac{\mu-1}{d}$, and proofs have rapidly accumulated that the number is affected, not only by temperature, change of aggregate condition, mixture, or solution, but even by strong chemical combination.

Thus diamond, which is crystallized carbon, has the refraction-equivalent 5·0; sulphur has 16·0. Bisulphide of carbon, C S^2, which is nearly the most refractive liquid known, should therefore be represented by $5 + 2 \times 16$, that is 37·0. The experimental number is 37·3. But the diamond will burn in oxygen, and it is thus converted into carbonic anhydride, while it is possible to reduce this gas into another containing only half the amount of oxygen, namely, carbonic oxide. The refraction-equivalents of these gases, as deduced from Dulong's observations, are respectively 10·03 and 7·53; but the difference between C O_2 and C O is one equivalent of oxygen, and the difference between the above numbers is 2·5. This, then, may be taken as the refraction-equivalent of oxygen, and subtracting it from C O = 7·53 we have remaining C = 5·03, practically the same number as that obtained directly from crystallized carbon. Similarly, but generally by more indirect methods, it has been determined that this element, whether pure as diamond or combined with other elements to form gases as the above-mentioned, coal-gas, or cyanogen, or liquids as chloride of carbon, benzole, oil of turpentine, alcohol, or ether, or solids as paraffin, sugar, or camphor, is still exerting the same influence on the rays of light that set its particles in motion, an influence that we can express by the number 5·0.

Again to revert to sulphur, the two salts sulphocyanide and cyanide of potassium—K S Cy and K Cy—differ by one equivalent of this element, and their refraction-equivalents, as determined from their aqueous solutions, are respectively 33·4 and 17·1, numbers differing by 16·3, a number almost identical with that reckoned from molten sulphur. In this way the refraction-equivalents of a large number of the elements have been determined; and the following table comprises what seem the most probable numbers among those that have been hitherto published by Landolt, Haagen, and Schrauf, as well as the speaker:—

	Atomic weight.	Refraction-equivalent.
Hydrogen	1·0	1·3
Chlorine	35·5	9·8
Bromine	80·0	15·7
Iodine	127·0	24·4
Oxygen	16·0	3·0
Sulphur	32·0	16·0
Carbon	12·0	5·0
Silicium	28·0	6·2
Nitrogen	14·0	4·1
Phosphorus	31·0	18·5
Arsenic	75·0	6·0
Antimony	122·0	25·7
Vanadium	51·4	2·4
Sodium	23·0	4·9
Tin	118·0	19·2
Copper	63·4	11·8
Mercury	200·0	21·0

The above numbers are reckoned for the red ray. Most of them can as yet claim to be considered only as approximative; and it seems certain that some elements, as oxygen and sulphur, have more than one refraction-equivalent. Vanadium, though included in the above table, has only just been determined, and that from the oxy-trichloide which Professor Roscoe exhibited a few weeks before. It is interesting, as it supports his theory of the close analogy of phosphorus and vanadium, for these two bodies, with sulphur, exceed all others in refraction and especially in dispersion. The speaker stated that he was now engaged in examining the effect of salts in solution on the rays of light, and that he hoped to determine in this way the refraction-equivalents not only of a multitude of salts, but of the metallic elements themselves.

But the question may be asked, "If a substance has a refraction compounded of the refractin of its constituents, how can bodies such as Iceland spar have two refractive indices?" Now these are crystalline bodies, or if uncrystallized they have become doubly refracting by being unequally heated or compressed. In either case we may suppose a different amount of tension in different directions; and the fact of the two rays being oppositely polarized points to some such difference of molecular arrangement. It is easy to understand that the change of tension or internal structure may act in the same way as a change of density in modifying the velocity of transmitted light, and therefore the amount of its refraction. But if we take the crystal to pieces by dissolving it, there can then no longer be unequal tension or unsymmetrical arrangement of particles, and it must have one refraction-equivalent. And this is always the case. The numbers deduced from Brewster's observations of the two rays of crystallized nitre are 16·3 and 25·0, while the equivalent of nitre dissolved in water is the intermediate number 21·8.

McCULLOCH'S MICROSCOPE.

ONE of the most fascinating and improving pursuits is the study of nature through the microscope. Hitherto this enjoyment has been limited to those who could afford to purchase it at a high cost. Now, however, it is thrown open to the million by means of a very powerful but cheap microscope which has been invented and is made by Mr. A. McCulloch, of 18, Blucher-street, Birmingham. This instrument is divided into four parts, viz., the eye-piece, composed of two screws, in the centre, or between which, is placed the lens or magnifying glass; 2nd, the object-glass, on the centre of which the objects are placed, and which is fixed to No. 3, or the body or tube; 4th, the condenser of natural light, at the extreme end, which is to be used only by daylight, and taken off by gaslight, when the open end of the tube is pointed towards the gas or candle light to receive the rays direct. In inspecting objects by daylight with the condenser on, the observer must look towards the sky to get a light. This apparatus is of small size, but withal exceedingly powerful, magnifying about 30,000 times. Mr. McCulloch has devoted considerable time and attention to the special subject of single-lens making, and has been eminently successful in producing a good lens, as the microscope in question testifies. We have tried one of them, and its power and simplicity combined with its cheapness induce us to recommend it to all who are debarred the luxury of the larger instruments by reason of their expensiveness. As a pocket companion, no student of nature should be without one.

CENTRAL HORTICULTURAL SOCIETY.

AT the ordinary bi-monthly meeting of the members of this institution, held at Dr. Johnson's-rooms, Essex-street, Strand, on Tuesday last, Mr. Joseph Newton, of H. M. Mint, read a paper on horticulture and floriculture. After expatiating at considerable length upon the civilizing effects of the two branches of science in question, and pointing out the great value of the cottage allotment system to rural communities and the public generally, Mr. Newton proceeded to explain the law of diffusion as affecting the growth of plants. He clearly showed that many of the phenomena in regard to floral vegetation owed their existence to the action of this law, and gave many practical hints with regard to the ventilation of hothouses and conservatories. The reader also referred to the commercial value of vegetable products, and to the vast influence which floriculture had exercised upon the decorative and industrial arts in this and other countries. Painting, sculpture, and poetry, Mr. Newton said, were likewise deeply indebted to horticulturists and florists. The paper was listened to with much attention throughout, and at its termination a vote of thanks was unanimously awarded to the author.

A NEW EXPEDITION TO AFRICA.

A NEW African exploring expedition has been organized in Dublin by Captain Faulkner, who first proposed it, and Captain Norman, late of the 69th Regiment, who writes to the "Express" on the subject. Captain Faulkner states that he regretted being able to explore only a few miles of Lake Nyassa when engaged in the Livingstone search expedition in September last, and that he resolved to return at some future period. He will also be accompanied by Captain Casement, late of the 14th Regiment; Captain Gubbins, late of the 56th Regiment; and Mr. Perrin, an engineer in the shipbuilding yard of Messrs. Walpole, Webb, and Bewley. A small steam yacht has been built for the party by Messrs. Walpole, and is intended to be used in pursuing the exploration of Lake Nyassa from the point where Dr. Livingstone was last heard of. She is named the "Faugh-a-Ballagh," and Captain Faulkner says of her:—"The boat now ready for us, which is a credit to her Irish builders, both for the rapidity and perfection of their work, is a curiosity well worth seeing, and I have not a shade of doubt that she is well suited for the navigation of the rivers Shire and Zambesi, as well as the stormy Lake of Nyassa, and that no difficulty will be experienced in carrying her past the cataracts. The following are her dimensions:—Length, 50ft.; beam, 11ft. 6in.; depth moulded, 5ft. 6in. She is put together in sections, consisting of seventy-five sections, with over 8,000 bolts and nuts. Her engines are 8-horse power, and she will be propelled by one of Griffith's three-bladed propellers." Everything for the expedition has been provided in Dublin. The party will set out from Southampton on June 9 in the Union Company's Cape mail steamer for Natal, where they will charter a vessel to take them to the mouth of the Zambesi, and thence they will follow the track of the late expedition. Their first object will be to reach the extreme north, where they hope to hear of Livingstone, should he have abandoned the idea of coming down the Nile, and perhaps be on his way to Zanzibar

PENCIL-LEAD MINES AND LEAD PENCILS.

EVERYONE knows what a black-lead pencil is, but it is not generally known that there is not a particle of lead in the pencil. The material variously known as black lead, graphite, or plumbago, is almost wholly composed of carbon. It probably owes its misnomer to the fact that, previous to the employment of graphite for making pencils common lead was used, and this within the present century. For a long time the best graphite was obtained, not in very large quantities, at Borrowdale, in the English county of Cumberland, where it was discovered in 1564, early in the reign of Queen Elizabeth, and pencils, much like those still in general use, were produced in the year following. As the supply of the graphite (known in Cumberland, while in the mine, by the title of wad), was not large, the British Government, from the first, took great pains to prevent the exportation of the article, and even to limit its home sale to a supply just sufficient to meet the estimated demand. Graphite is found in various parts of Europe, and even in North America, but of very inferior quality. The Cumberland mines were worked only a few weeks in each year, yet the yield of wad was estimated at £40,000 a year. While the graphite lasted, England had a monopoly in supplying the best pencils to the world. Year after year, for a century past, the graphite deposit in Cumberland became "fine by degrees and gradually less." The result was that graphite powder had to be compressed into a solid cake from which pencils could be supplied. A French variation, said to be an improvement, was to mix the powdered and purified graphite with clay, which is largely done still.

Nearly 150 years ago, the pencil manufacture commenced in England, and improved in France, was transplanted to the village of Stein, near Nuremberg, in Bavaria, and, little more than a century since, Casper Faber there began to make the pencils which continue to be made by his descendants, and bear the family name through the world. The present John Lothair Faber, great grandson of Casper, has been head of the firm since 1839, and is not only very wealthy, but has recently been ennobled by the King of Bavaria. One of his brothers is associated with him at Stein, in the processes of manufacture; the youngest of the three, Eberhard Faber, represents the firm, for the Western World, at New York. Stein is literally a town of pencil factories, of which Baron Faber is the ruler, taking care of the health, government, education, industry, thrift, and amusements of the inhabitants, and always living in their midst.

It may be asked, how do the Fabers make lead pencils without the famous graphite from Cumberland? It appears that twenty years ago, John Peter Alibert, a Frenchman, resident in Asiatic Siberia, having heard of the gold discoveries in California, began to examine the sandy beds of various rivers flowing into the Arctic Ocean. He found samples of pure graphite, evidently brought a considerable distance by force of the stream, in one of the mountain gorges near Irkurtsk, and, pursuing his discovery, tracked back to a branch of the Salan Mountain range, on the very summit of Mount Batougol, 275 miles west of the town of Irkurtsk, near the Chinese frontier, in the midst of the rocky desert, and found pure graphite. After years of costly labour, Alibert found an exhaustless deposit of graphite equal to the best ever taken from Cumberland. Beside decorating and rewarding him, the Russian Government changed the name of Mount Batougol to that of Mount Alibert. Nearly every crowned head in Europe has honoured him. With the consent of the Russian Government, Alibert now supplies Faber's house exclusively with graphite from the mine in Asiatic Siberia. Pencils of this material were first made by Baron Faber in 1861, and were not introduced into the American market until 1865, from which time artists and others perceived and acknowledged their superiority. If the world were to endure a thousand years more, there is graphite in Mount Alibert to supply its population with good black-lead pencils.—"Philadelphia Press."

THE DISINTEGRATOR.

BY MR. THOMAS CARR.

SCALE ONE INCH TO THE FOOT.

FIG. 1.

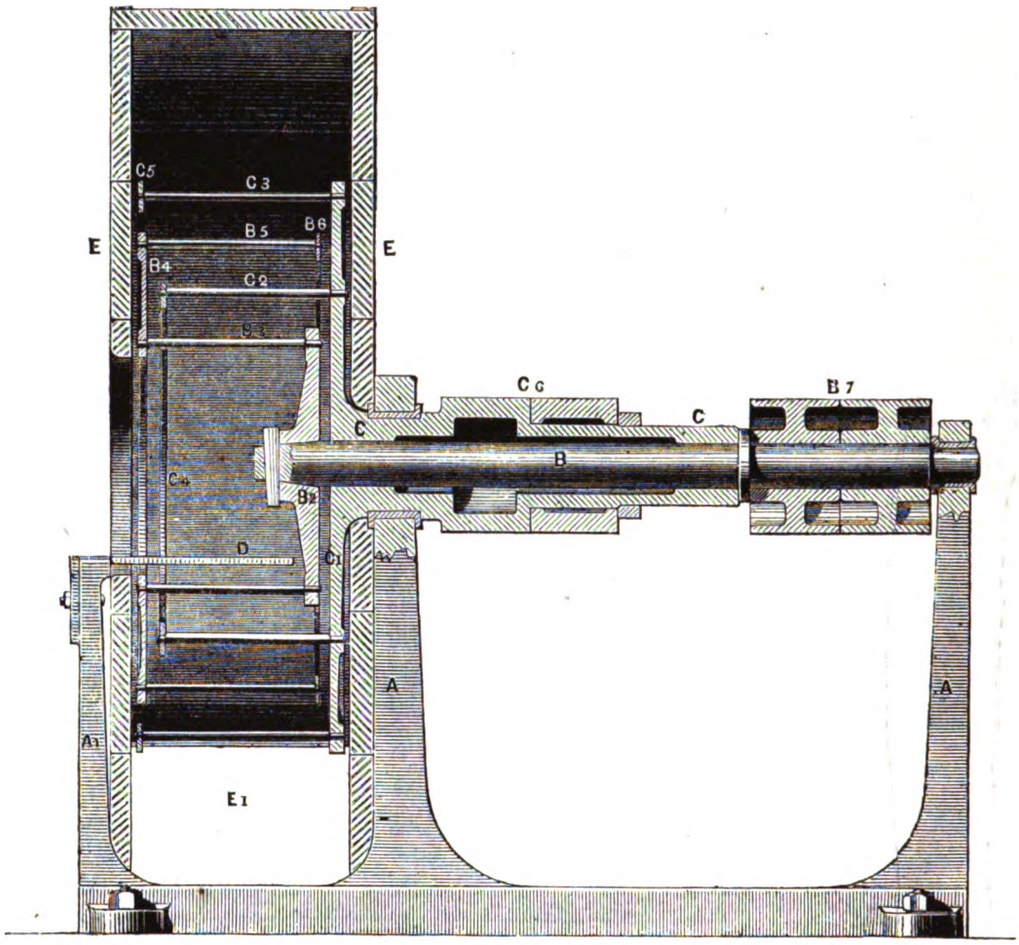

FIG. 2.

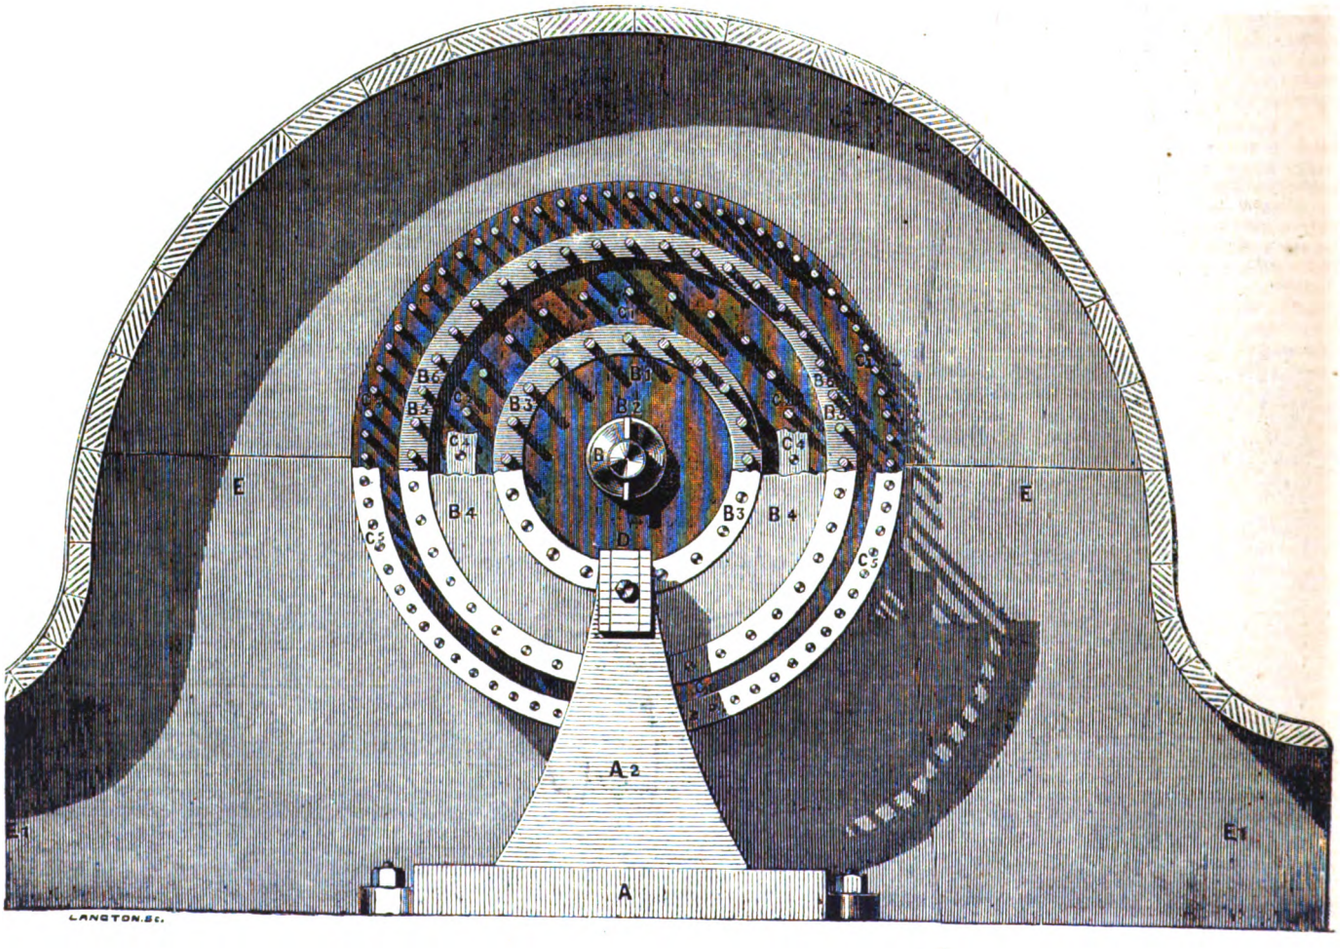

Digitized by Google

CARR'S DISINTEGRATOR.

ON the opposite page we illustrate a very ingenious and efficient disintegrator, the patented invention of Mr. Thomas Carr, of Montpelier, Bristol. This machine, which has come into very extensive use, thoroughly breaks up, pulverizes, and perfectly mixes from sixty to seventy tons per day of either hard and dry, or soft and damp conglomerated phosphates, guano, &c., without any inconvenience from becoming clogged or choked in the operation. It consists of a series of four strong cylindrical iron cages, of various sizes, concentrically arranged one within another, on a horizontal axle, on which they are caused to revolve with great velocity in contrary directions to each other, by means of an open and crossed strap, the alternate cages being so arranged to intersect one another, that while, in reality, there are only two motions, there are relatively four—the first and third cages going to the right, the second and fourth to the left; one set being in a piece with the hollow axle or boss on which the cross strap is placed, and the other set keyed on to a solid shaft working within, on the outer end of which is the pulley of the open strap.

The material to be pulverized in its rough, lumpy condition, is fed through a central opening into the innermost cage, and is instantly delivered in a radiating shower from every part of the periphery of the outermost one into an external casing or hood, in a state of fine granulated powder. The granulating, or pulverizing, is effected in the following manner:—The centrifugal action of the machine drives the material from the centre to the periphery of the outermost cage; but before it can reach and escape from there, every grain of it meets with and receives four distinct cutting blows, delivered with great rapidity and violence, by the numerous (156) but open set bars of the intersecting cages that it encounters on its way, each of which blows is doubled in intensity by the four reverse actions of the several cages. A stout knife is fixed to a pillar, cast in a piece with the carrying frame, in such a manner that its blade extends into the interior of the innermost cage, which instantly arrests and cuts such pieces as are otherwise too large to pass between its bars. Immediately this first cage is passed, any unfibrous substance, if less tenaciously pasty than dough, or not much tougher than oilcake, or any brittle material, such as bone ash, boiled bone from the size makers, chemical crystals, coal, &c., is, in less than a second, thrashed, cut, and beaten to pieces, and the whole of it driven out with great force from the periphery in fine powder; which can be made either finer or coarser by increasing or diminishing the rotating speed: for it must be borne in mind that its pulverizing powers are in direct proportion to its speed.

In our engraving, fig. 1 is a longitudinal elevation in section, in which all the bars forming each cage, except the two in each cage which occur at the sectional line of the drawing, are omitted to avoid confusion; fig. 2 is an end elevation of the machine, one half of the outer end disc being broken away to show the cages more distinctly, the casing being also shown in section. The machine consists of a frame or headstock A, which can be bolted down to a suitable bed of stone or wood by bolts passing through the ears A^1. This headstock A forms the bearing of a solid shaft B and hollow boss or shaft C. The solid shaft is conical at the end, and carries a disc plate B^1, which is firmly secured to it by a key B^2 passing through a slot in the end of the shaft B. This disc plate B^1 carries a series of bars B^6 which are riveted into at one end, and at the other end in another disc B^4, in which one end of another series of bars B^5 are secured, the other end of these bars being connected together in a ring B^6; thus two circular cages, formed by the series of bars B^3 and B^5, are obtained, which will rotate with the shaft B. The hollow boss C working loose on the shaft B is solid, with the disc or face plate C^1 which carries the series of bars C^2 and C^3 forming the cages intermediate and alternate with the cages formed by the bars B^3 and B^6, and the outer ends of the bars C^2 and C^3 are respectively connected and secured in the rings C^4 and C^5. The shaft B and hollow boss C are rotated in opposite directions by belts (one of them being crossed and the other open) working on the fast and loose driving pulley B^7 and C^6. The hollow boss C is lubricated by passing the lubricating matter through holes formed in it, which are closed by screw plugs to prevent the lubricating matter from being thrown out when at work by centrifugal action. A standard A^2 from the headstock or frame A carries a bar or knife D, the object of which is to break up such lumps as will not pass between the bars of the internal cage. The covering E for the cages is made of wood, and in two parts, the upper part being arranged so that it can be readily removed by lifting it off from the lower part when the cages require to be got at. This cover has an opening opposite the internal cage, through which the material is passed which is to be operated upon, and openings are also left in the casing E at E^1 for the removal of the material disintegrated.

The ingenious nature and practical value of Mr. Carr's Disintegrator demand a few words from us respecting the principles upon which it is based. It differs widely from any of those principles on one or other of which all other mills, for whatever purpose, are constructed, in neither cutting, rasping, crushing, grinding, stamping, or tearing, but producing the required results solely by a continuous rotatory series of unarrested blows, striking in opposite directions the free unsupported materials in such a manner that, there being no unyielding medium to absorb, like an anvil, the surplus energy of the shock, the machine meets with no resistance but that which is justly due to the act of overcoming the cohesive strength and *vis inertia* of the material it is shattering. The heavier and more obdurate the materials operated on, the more severe the blows, and *vice versa*. Thus the rare desideratum is attained of having no expenditure of power beyond what is strictly equivalent to the effect produced. The machine combines in an advantageous manner direct with centrifugal force, for the same blows that destroy the cohesion of the material struck communicates to its fragments a tendency to escape from the machine immeasurably greater than mere gravity could give. Consequently, scarce a second of time can elapse after a shovelful is thrown in before the machine has thus freed itself entirely, and is ready for another. The reverse action of the several cages, it will be seen, not only doubles the force of each blow by giving it the aggregate impulses of the opposing cages, but, at the same time, quadruples the number of the blows. If the four cages revolved together in the same direction, the material, when struck by the bars of the first cage, would fly out at a tangent from the periphery, and thereby escape through the succeeding cages almost without further molestation.

The peculiar manner in which the material is struck, as it were, in mid air, and its constituents widely dispersed, as if suddenly under the influence of a mutual repulsion, renders the machine invaluable for such claggy materials as soluble phosphates, which it not only divides to an infinitesimal extent, but also from the peculiar manner in which it appears to charge them with air, greatly increases their bulk and specific lightness; and in a great measure prevents all future tendency to reunite, whereas the usual defect of other machines, as is well known, is their tendency to knead such materials into a closer and denser mass, and make them more pulpy and pasty than ever. For these and other characteristic advantages peculiar to itself, the disintegrator may not unjustly claim the credit of occupying alone a void in mechanical appliances hitherto unfilled; and of having a distinct individuality and sphere of usefulness of its own. This usefulness has been fully recognized in the general adoption in all parts of England and on the Continent of the disintegrator for the purposes to which we have alluded. Amongst other users we may mention Messrs. J. B. Lawes and Co., of the Chemical Manure Works, Deptford Creek, where, to our knowledge, the disintegrators are giving perfect satisfaction. Larger sized ones, capable of pulverizing thirty tons an hour of hard materials, are also coming into extensive use at manufactories of fire-bricks, sanitary tubes, tiles, potteries, metal smelting works, patent fuel and sugar factories, &c.

THE RANEEGUNGE POTTERY WORKS.

ALMOST imperceptibly, and within a short space of time, what may be called a new branch of industry has sprung up amongst us, says the Calcutta "Engineers' Journal." No one who has seen the bricks, tiles, and other earthenware manufactured by the Raneegunge Pottery Company, will, we think, disagree with us when we call their manufacture a new branch of industry in Bengal, instead of connecting it with the manufacture of those specimens of half-burnt, mis-shaped pieces of clay that we in Calcutta are accustomed to call tiles. The company is a limited liability company, and will be looked upon by many as being in consequence ephemeral; but if the importance of the objects it has in view, and the facilities for attaining those objects which are presented at Raneegunge, be taken into consideration, the shares of the company appear to us to be a most promising investment. So long ago as 1860, specimens of the clay were sent home, and forwarded to managers of pottery works, in various parts of England, with a request to have the clays fairly tried, and that a report of their fitness or otherwise for the purposes intended should be afterwards submitted. These reports were universally favourable as to the quality of the clay; and the question of the establishment of the company turned altogether upon the fitness or otherwise of the Raneegunge coal for the purpose of firing the more finely glazed description of earthenware. The conclusion arrived at seems to have been that the coal was suitable, because we see that this company has started, and we have seen specimens of their work—glazed, unglazed, and vitrified—and they are everything that could possibly be required for the purposes intended.

The value of coal for such a purpose depends upon the absence of sulphur, and as no coal has been discovered which is absolutely free from that element it is its comparative absence or presence that must be taken as a criterion. The Raneegunge coal, compared with that used at the best pottery works in England, contains an excess of sulphur; this for unglazed work is a matter of no moment, and for glazed work the specimens of the work have only to be seen to lead to the conclusion that sulphur is not present in sufficient quantity to interfere with the value of the coal as a heating agent, even where glaze is employed. The company has now on hand as much work as it can manage to execute; it manufactures roofing and flooring tiles (glazed, and vitrified), drainage pipes, water-pipes, firebricks, telegraph insulators, and any description of pottery work. Several articles of household use—jugs, serais, &c.—have been made experimentally, and the success is such as to prove that the only necessary which is wanting to enable the company to carry on a large business, even in that small branch of their manufacture, is the want of competent workmen. For these the company must depend principally upon the Government School of Art in Calcutta; but even the men turned out from this institution require a great deal of practice and further instruction before they can be called skilled workman.

The encouragement of local industry and local trade is in all cases desirable as a matter of policy; but when that industry supplies articles as well suited for the purposes intended as any that can be procured in England or elsewhere, there can be no doubt that, as this company and it manufactures come to be better known, their difficulty will be to keep the supply equal to the demand that is sure to arise for some, if not all, of the articles they manufacture. We wish them every success, and hope, at some future time, to have an opportunity of visiting their works, and giving our readers a full description of the various clays found at Raneegunge, and an account of the mode of manufacture adopted by their manager. The proverbial cleanliness of the Dutch is owing chiefly to the fact that their rooms are floored, and partly panelled, with small glazed tiles which can be thoroughly washed daily, and become perfectly dry in a few minutes. We cannot conceive a greater luxury in this climate than having rooms that can be so cleansed instead of being compelled to endure the dust and vermin that collect in the mats which we are at present obliged to use. To natives, whose forms of religion require that their apartments should be purified by the use of water, such floors would be invaluable.

DOUBLE CYLINDER STEAM-HAMMER.

MESSRS. THWAITES AND CARBUTT, of Bradford, have perfected two novel forms of steam-hammer, one of which is illustrated on the other side. Under the new system the weight of the standards and pistons in one case, and standards and cylinders in the other, are made available in striking the blow. In the first case the cylinders are fixed in the ground, and the pistons connected by a powerful crosshead, carrying the hammer between them; in the second, the pistons are fixed to the foundation, and the cylinders move, having the hammer-block incorporated with them. In the case of the stationary cylinders the steam is admitted by the same valve to both, the distance which it has to travel being, of course, exactly equal for both cylinders. In the machine in which the pistons stand, and the cylinders move, the valve levers are connected by a rod, so that they must move simultaneously. The difficulty of obtaining this simultaneous motion has been urged against the system, but Messrs. Thwaites and Carbutt have had so much experience in making the valve machinery for Mr. Ramsbottom's duplex hammer act together, that they are confident of success. If successful, the plan will effect a great saving in the weight

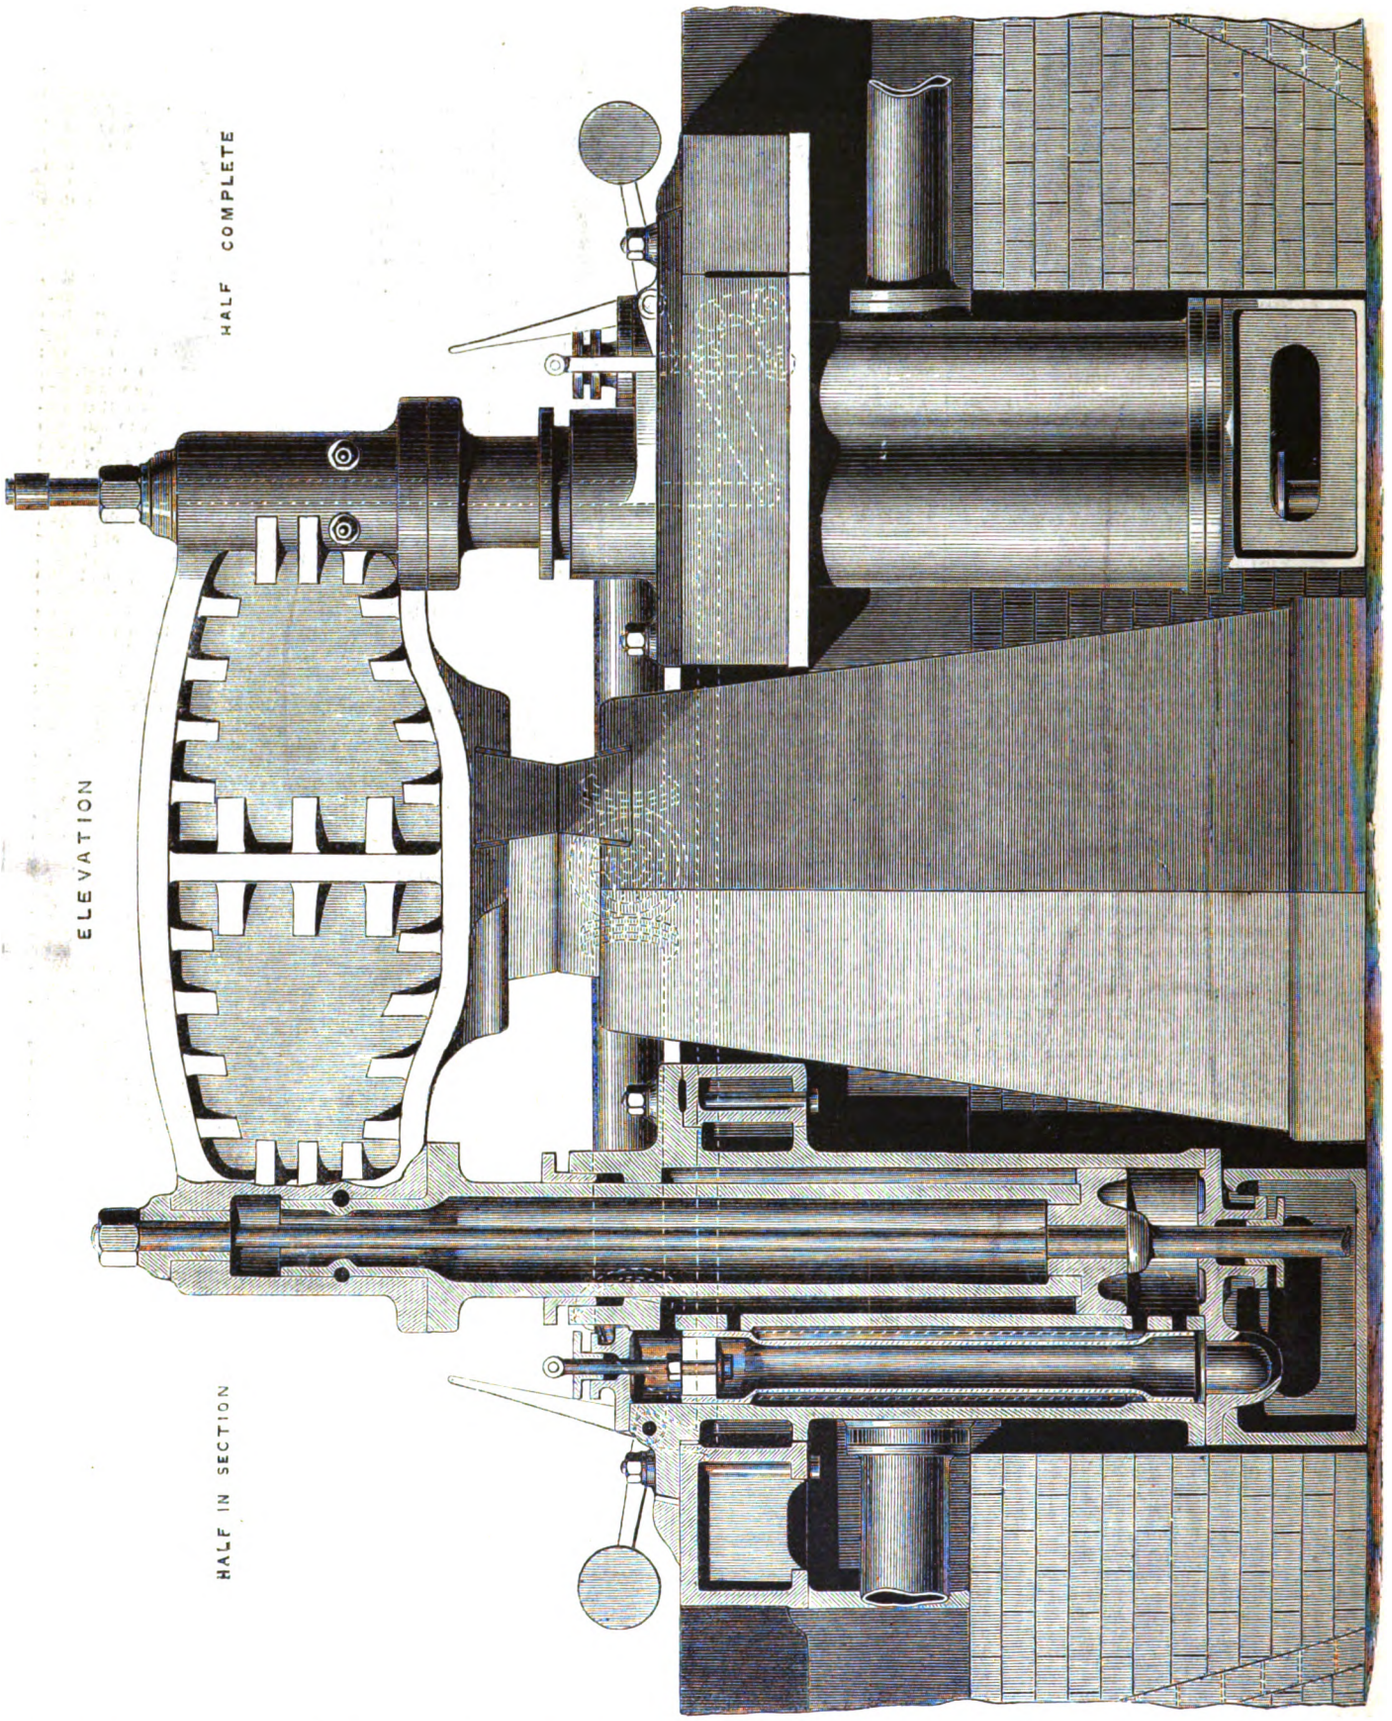
DOUBLE-CYLINDER STEAM HAMMER.

BY MESSRS. THWAITES AND CARBUTT.



of the heavier class of hammers, and also in the height and ground space they will occupy. A 25-ton hammer requires a building upwards of 35ft. high, and its two standards weigh, perhaps, 25 tons each. In Messrs. Carbutt's system it will easily be seen that much of this size and weight can be dispensed with. The hammer we illustrate has two fixed cylinders, arranged at the angles of a heavy anvil block disposed equi-distantly between them. The pistons have differential areas, as the greatest force is, of course, required to raise the tup, or hammer. The rods pass through the bottoms of the cylinders, and the crosshead is so massive that no distortion or twisting can take place; indeed, the only course for such twisting would lie in a variation in the friction of the pistons and stuffing-boxes, which must be very small. The valves are cylindrical, and balanced. They are worked either by hand, or by means of a tappet rod connected with the left-hand piston-rod and cam gear, shown by dotted lines.

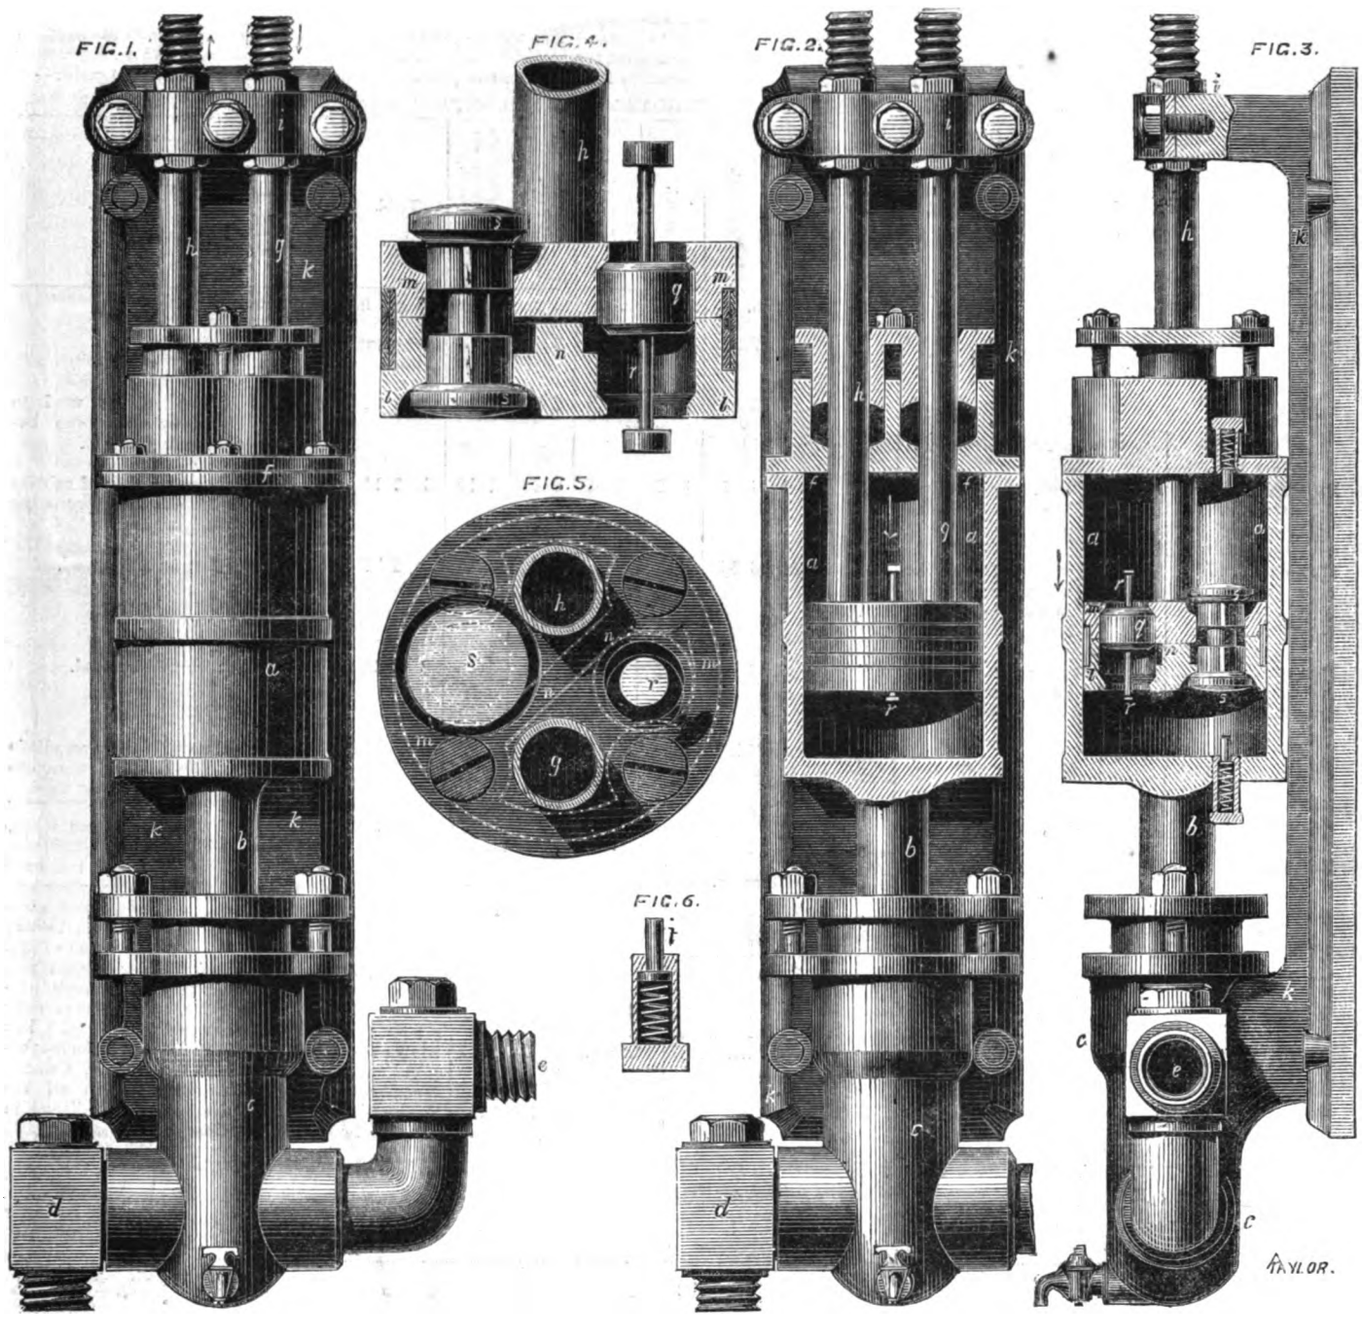
DIRECT-ACTION DONKEY PUMP.

BY MESSRS. WAYGOOD AND CO.



DIRECT-ACTION DONKEY PUMP.

THERE has been much discussion of late on the subject of donkey pumps. Whatever the merits or demerits of those in general use may be, there can be no question of the value of the one illustrated in the accompanying engraving. It is the patented invention of the proprietors of Waygood's Newington Ironworks, Brunswick-street, Dover-road, London, where we inspected one at work, and a number in course of manufacture. The pump certainly works most efficiently, and although but recently perfected is deservedly gaining favour with engineers, and has been adopted by the Government. Referring to our engraving, which represents one of these donkey engines, fig. 1 is a front elevation; fig. 2 is the same elevation with the cylinders in section; fig. 3 is a side elevation with the cylinder and piston in section; figs. 4 and 5 are respectively a vertical section, and a plan of the piston on a larger scale. *a* is the cylinder which has no inlet or outlet ports. *b* is the plunger or bucket rod which is attached to the lower end of the cylinder *a*. *c* is the pump barrel, *d* the suction pipe, and *e* the outlet or force pipe. The upper end of the cylinder *a* is provided with a cover *f*, through which two pipes *g h* are passed; the pipe *g* acts as the supply pipe, and the pipe *h* as the exhaust pipe for the steam or other motive fluid. These pipes *g h* are connected at their upper end to a fixed crosshead *i* forming part of the framing *k*, while the lower ends of the pipes are attached to the cover of the piston. The pipes *g h* serve as guide rods for the movements of the cylinder *a*. The piston is composed of two parts, the body *l* and the cover *m*; the body *l* is hollowed out on the upper side, and has a partition *n* which divides the hollowed-out portion into two chambers *p*, in which the pipes *g h* terminate. The piston body and cover *l* and *m* have each two apertures in which valves are free to move. One of these valves *q* is the inlet valve, and has two opposite faces to take the seats on the interior of the piston; it has two pins *r r* projecting from it which are acted upon by the respective ends of the cylinder *a* at the completion of each stroke, whereby this valve is shifted. The other valve is the exhaust valve, and is composed of two puppet valves *s s* made in one piece so as to act in two directions. The opposite faces of this valve work on seats on the outside of the piston. On the completion of each stroke the double valve *s s* is closed by a spring pin *t* in the cylinder end and the other valve *s* opened for the exhaust in the return stroke. Fig. 6 is a section on a larger scale, showing one of the spring pins *t*. The pressure of the steam on the surface of the piston on either side keeps the valve *s s* upon its seat during the movement of the cylinder *a* in either direction. The simplicity and efficiency of this apparatus induce us to recommend our engineering friends to give it a trial. Mr. Waygood exhibited one of these pumps at the conversazione of the Institution of Civil Engineers on Tuesday evening, where it attracted considerable notice, and was greatly approved of.

THE display of fireworks at the Crystal Palace, on Monday evening last, was the most brilliant ever witnessed there. Whether we take the beauty of the colours, the elegance of the designs, or the extensive character of the display, we can but pronounce it a triumph of pyrotechnic art. We advise our readers not to miss the next opportunity of witnessing the magnificent effects produced, which the mingling of the fountains render the most striking and remarkable ever seen.

ON CERTAIN POINTS IN THE MANUFACTURE OF MALLEABLE IRON, WITH SPECIAL REFERENCE TO THE RICHARDSON PROCESS.*

By Mr. St. John Vincent Day, C.E.

(Continued from page 389).

HAVING now shown the general nature of previous attempts, I proceed to explain the different course of action that Mr. Richardson adopts. In place of continuous blowing the blast is introduced through a tubular rabble connected with a blast receiver immediately after the charge is melted, and continued until the metal is brought to "the boil," when it is withdrawn. The period from the melting to the boil with the iron used at Parkhead under the common method of puddling occupies from 25min. to 40min.; this by the Richardson process, is reduced to 10min. The temperature of the furnace being higher, the period from the commencement of the boil to that when decarburization and desilicatization are completed, and the iron separates from the slag and cinder, is again reduced. But the balling operation is of a little longer duration than under the old method on account also of the greater temperature, the granules of iron requiring more time to cool down to that temperature at which they adhere when pressed together. The following table, No. 1, of some of the first experiments made at the Glasgow Ironworks shows the time occupied in conducting each stage of the process, as well as the yield:—

Table No. I.—EXPERIMENTS AT THE GLASGOW IRON COMPANY'S WORKS.

Date of Experiment, and Number of Furnace.	Weight of Charge.	Charge composed of.	Time of Charging.	Iron melted at.	Blast put in at.	Blast on till.	First Ball out.	Last Ball out.	Time occupied from charging until the Iron was fined.	Yield.	Diminution of Charge.	Remarks.
	cwt. lbs.		h. m.	h. m.	h. m.	h. m.	h. m.	h. m.	h. m.	cwt. qrs. lbs	cwt. qrs. lbs.	
May 30, 1867. Furnace No. 17 ...	4 0	Pig iron exclusively...	7 0	7 27	7 28	7 36	8 4	8 8	1 8	Not ascertained.	Not ascertained.	
June 11. Furnace No. 17 ...	4 0	Pig iron exclusively...	6 12	6 42	6 43	6 47	7 18	7 22	1 10	3 3 14	0 0 14	Three rabbles used to prevent any one becoming too hot.
June 11. Furnace No. 17 ... Refettled.	4 0	3 cwt. pig iron and 1 cwt. refined or plate-metal.	7 30	8 1	8 1·5	8 6·5	8 35	8 40	1 10	3 2 14	0 1 14	Same number of rabbles used as in the preceding experiment.
June 13. Furnace No. 17 ...	4 0	Common pig of the worst quality used in the works for a long time.	6 5	6 35	6 35	6 43	7 16	7 20	1 15	3 2 7	0 1 21	Three rabbles used.
June 13. Furnace No. 17 ... Furnace refettled, and again charged.	4 0	Same as in the preceding experiment.	7 30	8 3	8 4	8 12	8 36	8 41	1 15	3 3 18	0 0 10	Five rabbles used.
Means	4 0		Mean time of blowing in 6·36 minutes ...						1 11	3 2 27·25	0 1 0·75	The rabbles are very little affected, and therefore will last a long time.

In these experiments the time of working a charge composed entirely of Scotch pig was brought down to 1hr. 8min. whereas the usual time is from 1hr. 30min. to 1hr. 45min. under the old method; the yield is considerably higher; so high, indeed, as to require only 21cwt. 1qr. 17lb. of pig iron to produce a ton of malleable iron, showing a loss on the conversion of only about six per cent. Then as to the purity of the iron, it is most remarkable; two samples which I sent to Dr. Stevenson Macadam, of Edinburgh, to be analysed have given the following results:—

Analysis.

Name of Element.	Square Bar.	Round Bar.
Iron	99·569	99·648
Carbon	0·035	0·031
Silicon	0·076	0·075
Sulphur	0·025	0·028
Phosphorus	0·031	0·034
Manganese	Trace.	Trace.
	99·736	99·816

We see the sulphur and phosphorus are withi, the merest shadow of being entirely eliminated evidently showing that some special influence must be present when puddling iron according to Richardson's system that is not found elsewhere; iron never has been made from British ores, on a commercial scale, so pure as in these two instances. Made from inferior Scotch pig, which always contains such a very large percentage of these two elements, the extent of their elimination is all the more remarkable. But not to draw any hasty conclusions, I have prepared tables Nos. 2, 3, 4, 5, 6, 7, and 8, showing the percentages of these elements in all the British pig irons, from the analysis published in the Blue Book "On Cast-iron Experiments."

Table II.—HÆMATITES. SULPHUR AND PHOSPHORUS COMBINED IN PIG IRON MADE IN WHITEHAVEN AND ULVERSTONE DISTRICTS FROM HÆMATITE ORES.

Particulars as to the Ores from which the Pig Iron was made.	Sulphur per cent.	Means of Sulphur.	Phosphorus per cent.	Means of Phosphorus.	Remarks.

The only analysis of pig iron from North Staffordshire that I possess contains the very high proportion of 1·07 of phosphorus, and 0·04 of sulphur.

It is a very remarkable fact that I have not been able to obtain many reliable analysis of black band pig iron, or indeed of the other Scottish irons that are guaranteed by authority; this is not only a peculiarly striking fact, it is moreover one to be greatly deplored. It is true that I am in possession of several analyses in which phosphorus does not present itself at all; this certainly is notorious, as it is well known that the black band pig irons do contain a very large percentage of phosphorus, and I can therefore only suppose that this element, always most difficult of detection, has not been carefully sought for. The paucity of analyses in this respect is no doubt principally due to the fact that so much of the Scotch pig iron is used and exported from the country as "foundry iron." Now it is perfectly evident that for foundry purposes the presence of phosphorus is of considerably less importance than would result if the pigs were so largely used for making malleable iron as the English, Welsh, and Continental ores. It being certain that the presence of phosphorus has so much to do with the tensile strength of malleable iron, this, no doubt, has been the chief incentive to the undertaking so many careful analyses of those pig irons from which malleable iron is principally made, in order that to produce the highest quality of finished iron, ores containing the least amount of phosphorus might be selected.

(To be continued.)

Legal Intelligence.

VICE-CHANCELLOR'S COURT.

May 26.

(Before Vice-Chancellor GIFFARD.)

THE ATTORNEY GENERAL *v.* LEONARD EDMUNDS.

ON Tuesday last, this celebrated case, best known to our readers as the Edmunds scandal, was opened by the Attorney-General, Sir J. B. Karslake. It will be remembered that the information which was filed on the part of Sir R. Palmer, when Attorney-General, asks that an account may be taken of all fees and moneys received by the defendant as Clerk of the Patents and as Clerk of the Commissioners of Patents since the date of his appointment, and also of all moneys received by him from the Lords of the Treasury for the expenses of Clerk of the Commissioners of Patents, and of the application by the defendant of all such fees and moneys respectively. It further asks that it may be declared that in taking such accounts the defendant ought to account for all profits made by the purchase and resale of stamps, and that he is not entitled to make any deduction whatever for or in respect of the parchment used in the preparation or engrossment of any document issued by him as Clerk of the Patents, or from the office of the Clerk of the Patents, or any other deduction in respect of the preparation of any such document; and that the defendant may be ordered to pay what may be found due from him, with interest on the balances in his hands from time to time.

The defendant, in his answer, submitted that the Court of Exchequer was the proper court to try this case; but, as he was anxious to meet the charges affecting his character contained in the information, he made his answer without prejudice to his right to demur to the information. So far from offering any objection to the taking of the accounts prayed for by the information, he was most anxious that they should be taken, provided that they should be taken in a just and equitable manner, and that all just and due allowances were made to him, having regard to the circumstances in which he was placed, and also to the true intent of the several Acts of Parliament under which he held the aforesaid appointments; and he was advised, and believed, that, instead of being indebted to the Crown, he was fairly entitled to receive from the Exchequer (independent of the amount due to him in respect of discount for stamps) the sum of £7,715 17s. 11d., and from the Suitors' Fee Fund the sum of £130 17s. 2d., amounting together to £7,846 15s. 1d.

The Attorney-General contended that the defendant, since 1844, had made deductions which were not justified by the Acts of Parliament, and that, as, by means of money belonging to the Crown, he for a long series of years made large profits by purchasing from the Crown stamps at prices lower than those at which he sold them to the persons to whom he issued patents, he must account for that profit.

Sir R. Palmer, who followed on the same side, said the defendant in his answer distinctly admitted that, as an accountant to the Crown, he for a long series of years received sums for which he had not regularly given any account, in consequence of circumstances preventing him from doing so. There could be no doubt that, for the purpose of taking accounts such as these, this court had as complete jurisdiction as the Court of Exchequer. The defendant, on the ground that the expenses of his office were too great in comparison with his salary, undertook to make alterations in the practice of the office in his own favour, alterations which were in direct contravention of the Act of Parliament. No employé, without the consent of the employer, could be justified in taking such a course as that.

At this stage of the proceedings the court adjourned, and on resuming its sitting on Wednesday, Mr. Digby Seymour, Q.C., on behalf of Mr. Edmunds, contended that, according to the evidence of the officials in the public departments, he was entitled to invest the balances of public money in his hands in any way that he might think most profitable, and that the profit accruing from such investment belonged to him. The only duty that devolved upon Mr. Edmunds with regard to these balances was that when he was called upon to account for them he should be ready to do so. It was a most tyrannical proceeding on the part of the Crown now to call upon Mr. Edmunds to account for matters extending over a period of thirty years. If, instead of filing this information, the Crown had preferred an indictment charging him with having wilfully misappropriated money, the verdict of the jury would have been speedily pronounced. But the present proceeding was worse than an indictment. When could the accounts which were asked for be completed? They might as well open the floor of the court and bury him 100ft. deep, as subject him to the long torture of taking accounts extending over a period of thirty years. Mr. Edmunds had groaned over the long delay that had already taken place in the investigation of this affair. What new light could be gained by referring these accounts to chambers? Already a sort of Star Chamber inquiry, from which the gaze of the public eye was excluded, had been carried on against him. In the name of justice he (Mr. Seymour) protested against the tyrannical proceedings which the Crown had adopted against Mr. Edmunds, and in using that emphatic language he was ready with all his heart and soul to accept the consequences of it.

The case is still proceeding, and we shall resume our report next week.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 8d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

ERRATUM.—In an article on "Testing and Annealing Steel Plates," which appeared in our issue of the 15th inst., occur the following words:—"The following is a remarkable illustration of the superiority of the system of drilling holes in *armour* plates to that of punching them." The word "armour" should be "steel."

Meetings for the Week.

MON.—Royal United Service Institution.—Mr. J. R. Hamilton, late C S. Navy, on "The American Navy: its Organization, Ships, Armament, and Recent Experiences," at 8.30 p.m.

Royal Institution.—General Monthly Meeting, at 2 p.m.

TUES.—Royal Institution.—Dr. M. Foster on "The Development of Animals," at 3 p.m.

THURS. — Royal Institution.—Sir J. Lubbock on "Savages," at 3 p.m.

FRI.—Royal Institution.—Sir S. Baker on "Abyssinia," at 8 p.m.

Royal United Service Institution.—Colonel H. Lane Fox, late Grenadier Guards, on "Primitive Warfare, Section 2. On the Resemblance of the Weapons of Early Races: their Variations, Continuity, and Development of Form," at 3 p.m.

SAT.—Royal Institution.—Sir J. Lubbock on "Savages," at 3 p.m.

Naval, Military, and Gunnery Items.

DURING the past week 31 wrecks have been reported, making for the present year a total of 925.

WE hear that General Sir Duncan Cameron has accepted the post of Governor of the Military College at Sandhurst.

WE understand that the volunteer review proposed to be held in Windsor Park, on Whit-Monday, has been finally abandoned, owing to her Majesty's intention to review the volunteers later in June.

IT is announced in Ottawa, Canada, that the English Government have agreed to fix the tax on American vessels fishing in Canadian waters at two dollars a ton, and dispense with the three warnings heretofore given to such vessels.

THE "Moniteur de l'Armee" publishes a report from Marshal Niel, dated the 20th inst., confirming the excellence of the Chassepot rifle, and stating that its incomparable qualities assure to it the first rank among the arms of war now employed. The report adds that the whole of the French infantry are now armed with the Chassepot. The manufacture is actively carried on; the mean daily number turned out last week was 1,600.

ACCORDING to the "Bureau Veritas" of Paris, the number of vessels reported as totally lost during the month of April was 202, including 93 English, 27 American, 19 French, 15 German, 9 Norwegian, 6 Dutch, and 33 bearing various other flags. The number of total losses during the first four months of the present year was 883, which, as compared with the corresponding period of 1867, shows a diminution of 284 in the list of such disasters.

A LETTER from Toulon, quoted by the "Temps," says that the ironclad monitor "Rochambeau," brought from the United States, will not cost more than ten millions of francs (£400,000), all reparations included. It is said that it is a splendid instrument of war, but that it leaks like a sieve—as much as 100 tons of water in twenty-four hours. This, it is stated, does not arise from any bad construction, but from the bad quality of the wood, which is half rotten.

THE docks are being prepared at Chatham for laying down the keels of two new powerful ironclad ships which are ordered to be constructed at that

Digitized by Google

establishment. The "Triumph" and the "Sultan," the two vessels, will be of the broadside class, of the "Hercules" type, the "Sultan" being the most powerful of the two, both for offensive and defensive purposes, her armour-plating being 9in. in thickness, while that of the "Triumph" will be of a maximum thickness of 8in. The "Triumph" is to have her bottom sheathed with wood, overlaid with copper.

WIMBLEDON meeting, next July, will be distinguished by some new features. Not less than £10,125 will be distributed in prizes to the competitors. On former occasions the money would have been divided among the Volunteers only, but this year, by a happy innovation, it has been determined to summon picked infantry soldiers of the regular army to Wimbledon, and reward the successful for their skill. Not only are there money prizes for individual men given by the Association but there is in addition a challenge shield, which will be held by the regiment whose marksmen may win it.

THE pensions for distinguished or meritorious service, vacant by the appointment of Generals Horn, Longfield, and Gratten to regimental colonelcies, have been given to Colonels K. D. Mackenzie, Deputy Adjutant-General in Ireland, Robert Pratt, 23rd Fusiliers, and R. J. Eagar, 31st Regiment. These rewards are well deserved. The "Army and Navy Gazette" states that Colonel Mackenzie has been 37 years in the army, and served with great ability on the Staff in the Crimea, and in China in 1860. Colonel Pratt has been in the army since 1837, was with the 41st in the Afghan Campaign of 1842, in the Crimea, and in the Indian mutiny in 1858 and 1859. Colonel Eagar's first commission bears date 1830, and his services also comprise the Afghan and Crimean campaigns.

Miscellanea.

A SYCAMORE tree 110ft. high, with a hollow 14ft. in the clear, is reported to be standing in Calhoun county, Illinois.

ALL the diamond cutting in America is done by one firm in Boston, and their business is confined to the re-cutting of stones which have been nicked or otherwise rendered imperfect.

WE remind our readers of the treat at the Horticultural Gardens, South Kensington, in the great flower show, which takes place on Tuesday, and the three following days of next week.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending May 23, was 2,396; total number since the opening of the museum, free daily (May 12, 1858), 1,300,543.

INTELLIGENCE from Newfoundland received at St. John's on the 8th says that the seal fishery has been, on the whole, successful up to the 28th ult. Two hundred and fifty thousand seals had arrived at St. John and Harbour Grace.

DURING the month of March twelve ships, with 1,066 emigrants, sailed from Genoa for South America. Of this number 267 were natives of Genoa; 150 of Sondrio; 118 of Como; 96 of Milan; 59 of Potenza; 45 of Cuneo; 44 of Turin; 36 of Alessandria; 29 of Salerno; and 27 of Pavia.

THE shock of earthquake at Tachkent, on the 5th inst., lasted nearly a minute, the direction being from south-west to north-east. All the buildings were shaken, and most of them seriously damaged. Nine men, four women, and two children were killed by the fall of houses, and six other persons slightly injured.

THE Supreme King of Siam has published an official list, with the names of his children, the dates of their birth, and of the dates of those deceased. The whole number is 81, of whom the eldest was born in 1823, the youngest in 1868. Sixty-six are now living. The late Second King had 63 children, of whom 30 are now living.

ONE of the most important products in Italy is olive oil. The average annual production is upwards of 1,500,000 hectolitres (33,000,000 gallons), representing the value of about 200,000,000f. (£8,000,000 sterling). A large amount is consumed in the country, and the exports do not exceed 70,000,000f. (£2,800,000).

A SUCCESSFUL attempt at growing opium has been made in Victoria. A few plants have been raised this year, and the produce has been pronounced by good judges to be of first-rate quality. The Chinese horticulturists in those districts will no doubt avail themselves of this experience, and it is expected that opium crops will be largely cultivated.

WE are glad to inform our readers that a number of Mr. Dobson's mules for spinning and doubling, one of which we described and illustrated last week, are at work, and are giving very satisfactory results. They spin equally well the highest or the lowest number of cotton or wool, and can work with single speed for coarse or double speed, for fine numbers, as may be required.

AT the South Kensington Museum the visitors during the week ending May 23, 1868, were on Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 7,740; on Wednesday, Thursday, and Friday (admission, 6d.), from 10 a.m. till 6 p.m. 1,678. National Portrait Exhibition, by payment, 2,359; total, 11,786. Average of corresponding week in former years, 9,673. Total from the opening of the museum, 7,397,969.

THE experimental trains over Mont Cenis, ordered by the French and Italian Governments, have worked daily with great regularity and success. The Duke of Sutherland, Messrs. Brassey, Blount, Buddicom, Brogden, and Fell, directors; Mr. Brunlees, engineer; Count Arrivabene, a member of the Italian Parliament, and about fifty more, travelled over the line on the 22nd and 23rd inst. The opening for public traffic is fixed for June 8.

AT a meeting of the Fellows of the Royal Botanic Society, on Saturday, Lord Tredegar in the chair, the names of the following candidates for the fellowship were read:—Sir Lionel Darell, Bart., Julian Goldsmid, Esq., M.P., Captain W. E. P. O'Brien, Mrs. Van Raalte, Miss Cancellor, John Walker Anderson, Esq., Henry H. Temple, Esq., R. P. Wilson, Esq., Cyril M. M. Rawlings, Esq., Mrs. George Burleigh, Miss Harvey, Richard H. Barnes, Esq. Mrs. Cornmell, Thomas O. Hutton, Esq., Mrs. Cook, Mrs. Chase, Miss Arbonni, and Lieutenant-Colonel, Revell, in addition to seven elected on the same day.

THE "Daily Telegraph" of this week has borrowed, without acknowledgment, some of our thunder. Last week, in an article on the "Silver Coinage of Great Britain," we demonstrated that the whole of the shillings, sixpences, and subordinate silver coins of this country of a date anterior to that of the accession of Queen Victoria, ought to be re-cast and re-coined. The "Daily Telegraph" of yesterday, evidently acting upon the inspiration of the MECHANICS' MAGAZINE, virtually recommends a similar course, and borrows some of its identical expressions. It does not, however, acknowledge the source of inspiration.

WITH much pleasure we announce that the Council of the Society of Arts have this year awarded the Albert gold medal to Mr. Joseph Whitworth "for the invention and manufacture of instruments of measurement and uniform standards by which the production of machinery has been brought to a degree of perfection hitherto unapproached, to the advancement of arts, manufactures, and commerce." The medal was instituted to reward "distinguished merit in promoting arts, manufactures, or commerce," and among the recipients in former years have been Sir Rowland Hill, Professor Faraday, and Messrs. Cooke and Wheatstone.

THE Directors of the Metropolitan Railway have made an inspection of the works in progress on the extension of that line between Paddington and Gloucester-road, Kensington. They were accompanied by Lord Gort, and other directors of the Metropolitan District Railway; the contractors, Messrs. Kelk, Waring, Brothers, and Lucas; the engineers, Messrs. Fowler and Johnson, and by other officers of the company. The whole of the works were found to be in an advanced state, and it is confidently hoped that in the course of the summer this very important link of the inner circle of the Metropolitan Railways will be opened for public traffic.

AT the meeting of the Metropolitan Board of Works a report was presented on the proposals of the Metropolitan District Railway as to the construction of their line between the Temple and Blackfriars Bridge. A provisional agreement had been entered into for the construction of a solid embankment with a 100ft. roadway thereon from the Temple-gardens to Blackfriars Bridge, and the company to construct their railway within the embankment; the railway company to commence their works for the construction of the railway on the embankment from Westminster Bridge to the Temple on July 1 next, and the other works to be carried on simultaneously with the works of the board; the railway company to deposit £10,000 on July 1 next; the payment of the £200,000 to be paid to the board to be spread over three years. The report was adopted.

A MIRAGE was strikingly conspicuous on Sunday afternoon and evening at Dover. The "Dover Chronicle" states that the dome of the Cathedral and Napoleon's Pillar at Boulogne were to be seen from the Crescent Walk by the naked eye, but with a telescope of ordinary power, the entrance of the port, its lighthouse, its shipping, and the surrounding houses, the valley of the hillside of Capecure, and the little fishing village of Portel, were distinctly visible; whilst on the eastern side the principal features of the country, the lighthouse of Cape-Grinez, the adjacent windmill, numerous farms and villages, with their windows illuminated by the setting sun, stood out with extraordinary clearness. Whilst these were under observation, a locomotive was seen to leave Boulogne, and travel some miles in the Calais direction by its puffs and wreaths of white steam. Shortly after sunset the mirage subsided.

MR. E. D. YOUNG, a friend and companion of Dr. Livingstone, has been lecturing at Long Sutton, Lincolnshire, on the course probably taken that distinguished traveller. When an expedition in search of Dr. Livingstone was determined on, Mr. Young was consulted on the subject; his plans were approved, and he was entrusted with the command. The expedition left England in June, 1867. Mr. Young found traces of Dr. Livingstone, but was compelled to return to the mouth of the Zambesi again in December. In speaking at Long Sutton, Mr. Young pointed out the route probably taken by Dr. Livingstone, viz., along Lake Nyassa, and thence by Lake Tanganyika, of which only the southern and northern ends are explored, leaving the immense middle undetermined. Mr. Young expressed his opinion that it would be found one wonderful lake, and the real source of the Nile. He added his belief that Dr. Livingstone would take Speke's and Grant's, or a similar route, and return through Egypt.

THE foundation stone of Her Majesty's Theatre has just been exhumed. Upon its being raised, in a cavity in the bed of the stone, were found a guinea, date 1788; half-guinea, date 1789; a shilling, date 1787; a sixpence, date 1787; a fourpenny-piece, date 1786; a threepenny-piece, date 1772; a twopenny-piece, date 1786; and a silver penny-piece, date 1786. The position of the stone was in the north wall of the box corridor, on the centre line of the auditorium, under the opening leading from the hall to the pit corridor, at a depth of 2ft. 3in. below the paving of the hall. The dimensions of the stone are 2ft. 1in. long, 1ft. 1½in. wide, and 1ft. deep. The inscriptions on the stone are as follows:—On the top, "The first stone of this new theatre was laid on the 3rd of April, 1790, in the 30th year of the reign of King George III., by the Right Hon. John Hobart, Earl of Buckingham—*Auctor pretiosa facit.*" On the front—"The King's Theatre, in the Haymarket, first built in 1703." At the right end—"But unfortunately destroyed by fire on the 17th of June, 1789." On the back—"*Prevalebit justitia.*"

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3179, 3180, 3200, 3212, 3245
BUILDINGS AND BUILDING MATERIALS—3206, 3220, 3234
CHEMISTRY AND PHOTOGRAPHY—3191, 3217, 3232
CULTIVATION OF THE SOIL, including agricultural implements and machines—3199
ELECTRICAL APPARATUS—None.
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3173, 3177, 3190, 3227, 3236, 3242, 3249
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—3182
GENERAL MACHINERY—3174, 3176, 3183, 3186, 3194, 3196, 3203, 3208, 3228, 3230, 3237, 3246
LIGHTING, HEATING, AND VENTILATING—3171, 3172, 3181, 3194, 3198, 3208, 3209
METALS, including apparatus for their manufacture—3205, 3226, 3248
MISCELLANEOUS—3175, 3188, 3193, 3195, 3197, 3201, 3202, 3204, 3207, 3210, 3213, 3215, 3222, 3224, 3225, 3229, 3233, 3235, 3238, 3239, 3240, 3244, 3250
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—3178, 3223
SHIPS AND BOATS, including their fittings—3231, 3247
STEAM ENGINES—3219, 3221
WARFARE—3185, 3187, 3189, 3211, 3214, 3216, 3241

3171 M. ROLLASON. *Improvements in suspended gas lamps* Dated November 9, 1867.

The patentee claims the improvements described and illustrated in the drawings in raising and lowering the lower part of the globes or shades of suspended gas lamps, that is to say, by means of a rod or tube connected with the ring of the upper or fixed part of the globe or shade, the said sliding rod or tube being supported in the fixed tube either by springs or by a stuffing box, and fixed, when in its raised position, by a bayonet joint fastening, substantially as described and illustrated.—Patent completed

3172 T. W. INGRAM and E. C. KEMP. *Improvements in gas lamps.* Dated November 9, 1867.

The patentee claims making the suspended chains of the lower half of the globe or shade of the lamps work in a frame of tubes, substantially as described. Suspending the globes or shades, made in one piece, of the said lamps by hooking or engaging the ends of the suspending rods to the said globes or shades, or to a gallery supporting the said globes or shades, substantially as described. Supporting and adjusting the height of the smoke condensers or smoke tops by means of a screwed rod taking into a screw in a tripod, resting on the top of the shade or globe, substantially as described and illustrated; also making the tripod capable of expanding and contracting to fit shades or globes having different size openings at top, substantially as described.—Patent completed.

Digitized by Google

3173 C. BEDELLS. *Improvements in the manufacture of elastic fabrics, part of which invention is especially applicable to the production of shaped slipper fronts and similar articles.* Dated November 9, 1867.

The patentee claims the manufacture of elastic fabrics by cementing cords or tapes of vulcanized india-rubber in an unstretched state between two pieces of looped fabric, distended in the direction opposite to that in which the elasticity is required, and in which the india-rubber cords or tapes run. He also claims the manufacture of slipper fronts and similar articles in the manner described.—Patent completed.

3174 G. FARREN. *Improvements in apparatus for taking and registering votes in deliberative assemblies.* Dated November 9, 1867.

For this purpose the inventor provides each seat in the chamber with two finger keys, an aye and a no; by moving these keys electric circuits are made or broken. In this way each finger key when moved gives motion to a lever or instrument, of which there are a series arranged in a glass or other case in front of the chairman, or in other convenient position. The movement of each lever or instrument liberates a small weight, which, by a conducting channel, is led into the scale pan of a balance. There are two such balances provided, one for the ayes, the other for the noes; they should be enclosed in a glass case. By weighing, the number of weights in the pan is immediately ascertained, and the balances should be so arranged as to indicate this number visibly; a delicately-made spring balance is suitable. The apparatus is furnished with a handle or other instrument, by means of which the chairman or other person can keep the finger keys at the members' seats out of action, until the moment when it is desired to take the votes. The levers or instruments corresponding with the finger keys in front of the members' seats also carry pencils or markers, so that when they move they record the vote on a list suitably placed in relation to the series of pencils or markers. When one finger key has been moved, the other key belonging to the same seat is inoperative.—Patent abandoned.

3175 G. F. PARRATT. *Improvements in the manufacture of flexible air-tight cylinders or cases to be used as pontoons and in forming rafts.* Dated November 9, 1867.

According to this invention, the inventor protects flexible air-tight cylinders or vessels so as to render them very durable by cementing over them a strong case of closely-woven fabric, and then painting with a rapidly-drying paint over the surface of the case so applied.—Patent abandoned.

3176 W. LAWRIE. *Improvements in apparatus for burning mineral oils or other hydrocarbons to obtain heat therefrom.* Dated November 9, 1867.

For this purpose the mineral oil or other hydrocarbon to be burnt is placed in a tank, in the interior of which is a coil of pipe, through which steam is passed, in order to keep the hydrocarbon in a sufficiently fluid state. Near the bottom of the tank is a tap by which the oil or liquid passes away to be burnt, and the amount so passing away can be regulated by means of the tap. The oil or liquid passing out by the tap is received into a pipe, which conducts it into a closed retort, one end of the steam pipe being led from the tank near to the tap above mentioned, and is led down the interior of the pipe which conducts the oil to the retort, and just before this pipe enters the retort the end of the steam pipe is taken out through its side, and this end of the steam pipe is left open so that the steam may escape from it. The hydrocarbon in the pipe is thus kept in a sufficiently fluid state. The pipe leading into the retort passes in at its front end and is led along nearly to the back, and the oil or liquid passes into the retort from this end of the pipe. Below the retort, and extending back beyond it, are burners at which the vapours or gases produced in the retort are burnt, and the retort is thus kept heated, pummice stone, or other rough material, being placed over the bottom of the retort, so as to fill it up to the level of the oil pipe, and present a considerable extent of heated surface to the vapours formed from the hydrocarbon.—Patent abandoned.

3177 J. H. W. and A. W. BIGGS. *Improvements in joining warp ends, and in apparatus employed therein.* Dated November 9, 1867.

Heretofore, when a warp has been woven up in the loom, it has been usual to twist or knot the ends of the old threads on to the ends of a new warp. This operation has been, up to the present time, performed thread by thread by hand. According to this invention this operation is performed by the aid of machinery; the ends of the two warps, or of portions of the warps, are distended on a frame, and the ends which are to be joined are approximated each to each, and twisting, knotting, or cementing instruments spin, tie, or cement them together in pairs, simultaneously or in succession. Similar means and apparatus are applicable in joining warp ends in the dressing operation, when the warp threads are wound off beams or rollers, dressed, and then wound on to the warp beam, when the beams or rollers from which the warp threads are drawn become empty, the ends of threads on other beams or rollers are joined up to them.—Patent completed.

3178 W. THOMPSON. *Improvements in omnibuses and similar vehicles, and in apparatus in connection therewith, parts of which improvements are also applicable to railway and other carriages.* Dated November 11, 1867.

The patentee claims, first, the application to omnibuses and vehicles of a similar character of self-registering turnstiles, arranged and operating substantially as and for the purposes set forth. Second, the application to omnibuses, and vehicles of a similar character, of a system of check tickets or counters, substantially as and for the purposes set forth. Third, the improved dust blind and ventilator, constructed and arranged substantially as set forth. Fourth, the application to omnibuses of speaking tubes with branches for intercommunication between passengers, conductor, and driver, substantially as and for the purposes set forth.—Patent completed.

3179 W. PAYNE. *Improvements in clack and bucket door pieces for pumps.* Dated November 11, 1867.

The improvements in clack and bucket door-pieces for pumps herein contained, and consisting substantially in casting on or attaching to each side of the opening of the clack or bucket door-piece, grooves into which the door may slide, giving such a slope or inclination to the inside face of the groove and the outside of the door, which fits against it, as shall have the effect, when the door is let down, of causing it to present against the face of the clack or bucket door-piece, so as to make a tight joint, and the patentee claims the manner of making a more perfect joint in case of need, by using set screws in the manner described, or by inserting in the groove in the inner face of the door, cork, india-rubber, wood, or some more elastic substance than iron, as explained.—Patent completed.

3180 C. B. HODGETTS. *Improvements in tuyeres for blast furnaces.* Dated November 11, 1867.

This invention relates to the construction and arrangement of the parts of tuyeres for blast furnaces, whereby the tuyere is protected against the injurious action of the heat of the furnace, and kept so cool that, in blast furnaces used for the smelting of iron, the melted metal does not attach itself to the tuyere. Tuyeres made according to this invention last longer than ordinary tuyeres. In making a tuyere according to this invention the patentee makes the body of the tuyure in the usual manner, that is, of two hollow cones of different sizes, the smaller one being fixed concentrically within the larger one by annual ends. In the space between the two hollow cones a water pipe is fixed. The said pipe proceeds from the wide to nearly the narrow end of the tuyere. The pipe terminates in a hollow ring surrounding the inner cone. The hollow ring is pierced with a series of holes or jets on the side turned towards the small end of the tuyere. The water with which the hollow conical space is filled is introduced by means of the pipe, and, passing out at the holes or jets in the hollow ring, is delivered directly against the end of the tuyere which is exposed to the greatest heat. The water returns from the narrow end of the tuyere to the wide end, from which it passes away. In order to cause the water on its return passage to play against the outer hollow cone, a collar is made on the inner cone at the back of the hollow ring. The collar directs the water on its return against the outer cone, and keeps it cool.—Patent completed.

3181 S. BUXTON and W. GARDAM. *Improvements in the construction of safety lamps for mines.* Dated November 11, 1867.

The patentees claim, first, a shooting bolt working with a spring, and to withdraw the same they prefer to use a screwed key, screwed either internally or externally, but by preference internally, and by preference with a left-hand thread, and having its fulcrum by means of a shoulder larger than the hole upon the bottom of the oil receiver, and the allowing of the pin's return when the top and bottom parts are put together by the self-action of the spring upon the pin. And, second, the mode of attachment between the top and bottom parts of the lamp by the use of bayonet joints. And, third, the mode of attaching the gauze to the ring, in the manner explained. And, fourth, the use of malleable iron, for the purpose explained.—Patent completed.

3182 G. ELLIS and M. JACOBSON. *A new secret safety desk.* (Partly a communication.) Dated November 11, 1867.

This invention consists in combining with articles of useful and ornamental furniture, a writing desk and cabinet so enclosed as to economize space.—Patent abandoned.

3183 C. E. BROOMAN. *Improvements in apparatus for burning and distilling petroleum and other oils to generate steam, and for other purposes.* (A communication.) Dated November 11, 1867.

This apparatus is constructed with a retort for containing oil, having a steam jacket, or its equivalent, in tubes or chambers, into which steam or its equivalent is thrown for the purpose of heating the oil in the retort. The steam, or its equivalent, rests on the upper or other surface of the oil in the retort, for the purpose of forcing it out through a pipe to a combustion chamber, which pipe is also enclosed in a steam jacket. Atmospheric air is also employed to assist combustion in connection with decomposed steam, both of which are forced in a chamber and distributed in proper proportions with the oil or oil vapour as they all issue from the orifices of the pipes into the combustion chamber. The details of this invention are voluminous.—Patent abandoned.

3184 T. J. LEONARD. *Improved machinery for rolling iron into bars, strips, and sheets.* Dated November 11, 1867.

The object of this invention is to facilitate the rolling of iron by returning the heated metal, after it has passed between the rolls, back to the front of the rolls, so as to repeat the operation with the least possible expenditure of time. By thus quickening the return of the metal to the rolls, the loss of heat is, compared with what takes place with the metal when subjected to the ordinary process of rolling, diminished sufficiently to admit of longer lengths of bars, strips, or sheets being operated upon than heretofore, whereby a great economy will be effected in the process of rolling.—Patent abandoned.

3185 W. R. LAKE. *Improvements in defensive armour for war vessels and forts.* (A communication.) Dated November 11, 1867.

This invention consists in the employment of metal plates made up of alternate layers of iron and steel plates welded together.—Patent completed.

3186 W. R. LAKE. *Improvements in cylinder printing machines, more especially designed for producing coloured patterns upon textile fabrics and paper hangings.* (A communication.) Dated November 11, 1867.

This invention is not described apart from the drawings.—Patent completed.

3187 W. R. LAKE. *Improvements in cartridges for breech-loading firearms.* (A communication.) Dated November 11, 1867.

This invention relates to cartridges provided with an internal cup-shaped anvil, which also serves to strengthen the base portion of the shell. The invention consists, partly, in contracting that portion of the shell in front of the anvil in such manner as to firmly secure the latter, and prevent its displacement by the blow of the hammer or other striker, and to prevent its being dislodged by the action of any gas that may find its way or be generated between the anvil and the base of the shell in firing. The invention further consists in the peculiar construction of the bases of the shell and anvil, and in the means for holding the percussive priming, whereby any liability of accidentally exploding the cartridge, by dropping the same upon a hard surface, is effectually provided against, and whereby the primer is made to serve as a gas check. The gas eliminated by the explosion of the charge, is, by this means, kept from getting between the anvil and the base of the shell, and from driving forward the anvil in the shell, and setting the same tight in the chamber of the barrel.—Patent completed.

3188 W. R. LAKE. *An improved castor for tables, chairs, and other articles of furniture.* (A communication.) Dated November 11, 1867.

This invention consists in the employment in combination with the ordinary parts of such castors of an auxiliary antifriction roller, with a convex periphery, which is supported to turn freely upon a stud or pin attached to the frame of the castor, and arranged to roll upon a concave surface formed upon the foot or leg to which the castor is attached, or upon a circular plate secured upon the same.—Patent abandoned.

3189 W. R. LAKE. *Improvements in breech-loading firearms.* (A communication.) Dated November 11, 1867.

This invention relates more especially to that class of breech-loading firearms wherein the breech is closed by a sliding bolt which is locked and unlocked by turning on its axis, provision being made for inserting the cartridge through an aperture in the barrel or breech receiver when the bolt is drawn back to a suitable position, and the firing of the cartridges being effected by a pin passing through the bolt, and struck by a hammer at the rear of the same. The said invention consists, partly, in the novel construction of the said aperture in the barrel or breech receiver, whereby, while provision is made for easily inserting the cartridges in a proper position relatively to the shell ejector, a firm support is given to the upper part of the breech block or bolt, and its tipping up is prevented. The invention also consists in the novel combination with the block or bolt of a cover for closing the aperture in the barrel or breech receiver when the breech is closed and the bolt locked, which cover is also made to serve as a means for locking the bolt. Also in the peculiar construction of the firing pin and hammer, whereby the possibility of firing the cartridge prematurely or before the recoil bolt is closed and locked, is effectually prevented, while, at the same time, the firing pin is allowed to pass the hammer when drawn back with the bolt in opening the breech. The invention also consists in the construction of the cartridge shell ejector, and in a certain simple provision for cleaning the recoil bolt and breech receiver. The invention cannot be fully described without reference to the drawings.—Patent completed.

3190 W. and W. CAMPION. *Improvements in knitting machinery.* Dated November 11, 1867.

This invention has for its object improvements in knitting machinery, and relates to a novel combination and arrangement whereby ribbed work is produced, and slack courses and welts formed by self-acting machinery. The details of the invention are too voluminous for insertion here.—Patent completed.

3191 F. L. DE GERBETH. *Improvements in treating oils and spirits.* Dated November 11, 1867.

The patentee claims the production of an oil resembling linseed oil, and applicable to printing and varnish making, from a mixture of petroleum or coal iron, or such like hydrocarbon and rosin oil, such oils being treated with oxidizing agents, ozonized air, galvanic electricity, and driers, as described. He also claims the treating petroleum, coal oil, or other similar hydrocarbon oil, with oxidizing agents and galvanic electricity, so as to improve the colour, as described. He also claims the production of a spirit similar to turpentine from a mixture of light petroleum or coil oil, or other similar light hydrocarbon oil or spirit, and light rosin, oil or spirit, such oils or spirits being treated with oxidizing agents, ozonized air, and galvanic electricity, as described. He also claims the apparatus described for the treatment of oils and spirits by means of ozonized air.—Patent completed.

3193 F. and E. L. RANSOME and H. BESSEMER. *Improvements in the manufacture of grindstones and other blocks or forms of artificial stone.* Dated November 11, 1867.

Firstly, the patentees claim, in the manufacture of grindstones and other blocks or moulded pieces of artificial or concrete stone, the moulding or compressing the materials of which such grindstones, blocks, or moulded pieces of artificial stone by means of a vacuum or by pressure, or by both vacuum and pressure combined, substantially in the manner described. Secondly, they claim in moulding articles in artificial or concrete stone, the employment of perforated tubes and hollow or pervious cores for the purpose of facilitating the saturation, washing, or drying of such articles by the employment of exhaust apparatus, or by pressure. Thirdly, they claim moulding artificial or concrete stone on hollow or pervious revolving cores, the requisite pattern or configuration being "struck up" by the employment of suitable scrapers, the material being caused to adhere to and be retained on such revolving core by external atmospheric pressure operating in consequence of the exhausting of such hollow core. Fourthly, they claim rendering waterproof or impervious pipes or other articles moulded in artificial or concrete stone by drawing into the pores thereof, by means of a partial vacuum, in the manner described, fluid asphalte, and bituminous or other matters capable of improving the quality of the stone. Fifthly, they claim making tiles or slabs of artificial or concrete stone having designs or patterns formed of different coloured materials, in the manner described. Sixthly, they claim in the manufacture of grindstones, embedding an iron bush or axis in the material, and also embedding hoops therein, in the manner and for the purposes described. Seventhly, they claim moulding the material known as "Ransome's concrete stone" around the circumference of an iron wheel, having suitable flanges for retaining the same, as described. Eighthly, they claim employing crushed flints in lieu of sand in the manufacture of grindstones of artificial or concrete stone, as described. Lastly, they claim the employment of titaniferous iron, sand alone, or mixed with common silicious sand, in the manufacture of grindstones, as described.—Patent completed.

3194 J. C. BAYLEY and D. CAMPBELL. *Improvements in fire-lighters and fire-revivers.* Dated November 12, 1867.

The composition consists of a mixture of wood, saw-dust, turnings or shavings, tar, and rosin in about the following proportions:—Wood and saw-dust, 28lb.; tar, 18lb.; and rosin, 10lb. The patentees prefer that instead of 28lb. of saw-dust that about one-fourth part of this quantity be wood turnings or shavings.—Patent completed.

3195 H. A. BONNEVILLE. *New and useful improvements in lubricating bores.* (A communication.) Dated November 12, 1867.

This invention consists, first, in so disposing about the shaft, axle, journal, or other bearing, a reservoir or reservoirs for oil or other suitable lubricating medium, and so connecting such reservoir or reservoirs by one or more tubes or other communicating passages extending between it or them, and the bearing of the shaft, axle, or journal, that, by the revolution of the said shaft, axle, or

Digitized by Google

journal, the lubricating medium contained in the reservoir or reservoirs will be drawn or sucked up, as it were, therefrom to the bearing, and, being carried around by the journal, shaft, or axle, is made to lubricate the same. Second, in combination with the above, the invention further consists in providing communication between the bearings of the journal, axle, or shaft, and the oil reservoir or reservoirs for the surplus oil or other lubricating medium to flow back into the same. Third, in so supporting a bearing plate or other surface for the journal, which bearing plate is provided with a communication between it and the oil reservoir or reservoirs, as to have a yielding elastic pressure against the journal. And, fourth, in combination with the same, so constructing such plate upon its outside, and projecting into the reservoir about the communicating tubes, as to form an air chamber or cushion or cushions about the same, and thus, as the journal revolves, drawing the oil up through the communication by its own action, or the action of the air cushion or cushions, or both combined, if any movement occurs to the plate, an additional impetus is given to the oil, and it is made the more perfectly and fully to be diffused or supplied about the journal or axle.—Patent completed.

3196 H. A. BONNEVILLE. *Improvements in machines for pressing or moulding bricks, tiles, or other blocks.* (A communication.) Dated November 12, 1867.

This invention (the details of which we cannot give space to here), will probably be described and illustrated in a future number.—Patent completed.

3197 R. P. FAUCHEUX. *Improvements in tobacco pouches, purses, cigar cases, and bags of various kinds.* Dated November 12, 1867.

The inventor fixes on each side of the opening of such articles, a flat steel or other suitable spring, such springs being connected together at their end in any suitable manner, so that, by pressing upon the ends thereof, the tobacco pouch or other article is opened, and by relieving the springs from pressure, the mouth of such article is closed.—Patent abandoned.

3198 W. H. CRISPIN. *Improvements in the manufacture of artificial fuel.* Dated November 12, 1867.

This invention consists in an improved method of combining coal, coke, charcoal, and other substances adapted for the formation of artificial fuel, when in a state of powder or minute division.—Patent abandoned.

3199 J. T. B. PORTER. *Improvements in rotary spaders or digging machines for tilling land, also applicable to other implements, agricultural or otherwise.* Dated November 12, 1867.

This invention has reference to a previous patent dated March 10, 1865 (No. 671). According to the aforesaid invention a number of spading blades or lines are carried around fixed cams, and forced thereby into the ground as the machine is drawn forward, and the said blades are folded up clear of the ground to allow the machine to be conveniently removed from one field or locality to another. The object of the present improvement is to obviate the necessity of this folding-up of the blades or lines, and the said improvements consist chiefly in the combination with the said machines of a pair of wheels whereon the machine is supported with the blades clear of the ground in travelling from place to place. The said improvements also consist in the devices employed for adjusting the machine into position for either working or travelling.—Patent abandoned.

3200 C. E. BROOMAN. *Improvements in furnaces or heating apparatus.* (A communication.) Dated November 12, 1867.

The object of this invention is the construction of smoke-consuming gasogeneous apparatus which will transform solid combustible matters into combustible gases, and thus satisfy, in an industrial point of view, all that is required of a powerful and smoke-consuming heating apparatus. The essential features which characterize this apparatus or furnace are, first, complete and successive reduction of the fuel in the same apparatus, without interruption of heat, in several communicating fireplaces. Second, ascent and descent of the gases arising from the first combustion or injection of steam or water into the channels which lead these gases from one fireplace to another, or even the draught or suction of a blowing apparatus, as means of increasing their draught, of increasing their pressure, of producing hydrogen by the decomposition of this steam or water, and of facilitating the leading of the gases from one point to another, and of directing them with a certain pressure out of this apparatus. Third, the hermetic and almost continuous mode of charging, owing to the reduced volume of the charge. Fourth, the complete enrichment of the gases developed in all the parts of the apparatus, by causing the gases to return into the apparatus which has generated them in order that they may not issue therefrom until they have been enriched therein through a layer of incandescent fuel. Fifth, the simple and economical mode of heating the new air for burning the combustible gases in a special combustion chamber; and, sixth, a combustion chamber, one of the sides or walls of which is formed with holes by which the burnt gases pass, as through a sieve, in order to enter the apparatus to be heated.—Patent abandoned.

3201 T. EVANS. *Improvements in the manufacture of certain descriptions of buckles.* Dated November 12, 1867.

This invention consists in making double buckles in such manner that both parts of the buckles are movable upon a centre or centres.—Patent abandoned.

3202 M. B. WESTHEAD and R. SMITH. *Improvements in arranging tapes, or other narrow fabrics, in boxes or other receptacles for use.* Dated November 12, 1867.

This invention relates, first, to that system of arranging tapes or other narrow fabrics, for which letters patent were granted to M. B. Westhead, dated November 21, 1863 (No. 2940). According to that invention an elastic medium was used for detaining the coils of fabric and keeping them in form. The patentees now propose to dispense with the elastic medium, and to place the coils or rolls of narrow fabric upon or against each other, with a disc of paper or other thin substance between them. The ends are brought through a slit or slits in the receptacle, and any desired lengths may be drawn off for use without a general disarrangement, for which letters patent were granted to them, dated April 27, 1867 (No. 1242), and consists in placing the narrow fabrics described in a box or other receptacle, in which a slit or slits are formed, and through which the ends of the pieces are drawn, to afford any required lengths for use.—Patent completed.

3203 A. M'KENZIE. *An improved apparatus for opening and closing the heads of landaus, barouches, and other open carriages.* Dated November 12, 1867.

This invention consists of an arrangement of apparatus whereby the heads of carriages may be opened or closed by means of a lever or handle from the driver's seat, the required movement being obtained by revolving "props" in connection with the ordinary outside joints.—Patent abandoned.

3204 L. A. BADIN. *Improvements in bungs for casks, tuns, or other similar vessels for containing liquids.* Dated November 12, 1867.

This invention is not described apart from the drawings. —Patent abandoned.

3205 J. HUMBY. *Improvements in the manufacture of compound metallic plates.* Dated November 12, 1867.

These improvements consist, first, in coating or covering plates of iron with spelter or zinc instead of with tin or other metals, as commonly practised, whereby they are rendered considerably cheaper than tin or terne plates. Second, in coating or covering flat plates or shaped plates of spelter or zinc with copper, whereby they are rendered cheaper than plates of solid copper, or the inventor coats or covers with copper plates of iron coated or covered, with spelter or zinc, as above stated.—Patent abandoned.

3206 J. CARTER and T. CHALMERS. *Improvements in the details and fittings of windows, doors, and other similar contrivances applied to buildings and other structures.* Dated November 12, 1867.

This invention has reference to two former patents, dated respectively June 14, 1876 (No. 1616), and February 16, 1867 (No. 432), and consists in forming the "architraves," "facings," "plates," and other ornamental details, wholly or partly of cast iron, brass, steel, marble, slate, porcelain, glass, encaustic tile or terra-cotta work. The porcelain, glass, or other materials, may be used in different colours, as in encaustic tile work. These can be fixed to the cases by screws very quickly, and, when so fixed, present a more finished external appearance (and at half the cost of masonry) than where cutting or hewing of stone is required. The invention also includes the formation of bases, string courses, corners, and coping of every description of the materials mentioned to be used in combination with stone and brickwork, and will be of great value for covering, protecting, and ornamenting lintels, wood, beams, and other contrivances for the outside of buildings. In brickwork where the walls are 9in. thick, or thereabouts, the wood lintel may be kept all the breadth of the wall, and the outside edge of the same may be protected from the weather by means of an ornamental metal plate and flange.—Patent completed.

3207 J. D. SCALLY. *Improvements in treating casks to render them impervious.* Dated November 12, 1867.

For this purpose the patentee treats the casks with an hydrocarbon, that which he employs being a pure paraffin. The paraffin may be applied to casks in various ways. For example, the cask may first be heated by fire, or by filling it with hot air; some melted paraffin may be then run into it, and the cask rolled about so that the paraffin may be brought into contact with every part of its inner surface. If it be desired to impregnate the pores of the wood still more thoroughly with the paraffin, a pressure of steam or air may be applied to the interior of the cask, so as to force the paraffin into the pores.—Patent completed.

3208 A. F. GAIDAN. *Improvements in compressed or patent fuel.* (Partly a communication.) Dated November 13, 1867.

One part of this invention consists of an improved manufacture of compressed or patent fuel without the admixture of pitch, as at present. For this purpose the patentee mixes together rosin, glue, and salt in a pulverous state, and then mixes this compound with coal dust in the proportions of about from forty to fifty pounds weight of the compound to one ton of coal dust; the latter is at the time warmed sufficiently to render the former adhesive, after which the compound is compressed in the ordinary manner. Another part of the invention has reference to an improved mode of manufacturing patent fuel with pitch. Heretofore, the pitch has first been melted before admixture with the coal dust. Now these improvements consist in pulverizing the pitch, and then mixing it in the pulverous state with the coal dust, the latter being at the time warmed sufficiently to render the pitch adhesive. After incorporation the compound is subjected to the requisite pressure.—Patent completed.

3209 J. W. LOWTHER and T. BENNETT. *Improvements in safety lamps.* Dated November 13, 1867.

This invention consists in improvements in safety lamps for mining and other purposes. The vessel containing the oil is made of any desired shape, but instead of allowing the rods and wire gauze to be attached by screws or catches to the oil vessel, the inventors cause them to be immovably fixed to the said vessel, so that the protecting gauze cannot possibly be removed unless wilfully broken.—Patent abandoned.

3210 F. ANDREW and E. WHITTAKER. *Improvements in printing rollers used for printing colours on hanks of yarns or threads.* Dated November 13, 1867.

This invention relates to those printing machines in which there are two printing rollers having longitudinal ribs of equal or different thicknesses, and consists in so arranging the ribs that two colours can be printed on the hanks instead of one. In these machines all the ribs of the two rollers have hitherto been of equal heights, but, in the patentees' improved rollers, they make them of different heights, and cause the higher ribs of one roller to correspond with the lower ribs of the other roller, so that, by using two colour boxes and two colour rollers, the higher ribs of one roller can print one colour on the hanks, and the higher ribs of the other roller another colour. The invention cannot be fully described without reference to the drawings.—Patent completed.

3211 T. WILSON. *Improvements in the construction of breech-loading firearms, and in the manufacture and construction of cartridges for breech-loading firearms.* Dated November 13, 1867.

The great length of this specification precludes our quoting it here at sufficient length for an intelligible abstract. The invention will probably be described and illustrated in a future number of this journal.—Patent completed.

3212 A. M. CLARK. *Improvements in tubular boilers.* (A communication.) Dated November 13, 1867.

This invention consists in creating a continuous circulation in the tubes, and around the flues, by means of diaphragms or partitions in a much simpler manner than hitherto. This invention is not described apart from the drawings.—Patent completed.

3213 T. TAYLOR. *New or improved implements or apparatus for playing games of skill and chance.* Dated November 13, 1867.

This invention consists in the arrangement of a board or table formed of any suitable material, and with a number of recesses in the central portion thereof, upon which board or table are used pieces of ivory, or other suitable material, formed so as to slide easily along the surface of the said board, to rebound freely from one another, and to fit the recesses. The pieces may be of a circular, diamond, heart, or other suitable shape. The sides of the board are fitted with an elastic cushion, and a semicircular piece, which forms the head of the board, has a similar cushion upon it, and is made so that it can be reversed to enable another person to play from the opposite end of the board. The pieces are struck with a flat circular-headed mace or hammer of ivory or other suitable material, or they may be struck in any other convenient manner.—Patent abandoned.

3214 W. R. LAKE. *Improvements in breech-loading firearms.* (A communication.) Dated November 13, 1867.

This invention relates, first, to the construction of firearms the breech of which is closed by a cylindrical block or bolt which slides and turns in its chamber, and through which extends a pin or rod for exploding the cartridges. The improvements consist, chiefly, in the novel construction of the said block or bolt, in the construction and arrangement of the devices for extracting or removing the shells of the exploded cartridges from the charge chamber, in the peculiar formation of the end of the barrel at the rear of the said chamber, and in the combination with the same of the said bolt and extracting devices. The said improvements, with certain modifications, are applicable to needle guns, and more especially to the so-called "Chassepot" gun. This invention is not fully described apart from the drawings.—Patent completed.

3215 U. PERRENOUD-WURPLEIN. *Improvements in instruments for joining blind cords and other cords.* Dated November 13, 1867.

Here, in order to form a union between the ends of such cords, the patentee employs two coiled springs of wire, into the end of one of which a hook is screwed or fixed, whilst the end of the other receives a corresponding eye in a similar manner. The coiled springs are respectively screwed on to the two ends of the cord to be joined until the ends have entered sufficiently far into the springs to be firmly held. The two ends of the cord thus furnished are then hooked together, and so an endless cord is obtained, which is able to pass very freely over pulleys, such as blind pulleys, and the elasticity of the springs serves to keep the cord tight upon the pulleys, and to compensate for any change in the length of the cord arising from variation in the moisture of the atmosphere.—Patent completed.

3216 R. ADAMS. *Improvements in breech-loading firearms.* Dated November 13, 1867.

This invention is not described apart from the drawings. —Patent completed.

3217 E. MADGE. *Improvements in the mode of, and apparatus for, the reduction of sulphate of iron crystals.* (Partly a communication.) Dated November 13, 1867.

The object here is to effect the reduction of sulphate of iron crystals, commonly called green vitriol, in an economical manner. This product is largely obtained from the spent liquor or pickle used in the manufacture of tinned or terne plates, and it is mainly to the utilization of the product so derived that the invention is directed. The sulphate of iron is first placed on a drying plate, and heat is applied thereto from above, the charge during the process of drying being exposed as much as possible to the action of the air. When the whole, or nearly the whole, of the combined water is evaporated, the product will be a soft porous substance retaining more or less the form of the original crystals. The charge thus prepared is then calcined on a hearth heated from below, but so arranged as to admit the air freely to the charge. The calcination is continued at a sub-red heat until the charge has absorbed a sufficient quantity of oxygen, which will be known by its assuming a light brown-yellow colour, and if not already reduced to powder, it will crush with slight pressure being applied thereto, when it will be in the best possible form for being admitted to distillation. The charge is next placed in retorts, and sulphur fumes are distilled off in the ordinary way. The fumes may be condensed in the usual manner in a leaden chamber, or in simple condensers, as fuming sulphuric acid. The residue is peroxide of iron.—Patent completed.

3218 E. MADGE. *Improved apparatus for feeding metal plates to rolls.* Dated November 13, 1867.

This invention relates to the automatic feeding of plates to rolls. The patentee places the plates which are to be submitted to the rolls in a pile upon a table, which may be conveniently fitted with adjustable side and end pieces for determining the position of the pile thereon, and he brings down upon the pile a sucker or pneumatic holder, which will adhere by slight pressure to a flat surface. This sucker when raised will lift the top plate, and deposit it upon a shute, so situated as to lead the plate to the bite of the rolls. The sucker may consist of an elastic cup fitted in a holder, which may be carried by a transverse frame, or other suitable contrivance, for moving the sucker to and fro between the pile of plates and the shute. The holder he makes hollow to admit air to the cup when the adhesion between the cup and the lifted plate is required to cease, and a valve fitted to the top of the holder will close the air passage. The weight and pressure of the depressed transverse frame will bring the sucker which it carries into close contact with the top plate, and cause its adherence thereto; and the frame with its load will then, by means of suitable gearing, carry the top plate from the pile and bring it over the shute leading to the rolls. At this time air will be admitted to the cup by the raising of the air valve, and the plate will fall upon the shute. This shute is so formed as to reject the feed if by accident two plates are deposited upon it instead of one. A provision of this kind is requisite, as not unfrequently two or more plates will adhere together and be carried up by the sucker and be deposited in the shute.—Patent completed.

3219 A. V. NEWTON. *Improvements in rotary engines applicable as motors, pumps, meters, and for other purposes; also in indicators applicable to such and other engines or meters and other purposes.* (A communication.) Dated November 13, 1867.

The object of the first part of this invention is the con-

Digitized by Google

struction of a rotary engine or device applicable, among other purposes, as a motor, pump, or meter, which, while of a simple character, and free in its movement, is comparatively tight or close against leakage, and readily accommodates itself to inequalities of temperature, as affecting the fit of the revolving slides or pistons, and their attachments with which it is provided, and this part of the invention consists of or includes two cylinders, one within and eccentric to the other, and sliding pistons arranged radially to the inner cylinder, and connected together in a free or loose manner by links to or through the intervention of a loose rivet or pin that forms the centre of motion around which the said pistons with the inner cylinder revolves, by which construction an interior fixed crank pin or eccentric is dispensed with, and the working parts or pistons with their connections are left more free to work close and to accommodate themselves to the various conditions incident to expansion and contraction from changes of temperature. In some cases, however, the said rivet or pin may be stationary and fast to the head of the outer cylinder, with the interior of which it is concentric. The second part of the invention consists in a similar arrangement of cylinders with radially sliding pistons and links connecting them in a free or loose manner with a central rivet or pin, but combines with the same a close chamber arrangement for the sliding pistons within the inner cylinder, and sliding rods connecting the pistons with the links, as aforesaid, for the more effectual prevention of leakage when working the engine with an aeriform fluid. These two divisions of the invention also include or have combined with them revolving heads or end discs to the revolving cylinder with its pistons, the one of which heads may be removable, and the one of which may be left open at its centre, to facilitate adjustment, repair, and oiling of the interior parts. The remaining portion of the invention consists in a novel construction of indicator or registering apparatus applicable to engines or devices contracted as described in the first part of the invention, and which is also applicable to other engines or meters, and for other purposes where quantities or measures of various kinds are required to be recorded, and in which are arranged or combined a series of ratchet wheels disposed one above or in advance of the other, about or around the same axial line, an actuating lever operated at intervals by the engine or meter, and separate or independent pawls to effect the movement of the said wheels, which have pointers connected with them for traverse over a graduated dial plate, and which wheels, or second, and after series of them, are moved for a given distance by a stud or pin attached to the preceding wheel, and operating the ratchet that gives motion to the next wheel in succession, by which combination a compact and simple, yet correct, indicator of measures or quantities is secured.—Patent completed.

3221 R. F. FAIRLIE. *Improvements in the construction of locomotive engines for mountain rail or tramways.* Dated November 14, 1867.

This invention consists in applying to engines for mountain rail or tramways a species of bogie frame, which, together with various other novel arrangements, has the effect of causing the weight of the engine and passengers to assist in enabling the wheels of the engine to bite or take firm hold of the rails.—Patent completed.

3222 J. MORRISON. *Improvements in hem folders and tuckers for sewing machines.* Dated November 14, 1867.

This invention has reference to hem folders of the kind described in the specification of a former patent dated September 30, 1858 (No. 2175). In constructing hem folders according to the present invention, the patentee forms the folder at the end of an arm hinged to a base plate, the arm being capable of being turned on its hinge in a vertical plane for the purpose of introducing the fabric to be hemmed. The base plate is not fixed directly to the sewing machine, but is jointed by a rule joint or other joint to a connecting piece fixed to the sewing machine. By means of the joint the base plate can be turned at pleasure in a horizontal plane out of the way of the needle of the sewing machine. The arm carrying the folder is graduated into inches, and parts of inches, and upon the arm is a spring slide, by regulating the position of which on the arm the width of the hem or of the tuck when the instrument is used as a tucker, as hereinafter explained, may be determined. The slide also serves to fix down the arm carrying the folder, the slide having a finger or projection which engages under the edge of a slot in the base plate parallel to the said arm. When it is wished to raise the arm, the slide is pushed back on the arm till the finger or projection comes opposite to a cross slot, when the arm can be raised, the finger or projection being disengaged from under the edge of the slot. To the end of the arm, and immediately over the folder, a spring plate may be placed, the spring plate having a slot in it through which the needle works. The spring plate serves to guide the edge of the hem, if desirable. When the instrument is used as a tucker, the fabric is passed under the folder and arm carrying it until it comes against the slide, which has been adjusted on the arm to the required width of the tuck.—Patent completed.

3223 P. D. BAVAY. *A method of attenuating the effect of shocks or concussions between engines, carriages, or waggons composing a railway train.* Dated November 14, 1867.

Here a strong iron framework is arranged so as to enclose the locomotive and tender, such framework being supported by guides in which it works freely. It is composed of two rods placed longitudinally, the same being divided at the space between the engine and tender. The ends of the rods are furnished at those parts with buffer heads, and the longitudinal rods are connected at the extremities thereof by two cross pieces, having also buffer heads in the centre. Each carriage of which the train is composed is furnishhd with a strong iron rod, which rod is placed horizontally somewhat above the axles in the axis of the carriage. The rods are provided at both ends with buffer heads, and are supported in guides in which they move freely. The position of the rod of the last carriage is regulated by a screw working in a thread cut in a strong piece of iron firmly fixed to the carriage. All the buffer heads should be so arranged as to touch each other. The apparatus having been thus arranged, and the train started, if the buffer head on the cross piece of the before-mentioned framework which is in front of the engine meets with any resistance which cannot be overcome, the frame will be forced back, as well as all the rods of the carriages, and the last carriage of the train will consequently be the first to stop. The remainder of the train will, by its impetus, continue to pull at the last carriage by means of the draw springs and rods which connect the whole train, and the intermediate carriages, with the tender and locomotive, will be sucessively and not simultaneously stopped, thus preventing the shock which ordinarily occurs when the motion of a train is suddenly arrested. Springs are placed upon the bars which couple the carriages and contribute in a great degree to deaden the shock.—Patent completed.

3224 G. KENT. *Improvements in kneading machines.* (A communication.) Dated November 14, 1867.

The patentee claims constructing kneading apparatus with upright rollers within the kneading vessel, between which rollers the dough is caused to pass, in consequence of the rollers whilst revolving on their own axes being carried round within or performing a circular course in respect to the mixing vessels and its contents. He also claims the arrangement of kneading machines, substantially as described.—Patent completed.

3225 R. HARRISON. *Improvements in cocks or taps.* Dated November 14, 1867.

This invention relates to certain improvements in cocks or taps, suitable either for high pressure water taps or cocks for steam, air, or gases under pressure, the object being to obtain an efficient steam or fluid-tight cock or tap without the use of a stuffing box or packing, as hitherto required for that purpose. The thoroughfare through the cock is closed by means of a valve resting upon a horizontal valve seat, with a packing or facing of leather, in some cases applied either to the face of the valve or to its seat; or the valve may be conical, and fit a conical valve seat, in which case all packing will be dispensed with. This valve is opened and closed by means of a screw spindle, which is either carried by the valve, and works inside a female screw made in a conical cap rotated by the usual "crutch," or by a removable key, if preferred; or the screw spindle may engage with a female screw made in the centre of the valve itself, in which case the crutch for turning the screw spindle is fitted directly thereon, and a conical portion or enlargement is formed on the upper part of the spindle, which is caused to fit accurately into the chamber of the tap or cock, which is also tapered or made conical to correspond to the said enlargement. The accurate fitting together of these two conical surfaces prevents any leakage from the cock, and obviates the necessity for the usual stuffing box or packing. The valve itself is prevented from rotating whilst under the action of the female or male screw, by having a square or other suitably shaped guiding stem formed on its under side, which engages into a corresponding chamber or recess in a hollow cup which closes the lower part of the body of the tap or cock.—Patent completed.

3226 W. H. RICHARDSON. *Certain improvements in the manufacture of iron and steel, and in the means or apparatus for effecting the same.* Dated November 14, 1867.

This invention has reference to three former patents granted to the present patentee, the following being the years and numbers of said patents, which is all that is required for reference thereto:—No. 3189, of the year 1866; No. 1635, of the year 1867; No. 1905, of the year 1867. The patentee claims, first, the employment of hollow tubular tools, either perforated or not, for the purpose of introducing air, steam, or gas into molten metal in puddling furnaces or refineries, whilst the liquid metal is or is not also being stirred about by an ordinary solid rabble, constructed as set forth and shown in the drawings. Second, the employment of a tubular tool or passage for injecting air, steam, or other gas into puddling furnaces or refineries, whilst the metal is also being worked by an ordinary rabble or other solid tool. Third, the arrangement and construction of the hollow revolving tool shown in the drawings.—Patent completed.

3227 J. COMBE. *An improved arrangement of machinery for making cops.* Dated November 14, 1867.

This invention is not described apart from the drawings. —Patent completed.

3228 L. A. WAINMAN. *Improved apparatus for raising water.* Dated November 14, 1867.

The chief objects of this invention are to raise water from mines or wells, or to force water to a great height from a reservoir or water run for driving a water wheel or other purposes. The apparatus can either be worked immersed in the water at the bottom of a mine or well to the depth of the receivers, or out of the water, as may be most convenient. In the latter case the receivers will be fixed as near down to the water as convenient, and the suction pipes carried down into the water. The apparatus is intended to be used with an atmosphere of steam or air admitted to the receivers at any required pressure, which will, of course, entirely depend upon the distance the water has to be forced.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated January 17, 1868.

157 J. Batchelor, contractor, and J. Smith, machinist, Kidderminster, Worcestershire. An improved power loom for weaving Brussels carpets.

Dated January 31, 1868.

339 H. A. Bonneville, Sackville-street, Piccadilly. A new and improved advertising vehicle. (A communication.)

Dated March 24, 1868.

995 E. Gray, Sheffield, steel, saw, file, edge tool, and machine knife manufacturer. An improved mode or method of strengthening or increasing the durability of rails, points, and crossings for railways.

Dated April 1, 1868.

1098 H. H Doty, Bury-street, S.W., Middlesex, and G. Graveley, engineer, Alfred-street, Bow, Middlesex. Improvements in the means or apparatus for producing the more complete combustion of gas, paraffin, and other liquid hydrocarbons.

Dated April 9, 1868.

1192 J. Fitter, Birmingham, gun maker. Improvements in alarums of the kind known as detonating alarums.

Dated April 14, 1868.

1234 B. and A. B. Blackburn, Hans-place, Chelsea, Middlesex. Improvements in rafts or stages to carry passengers, merchandize, articles, and things at sea, and other navigable places, and in the means of propelling the same.

Dated April 17, 1868.

1252 H. G. Fairburn, Goswell-road, E.C., engineer Improvements in portable machinery for turning, screw cutting, boring, and slotting, also for cutting off tubes or solid bars into any required lengths.

1259 W. E. Gedge, Wellington-street, Strand. A novel apparatus for putting boots and shoes on the feet. (A communication.)

1261 J. Erskine, Newton Stewart, Wigtown, Scotland, gun maker. An improvement in the manufacture of breech-loading firearms.

Dated April 20, 1868.

1276 T. A. Warrington, Carlton-road, Kentish Town, St. Pancras. Improvements in candlesticks ann other like articles for holding candles and tapers.

Dated March 21, 1868.

1290 J. Woolfield, St. James-road, Handsworth, Staffordshire. Improvements in the method of, and machinery for, corrugating or fluting sheets of metal.

Dated April 22, 1868.

1312 T. D. Scowen, Allen-road, South Hornsey, Middlesex. A new button hook for boots, shoes, and other articles of clothing.

1319 H. D. Chard, Feniton, Devonshire. Improvements in the construction of buildings.

1322 D. Skeoch, Stewarton, Ayrshire. Improvements in spindles used for spinning or twisting yarn.

Dated April 23, 1868.

1332 J. Armstrong, Masbro' Yorkshire. Improvements in crossings, and in switch apparatus to be used with the permanent way of railways.

1336 J. Rogers, Baxter-road, Islington. Improvements in the preparation and utilization of certain vegetable and bituminous products.

Dated April 24, 1868.

1340 M. Z. D'Aschau, Winsley-street, Oxford-street, analytical chemist. A new vegetable medicinal compound, to be used as a remedy for the cure of scalds, burns, open wounds, swellings, stiff joints, rheumatics, the gout, and other complaints.

1341 I. Baggs, High Holborn. Improvements in the manufacture of white lead, and in the use and application of certain machinery and apparatus for such purposes.

Dated April 27, 1868.

1373 D. Geraci, Florence, Italy. The manufacture of an armour or armour-plating material.

1378 R. Holt, merchant, R. Burlison, mechanic, and H. Sampson, stuff finisher, Bradford, Yorkshire. Improvements in papering and pressing in the finishing of woven fabrics, and in the means or apparatus employed therein.

Dated April 28, 1868.

1387 A. Baal and C. Gann, Jersey. Improvements in reefing fore and aft sails.

Dated April 29, 1868.

1394 S. Robotham, Birmingham, manufacturer. Improvements in bird cages.

1397 W. Wright, Mostyn, Flintshire, copper smelter. Improvements in the manufacture of iron and steel.

1398 A. Geary, Horfield-road, Bristol, ironmonger. A new or improved method of or means for preventing the moustache from dipping into soup when eating it from a spoon.

Dated April 30, 1868.

1409 J. Gough, Kirby-street, Hatton-garden, Holborn-hill, engineer. Improved gearing for actuating the knife in paper-cutting machines.

1411 J. Dendy, and J. B. Beard, Manchester. Improvements in woven fabrics.

1412 J. Betteley, Cavendish House, Bottle, near Liverpool. Improvements in shipbuilding, and in fastenings, bolts, and sheet metal to be used therefor, and for other purposes.

1413 R. Ward, "North of England Advertiser" office, Newcastle-upon-Tyne. Improvements in machinery for spinning or twisting tobacco, and otherwise preparing it for sale.

1415 S. Chatwood, Bolton, Lancashire, safe and lock engineer. Improvements in the construction of safes.

1417 J. W. Goundry, Old Shildon, Durham. Improvements in the means of carrying railway and other tickets, cards, and labels, ready for exhibition or delivery.

1418 B. F. Weatherdon, Law Chambers, Chancery-lane. A new or improved mode of soldering tin boxes, canisters, or cases. (A communication.)

1419 M. A. F. Mennons, Rue de la Chaussee d'Antin, Paris. An improvement in planing, polishing, turning, and other machine tools or apparatus of like description. (A communication.)

1421 T. Beeley, Hyde Junction Iron Works, Chester. Improvements in boilers, and in apparatus for effecting the consumption of smoke in the furnaces of boilers.

Dated May 1, 1868.

1423 J. Lillie, Manchester, engineer. Improvements in apparatus for regulating, measuring, and registering the flow of liquids.

1424 C. D. Abel, Southampton-buildings, Chancery-lane. The production of a new or improved colouring matter from aniline. (A communication.)

1425 E. Leheup, Octagon-place, Upper Summerford-street, Bethnal Green. Improvements in the manufacture of wooden boxes.

1427 A. B. Childs, Mark-lane, City, engineer. An improved apparatus or machine for separating mixed, powdered, or other substances.

1428 J. Warne, Blackfriars-road, Surrey, beer engine manufacturer. A new or improved union junction or fastening for pipes and tubes.

1429 W. E. Everitt, Birmingham, tube manufacturer. Improvements in the manufacture of copper, brass, and metal tubes.

1431 J. H. Johnson, Lincoln's Inn-fields. Improvements in machinery or apparatus for burling and shearing textile fabrics. (A communication.)

Dated May 2, 1868.

1432 J. Heaton, Langley Mill, Derbyshire. Improvements in reverberatory and other furnaces.

1433 F. Barnett, Rue de Rivoli, Paris, merchant. An improved unspillable pail or vase.

1436 T. Hawkes, F. W. and G. Spencer, agricultural engineers, and J. Stenner, foreman, Tiverton, Devonshire. An improved seed and manure drill, parts of which invention are also applicable to other similar agricultural implements.

1437 E. G. Camp, College Green, Bristol, toy vendor. Improvements in mallets used in playing the game of croquet and in similar games.

1438 L. Binns, Brighouse, Yorkshire, worsted manufacturer. Improvements in looms for weaving.

1439 H. Y. D. Scott, Ealing, Middlesex, Lieut.-Colonel in the Royal Engineers. Improvements in kilns for burning lime and cement.

1441 A. Smith, Stratford, Essex. Improvements in apparatus to be used in connection with furnaces for burning creosote and other combustible liquids.

1441 J. E. Boyce, manufacturer, and R. Harrington, warehouseman, Birmingham. Improvements in umbrellas and parasols.

1443 J. H. Johnson, Lincoln's Inn-fields. Improvements in apparatus for exhibiting minute photographic pictures, and in pictures or slides to be used therewith. (A communication.)

1445 J. L. Budden, Fenchurch-street, City. Improvements in machinery or apparatus for drying wool or for discharging moisture from fibrous, granular, or other materials. (A communication.)

1447 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in dynamometers. (A communication.)

Dated May 4, 1868.

1448 H. Glover, New Church-street, Bermondsey, Surrey, engineer. Improvements in means for retaining corks or other stoppers in bottles.

1449 W. E. Gedge, Wellington-street, Strand. An improved process of applying a coating of silver upon any animal, vegetable, or mineral substance. (A communication.)

1450 A. Vickers, Inverness-terrace, Bayswater. An improved mode of locking the nuts of screw bolts. (A communication.)

1451 I. Mather, Anvers, Belgium, merchant. Improved apparatus for warehousing petroleum, mineral or essential oils, and other liquids.

1452 C. P. Aston, Chelsea, Middlesex. Improvements in chimney tops or pots.

1453 J. Wertheim and L. Hirschhorn, carrying on business as M. Goldschmidt and Son, Hatton-garden, Holborn-hill. Improvements in lockets. (A communication.)

1454 T. and G. A. Pemberton, Birmingham, brass founders. Improvements in alarm bells, call bells, and other bells.

1455 E. and G. H. Morgan, Edgware-road, Middlesex. Improvements in carriages.

1456 W. Marshall, Old Basford, Nottingham, clipper of lace. Improvements in machinery or apparatus employed in the clipping of lace and other fabrics.

Dated May 5, 1868.

1459 D. P. Wright, Birmingham, lamp manufacturer. Improvements in the manufacture of certain descriptions of taps.

1460 W. Taylor, Woodstock-road, Poplar, Middlesex. Improvements in the construction of iron and steel ships, and other floating bodies, and in the mode of attaching or connecting and fixing wood planks to the sides and bottoms thereof, to receive the metal sheathing and other external and also internal fittings of iron and steel ships, and other floating bodies.

1461 W. Sketchley, Weymouth, Dorsetshire, machinist. Improvements in machinery for wood cutting, joinery, and mortising.

1462 C. W. Siemens, Great George-street, Westminster. Improvements in the manufacture of cast steel, and in working furnaces in connection therewith.

1463 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in axle-boxes for the rolling stock of railways. (A communication.)

1464 F. W. Gerhard, Wolverhampton, chemist. Improvements in motive power engines actuated by steam or other vapour.

1465 J. Dawber, Over Darwen, Lancashire, engineer. Certain improvements in steam engines.

1466 J. Clough, Grove Mill, Keighley, Yorkshire. Improvements in screw gill boxes for preparing wool and other fibrous substances.

1467 J. Hickmott, Clapham, Surrey, engineer. Improvements in preserving metallic articles from oxidation and decay.

1468 J. Court, Sheerness, Kent. Improvements in traps or apparatus for receiving sewage matters, and separating the solid from the liquid portion thereof.

1469 G. Kent, High Holborn. Improvements in ice preservers, refrigerators, and ice safes.

1471 W. Beale, Taunton, Somersetshire, builder. Improvements in step and other ladders.

1472 W. Walker and H. F. Smith, Hull, seed crushers. Improvements in apparatus employed for expressing oils from seeds or other substances.

1473 F. J. King, Leadenhall-street, City, manufacturer. Improvements in the mode of preparing potatoes for preservation.

1474 J. Lamb, machinist, and S. Tovey, auctioneer, Kidderminster, Worcestershire. Improvements in bobbin frames for carpet looms.

1475 W. E. Newton, Chancery-lane. Improvements in machinery for forming pickaxes and other tools. (A communication.)

1476 J. Wilkinson, jun., St. Helen's Mills, Hunslet, Leeds. Improved machinery for printing carpets.

Dated May 6, 1868.

1477 A. Scott, Blomfield-crescent, Paddington. Improvements in the present method or means of attaching clothes to the person.

1479 R. Lublinski, City-road, Middlesex, stick manufacturer. Improvements in fasteners for the tips of umbrellas and parasols.

1480 T. Warren, Glasgow, glass manufacturer. Improvements in glass and other furnaces.

1482 C. J. Chubb, Canterbury House, West End, Hampstead. An improved mode of getting coal, slate, or other minerals, and an improved apparatus for effecting the purpose, which apparatus is also applicable to other uses.

1483 J. and J. B. Palmer, Palace Works, Old Ford-road, Bow. Improvements in the manufacture of friction matches and fuzees. (A communication.)

1484 H. J. Davies, Dalton in Furness, Lancashire. Improvements in compositions for cleaning gold, silver, and plated goods.

1486 S. Drummond, Ardwick, Manchester, salesman, J. Clare, Greenfield, Saddleworth, Yorkshire, manufacturer, and R. Hughes, Didsbury, Lancashire, salesman. Improvements applicable to the prevention of fraud in the collection of fares in omnibuses and other carriages, and in apparatus connected therewith.

1488 W. E. Newton, Chancery-lane. Improvements in combs. (A communication.)

1489 M. Henry, Fleet-street, City. Improvements in the manufacture of steel and iron and other metals, and in furnaces employed in the said manufacture. (A communication.)

1490 S. Holt, colliery agent, and J. Kearsley, carriage builder, Manchester. Improvements in means or arrangements for making observations on railways for the purpose of preventing accidents, and in signalling or communicating between one part of a railway train and another.

1491 J. G. Walker, Bonnington, Mid Lothian, and C. Stein, Leith, Mid Lothian. Improvements in separating tares and other impurities from grain and other seeds, and in the apparatus or means connected therewith. (A communication.)

1492 J. G. Walker, Bonnington Steam Mills, Bonnington, Mid Lothian. Improvements in dressing millstones, and in the machinery or apparatus employed therefor.

1493 W. Harvie, Glasgow. Improvements in the construction of lamps and lanterns, and in lenses employed therewith.

1494 J. H. Johnson, Lincoln's Inn-fields. Improved means for increasing the draught in steam boiler and other furnaces or fireplaces. (A communication.)

Dated May 7, 1868.

1495 M. A. Muir and J. M'Ilwham, Glasgow, machinists. Improvements in power looms.

1496 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in spring mattresses and seats. (A communication.)

1498 R. A. Green, Strand. Improvements in bearings, shafts or pivots, applicable to machinery, apparatus, instruments, and other useful purposes.

1499 A. C. Henderson, Charing-cross. Improvements in the manufacture of plates for hellographic engraving. (A communication.)

1500 A. C. Henderson, Charing-cross. An improved mode of renovating files by an electro-chemical process. (A communication.)

1502 R. Harlow, Heaton-Norris, Lancashire, brass founder. Improvements in apparatus for supplying water to, and withdrawing water from, baths, wash-basins, and other receptacles.

1504 J. H. Johnson, Lincoln's Inn-fields. Improvements in sewing machines. (A communication.)

1506 W. E. Gedge, Wellington-street, Strand. An improvement in throstle frames for spinning flax, tow, hemp, jute, silk, wool, or cotton. (A communication.)

1508 J. Bruce, engineer, and R. Evans, miller, Birmingham. Improvements in bolters used for dressing flour, and for other like purposes.

Dated May 8, 1868.

1512 W. Husband, Hayle, Cornwall, and F. B. Doering, Victoria-street, Westminster, civil engineers. An improved mode of, and apparatus for, securing or holding the stands or frames of rock-boring or excavating machines, part of which apparatus is applicable to connecting such machines with their stands or frames.

1514 A. James, Redditch, Worcestershire, needle manufacturer. Improvements in machinery for polishing needles.

1516 J. A. Jones, Middlesborough, Yorkshire, engineer. Improvements in the manufacture of iron and steel.

Dated May 9, 1868.

1518 J. C. Bowler, Bowden, Cheshire. Certain improvements in castors or similar rolling supports for furniture.

1520 W. E. Everitt, Birmingham, tube manufacturer. Improvements in casting copper tubes and cylinders.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated May 13, 1868.

1559 J. W. Chamberlain, Massachusetts, U.S. An improvement in steam engines. (A communication.)

Dated May 16, 1868.

1619 M. A. Hamilton, Southampton-buildings, Chancery-lane. An improved churn.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," May 26, 1868.

3723 J. G. Crompton. Apparatus for the manufacture of felt hats.

114 T. S. Ellin. Self-securing skate. (A communication.)

127 A. B. Boyer. Construction of aerial cradles.

130 L. M. Becker. Laying and supporting the wires used for electric telegraph.

131 G. Nimmo. Composition for furnace linings.

135 W. Ayliffe. Boats, and in the means of steering the same.

148 J. Wood. Windows.

152 T. Nash. Stoves.

155 F. Postill. Kilns for burning bricks.

157 J. Batchelor and J. Smith. Power loom for weaving Brussels carpets.

159 J. Moorhouse. Machinery known as cone drawing employed in preparing wool.

162 J. Hosking. The cutting heads of instruments used in drilling rock.

164 H. Aitken. Treating iron ores.

167 D. A. Fyfe. Manufacturing paper pulp from wood.

172 J. Millward. Apparatus for propelling ships. (A communication.)

176 E. Dorsett. Utilization of coal tar.

185 W. E. Newton. Kilns for baking porcelain. (A communication.)

191 J. Davies. Machinery for shaping malleable materials.

192 T. G. F. Dolby. Feeding bottles.

194 M. Robinson. Manufacture of expanding and contracting combs or reeds.

199 A. M. Clark. Steam boilers. (A communication.)

201 J. Parsons. Double-barrel breech-loading firearms.

214 J. H. Johnson. Apparatus for indicating the relative positions and movements of certain of the heavenly bodies. (A communication.)

216 W. Davis. The method of fastening bags made of paper for the conveyance by post of samples of grain.

220 A. B. Brown. Actuating the valves of engines worked by steam.

222 J. Dixon. Construction of floating saloon baths.

226 W. Thompson and T. Stather. Mills for grinding.

229 E. Tomlinson. Apparatus for ornamenting and manufacturing articles from wood.

231 T. Goune. Canteen.

232 C. S. Barker. Construction of organs.

244 H. J. Dickinson. Tables for playing billiards.

250 G. Severn. Valvular apparatus for giving vent to casks.

252 J. and D. Storer. Vessels for holding liquids.

268 E. J. W. Parnacott. Manufacture of elastic rollers.

270 A. M'Dougall. Apparatus for burning sulphur ores.

279 W. E. Rendle. Structures for protecting fruit trees from frost.

303 W. H. Richardson and W. Beardmore. Process to be used in the manufacture of iron and steel.

315 S. M. Martin and S. A. Varley. Electrical train intercommunication.

336 J. Walker and J. Hudson. Machinery for turning wood.

347 A. M. Clark. Steam engines. (A communication.)

364 J. H. Johnson. Treatment of bones. (A communication.)

371 J. H. Johnson. Treatment of compressed wood. (A communication.)

384 J. Webster. Means of preventing incrustation in steam boilers.

485 R. George. Gas stoves.

538 A. M. Keighley. Apparatus for signalling from one part of a railway train to another.

587 W. Wilson. Apparatus for lubricating the sliding valves of steam engines. (A communication.)

595 J. J. Aston. Propellers applicable for the propulsion of ships.

627 J. C. Davies and E. Zahn. Muffs.

965 H. Bessemer. Manufacture of refined iron.

967 H. Bessemer. Manufacture of malleable iron and steel.

1095 H. Bessemer. Manufacture of malleable iron and steel, and in the melting of metals.

1366 A. Parkes. Manufacture of varnishes.

1403 H. Deacon. Manufacture of chlorine.

1462 C. W. Siemens. Manufacture of cast steel.

1465 J. Dawber. Steam engines.

1475 W. E. Newton. Machinery for forming pickaxes. (A communication.)

1559 J. W. Chamberlain. Steam engines. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 22, 1868.

3325	M. A. Hamilton	3521	G. H. Nick
3326	T. Barton	3689	W. E. Newton

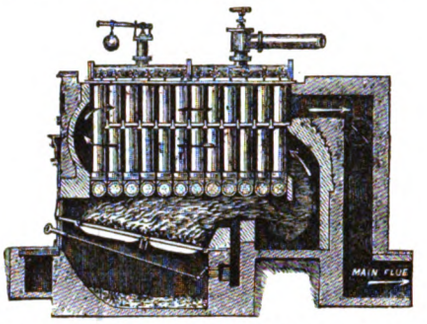
HOWARD'S SAFETY BOILER.

AND SUPERHEATER.



IS NOW AT WORK IN LONDON AND VARIOUS PARTS OF ENGLAND.

ADVANTAGES:—

Perfect Safety from Explosion.
Economy of Fuel and Consumption of Smoke.
No Seams or Rivets.
Saving of Cost and Time in Repairs.
Portability.

Can be fixed in places Inaccessible to Cornish Boilers.
High Pressure and Dry Steam with Perfect Safety.
No Leaky Joints.
Perfect Circulation, consequently little or no Incrustation.

COST.

When all the above considerations are weighed, J. and F. HOWARD'S Boilers will be found the Cheapest and Best ever produced.

Boilers which have been in use many months are now perfectly clean.
They can be seen at work, and tubes taken from them for examination, on application to

J. & F. HOWARD,

BRITANNIA IRON WORKS, BEDFORD.

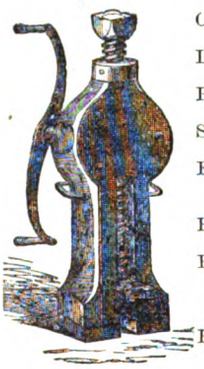
PATENTEES AND MANUFACTURERS OF AGRICULTURAL MACHINERY, INCLUDING
STEAM CULTIVATORS, STEAM PLOUGHS, CHAMPION PLOUGHS, HARROWS, HORSE RAKES, HAYMAKERS
MOWING AND REAPING MACHINES.

THE FIRST GOLD MEDAL AS WELL AS A GRAND PRIZE AT PARIS, 1867.

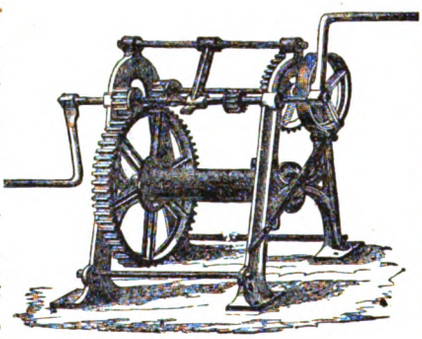
LONDON OFFICE:—4, CHEAPSIDE, THREE DOORS FROM SAINT PAUL'S,
Where Boiler Tubes, Models, and Drawings can be seen. B 19

THOMAS WORSDELL,

MANUFACTURER OF



Cranes, Crabs, Pile Drivers, Steam or Hand.
Overhead Traversers, Chains, Blocks, &c.
Lifting Jacks, Traversing, Windlass, &c., Hydraulic, and others.
Pulley Blocks and Patent Differential ditto.
Screwing Tackle for Engineers, Gas, &c.
Engineers' Tools, Ratchet Drills, Bear Punches, Smiths' Forges, Anvils, Vices, &c.
Hydraulic Machines to Test Girders, Bars, Hoops, and Wire.
Platelayers' Tools, Rail Presses, Jim Crows, Hammers, Levers, Picks, Drilling and Punching Machines, &c.
Railway Screw Couplings, Wire Strainers, Screw Bolts, Washers, Rivets, Chains, &c.



N.B—PRICES CONSIDERABLY REDUCED.

BERKELEY STREET, BIRMINGHAM. A 53

WOOD BROTHERS'

PATENT OBLIQUE TRANSVERSE TUBES

For the Flues of Cornish Steam Boilers.

THESE Tubes are exceedingly simple in construction and application, and very durable. They give a greater amount of heating surface than any other transverse tube that can be put in a flue of the same piameter, consequently will generate more steam with greater economy of fuel, and they can be repaired or replaced much more readily than any others.

As these Tubes are put in obliquely, and at a proper inclination, having the flanches at both ends inside the flue, they may be put in or taken out of their places through the flue without passing inside the boiler at all, thus giving the opportunity of applying them to boilers already in use without disturbing them or taking out the flues, whatever be the relative dimensions of the shell and flue.

FOR PRICES, AND A LITHOGRAPH OF THE BOILERS, APPLY TO

WOOD BROTHERS, DON BOILER WORKS, SHEFFIELD

B 1

THE BEST REMEDY FOR INDIGESTION.

NORTON'S CAMOMILE PILLS are confidently recommended as a simple but certain remedy for Indigestion. They act as a powerful tonic and gentle aperient, are mild in their operation; safe under any circumstances; and thousands of persons can now bear testimony to the benefits to be derived from their use.

Sold in bottles at 1s. 1½d., 2s. 9d., and 11s. each, in every town in the Kingdom.

CAUTION!—Be sure to ask for "NORTON'S PILLS," and do not bepersuaded to purchase the various imitations. A 54

WM. WARNE and Co., Sole Manufacturers of the PATENT VOLUTE HOSE; Consolidated Emery Wheels, Improved Junction Rubber for Valves, Pump Buckets, Steam Packing, Hydraulic Rams, Gas Works, &c. Ferruginous Cement Packing, India-rubber Mats for doorways, baths, &c.; the Sultan's Bath Brush and Hand Emollient; the Prince of Wales's Self-closing Pinches; the Junction Rubber Soles for boots and shoes, &c., and the Mineralized (Red) India-rubber for Valves, &c. Manufacturers also of all descriptions of Vulcanized India-rubber Sheet, Valves, Washers, &c.; Hose Pipes, Tubing, &c.; Waterproof and Air-proof Goods, &c.

WM. WARNE & Co., 9, Gresham-street West, E.C., and Tottenham, N. A 33

COCKER BROTHERS
(Successors to Samuel Cocker and Son),
SHEFFIELD.
ESTABLISHED 1752,
MANUFACTURERS OF STEEL FILES AND WIRE; Also of "COCKER'S" PATENT STEEL ROPE WIRE
In long lengths, from 10lb. to 40lb. pieces, without welding, and capable of bearing as high a breaking strain as any in the market. Each piece warranted to twist round its own diameter.

Three First-Class PRIZE MEDALS were awarded to SAMUEL COCKER and SON, Sheffield, at the Great Exhibition of Industry, London, 1851,

First-class PRIZE MEDAL was awarded to COCKER BROTHERS at the Universal Exhibition of Industry, Paris, 1855, and MEDAL of HONOUR awarded to COCKER BROTHERS, by the Society of Arts and Industry, London, 1856. A 26

MOULTON'S PATENT EMBEDDED STEEL AND INDIA-RUBBER SPRINGS for Railway Carriages, Locomotive Engines, Buffers, &c., possess greatly-increased power, as compared with the ordinary India-rubber Springs; are more uniform in their action, counteract the compressibility of India-rubber alone, and are not liable to break from sudden concussion, or the inequalities of the permanent way.

Prices and further particulars may be had on application to the Patentees, S. MOULTON & CO., Manufacturers of India-rubber Springs, Steam Packing, Washers, Hose, Tubing, Machine Belting, Garments, Blankets, Sheeting, Elastic Hot Water Beds, Cushions, &c., &c.
Kingston India-rubber Mills, Bradford, Wilts. A 34

WROUGHT IRON TANKS, CISTERNS
GIRDERS, FUNNELS, &c., Plain or Galvanized.

Cattle Troughs, Iron Cart Bodies, &c.
GALVANIZED OR LEAD SERVICE PIPE, BRASS BALL VALVES, ETC.
Merchants and Shippers Supplied.

HENRY WATSON & Co.,
60, VAUXHALL STREET, LAMBETH, LONDON. A 29

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, JUNE 5, 1868.

THE CUBA AND FLORIDA CABLE

IN our remarks of last week we referred with gratification to the activity now going on in submarine telegraphy. We alluded to the various submarine cables in course of construction, and those about to be commenced. We propose, as each one is completed, to give full details of its construction and manufacture, so that our readers, and especially those interested in telegraphy, may be *au fait* as to the recent improvements that will, as a matter of course, be constantly brought forward. We commence by first giving—carrying out our promise of last week—a description of the Cuba cable, to which we have made allusion on more than one occasion. The passage across the Gulf Stream from Key West to Florida is one of great danger to a submarine cable. On the American side it must necessarily pass through a great number of coral reefs; it then crosses the main portion of the Gulf Stream in deep water, and is landed on the Havana side on a precipitous rocky coast, for the water deepens almost immediately into about 1,000 fathoms. Being, we believe, somewhat afraid of the cable laid last year not lasting (from the causes mentioned) a great length of time, the International Ocean Company decided upon laying a new cable across between the same points. The fact of their being able to raise the money for another cable is great evidence in favour of the large commercial business that must be transacted between Cuba and the United States, and in view of the probable extensions to Panama and to Jamaica, we doubt not that plenty of business will be found to accommodate both wires.

General Smith, the President of the American Company, came over some short time back to arrange for the manufacture of the cable. Terms were arranged, and the India-Rubber, Gutta-Percha, and Telegraph Works Company were entrusted with the manufacture of this cable at their works at Silvertown, as they had been with that of the previous cable. They were bound to have it made and shipped on board the "Narva" within a certain time. This part of the contract has been speedily fulfilled, and the "Narva" is now away with the cable on board bound for Key West.

The cable is of a somewhat similar character to that submerged last year, differing principally in the fact that it is protected externally with Clark's bituminous compound. In length it is 105 miles, and is divided into three sizes—main deep-sea cable, intermediate, and heavy shore end, of the lengths of 91, 7½, and 6½ miles respectively. The major portion of the intermediate and heavy shore ends will be submerged in comparatively shallow water amongst the coral reefs off Key West; the shore at Havana shelving so abruptly necessitates only a very short amount of shore end. The conductor of seven copper wires, weighing 107lb. per nautical mile, was stranded and coated with the dielectric at the Silvertown Works, and consisted of three coats of gutta-percha, laid on with alternate coatings of a compound of tar and percha, the first coating of compound being placed next the stranded conductor. The weight of gutta-percha was 166lb., making the combined weight of conductor and insulator equal to 273lb. per nautical mile. The conductor thus insulated was carefully tested, after being kept for twenty-four hours in water at a temperature of 75deg. Fah. It was then served with two servings of tanned jute, and coiled in tanks ready to be protected with its external sheathing.

The core for each sort of cable remained the same, the difference being only in the size of the wires used for the outer sheathing; this for the main deep sea cable consisted of 12 B.B. galvanized iron wires of No. 9 gauge, further protected by two servings of tarred jute, each coated with a good coating of Clark's bituminous asphalte compound. The intermediate cable was sheathed with 12 B.B. galvanized iron wires of No. 5 gauge, protected with two servings of jute and compound similar to the main cable. The heavy shore end consisted of intermediate cable, further protected by an extra sheathing of 14 B.B. galvanized wire No. 1 gauge, and covered with jute and compound. This made a most substantial cable, and one that will evidently prove a hard job for the coral reefs. The weights of the various sizes were respectively three, ten, and twenty tons per nautical mile. The cables as manufactured are as fine specimens of submarine cables as we have ever seen, and the insulator and conductor are the best of a similar kind that have as yet been sent away from any factory. Too much credit cannot be given to the Silvertown Company for the attention they have given to gutta-percha as an insulator, and to the high state of perfection to which they have brought it. Although the quality of the gum is only slightly better than that from which the Cuba cable of last year was manufactured, yet the manufacture of the article has so much improved that the present core tests, being reduced to a temperature of 75deg. Fah., above 87 per cent. better than that of last year. Several gentlemen, well known for their experience in testing submarine cables, have experimented and reported most favourably upon it; and by the permission of Mr. Matthew Gray, the managing director of the company, we are enabled to give for the information of our readers a *resumé* of the final tests taken by their electrician, Mr. Hawkins, which we ourselves have had an opportunity of verifying. This information we tabulate, and for the sake of comparison give similar details of last year's cable :—

	1868.	1867.
Conductor, weight per knot	107	107
Insulator, weight per knot	166	166
Conductor, resistance per knot at 75 Fah.	11·8 Ohms.	12·38 Ohms
Conductor, specific conductivity, pure copper, 100	94·4	90·01
Dielectric, resistance per knot at 75 Fah.*	871 Megohms.	464 Megohms.
Dielectric, electrostatic capacity per knot	0·3663	0·3507 Farads†

The contract specified the conductivity of the conductor to be 85 per cent. of pure copper, and the resistance of the dielectric at 75deg. Fah. to be not less than 250 Megohms. A reference to the table will show the superior quality of the materials supplied.

We must not omit to mention that the wire was supplied by Messrs. Johnsons, of Manchester, and the larger size is something really very fine. It is of rolled iron, and is produced in longer lengths than wire usually is. The lengths average about 140lb. each, without weld. The advantage of using such long unbroken lengths is very great, as it dispenses with a great number of welds. The only ones that are now necessary are those made at the closing machine, which, from the amount of attention they receive, have always been superior to any others.

The engineering supervision of the works was placed under Sir Charles Bright, who was also engaged by the company to submerge the cable. For this purpose the "Narva," Captain Nisbet, was again chartered. She was last year fitted up for the Silvertown Company, expressly for the work, with iron water-tight tanks, and a most complete set of machinery, by Mr. F. C. Webb, C.E., from his own designs, many of which were quite novel. All these have again come into use, as the Silvertown Company agreed to fit the ship up in a manner similar to last year's expedition, and our readers can imagine that a large amount of labour and expense has been saved by their being able to use a complete set of apparatus that had only to be put in the places which were formerly occupied by them. The "Narva" is now on her way to Key West; she leaves a month earlier than the expedition of last year, and as she has much less work to perform, we trust that she may be able to accomplish all before the dreaded "vomito" makes its appearance. After the experience of last year, we cannot help again expressing our surprise that the work should be undertaken at such a season, but now that they have done so, we cannot but, in the interests of submarine telegraphy and commercial enterprise, wish them every success.

* For comparison with other cables, see Latimer Clark's table published in our number of April 24 last.

† The Farad. is the standard unit of capacity appointed by the British Association.

IMPERIAL ESTABLISHMENTS ON THE LOIRE.—No. I.

TO the discovery of the wonderful powers of steam, and the universality of its application, may be fairly attributed the condition of decay and disuse into which water power has fallen, not only in our own country, but in others where the new motor has been introduced. Had it not been for the birth of that invincible force, the enormous amount of water power existing even in the comparatively insignificant streams of the United Kingdom, would have been utilized to a maximum, instead of being permitted to remain, at the best, useless and idle, and, at the worst, a scourge and a terror to those dwelling within reach of its influence. Were our rivers more under command, their channels less winding, their beds less obstructed, their depth more constant, and their flow more uniform, the plea so often put forward by the manufacturer and the mill-owner, that he cannot obtain a constant supply of water, and must, therefore, have recourse to the agency of steam, would not be so forcible or so incontrovertible as it unfortunately is. One might imagine that although rivers are but little used as a source of power, yet means would have been taken to restrain them within their channels, and so avert the consequences which inevitably attend their annual inundations. But it is not the case. Neither in England or in France have the great rivers been placed under any restraint, except in a few isolated instances, and then only for a distance so short that it merely suffices to render the stream more impetuous after escaping from its temporary fetters. Of the continental rivers, the Loire is one of the most important, not only in actual size, but also for the extent of its course. Rising within a few miles of the source of the Rhone, it traverses France from east to west, and, together with its tributaries, which are numerous and considerable, it irrigates an extent of country forming nearly half the empire. If the works and operations commenced by the Valois had been continued by their successors, this enormous area of land would have been irrigated in the true and beneficial sense of the term, instead of being visited, upon the average, every ten years with inundations that spread far and wide ruin, terror, and desolation.

Among the numerous establishments situated upon the Loire, that upon the Isle of Indret has the merit of antiquity, and enjoys the favour of governmental patronage. This little island was selected about the year 650, as a suitable spot for a colony of ecclesiastics,

Digitized by Google

who, from the number of caves in it, bestowed upon it the name of Antrum. In the process of time, when the Latin tongue fell into disuse, and other than monks and nuns resorted to the locality, the original name was altered to Aindre or Aindrette, and ultimately to Indret, which is its present denomination. It was not until the year 1650 that Indret became the property of the Crown, and was used as a dockyard for the construction of the ships of that period. In 1777, a cannon foundry was established there by order of Louis XVI.; the celebrated English engineer, Wilkinson, was appointed manager, and the works were carried on with an energy and activity that always characterized the industrial projects of that monarch. After the departure of Wilkinson, which took place some five years subsequently, the premises became the property of a company, and during their occupation a large fire pump was manufactured, one of the first steam machines constructed in France, and contemporary with that put up at Creusot. Unfortunately, not only this curious relic of early machinery, but all its numerous adjuncts and accessories, have been either purposely destroyed or suffered to decay, when their services were superseded by those of more modern agents. At the beginning of the present century, Indret passed into the hands of the French naval authorities, and, in 1827, the Minister of the Navy determined upon employing the foundry and other workshops upon a much larger scale than had been hitherto attempted. The situation of Indret upon a navigable river offered at that time, when railways had not been created, facilities not possessed by other localities farther inland. From this time the resources of the imperial establishment began to receive a considerable development, and the result of its capabilities was demonstrated at the recent "Exposition" by the display of a motive agent equal to 4,000-horse power, constructed with a skill and workmanship that may challenge those of any specimen of machinery. Among the machines upon the premises are a Whitworth planing machine of 1841, which is still at work, although the principle has been nearly superseded by more modern examples of the same implement. There are numerous others bearing the names of Fox, Sharpe, Roberts, Harvey, Mazeline, Elvell, and Ducommun, thereby indicating the various alterations that have been introduced from time to time by mechanical genius. If the older examples of machinery be contrasted with those of a modern date, it will be found that the complicated has been invariably succeeded by the simple, and that the aim of the designer is no longer to introduce fanciful and conceited novelties of construction, but to effect the maximum production of work with the minimum expenditure of labour.

Formerly it was a labour to even file iron: now it is planed like wood, melted like wax, and cut and pierced like a piece of cardboard. At Indret there are machines powerful enough to plane off a strip of wrought iron more than 1½in. in thickness and 40ft. in length, the cutter being carried backwards and forwards by a slide weighing nearly fifteen tons. The majority of the work is effected by portable engines of fifteen horse-power, and placed in pairs close together, so as to relieve one another, and thus prevent any interruption in the operations in progress. A machine, or, rather, an apparatus, invented by M. Joessel, for testing castings by the determination of their powers of resistance to rupture, and also ascertaining their elasticity, is in constant use upon the premises. It consists of a steelyard which registers the loads and the deflections at any particular moment of the testing, by means of the movable drum attached to an indicator of M. Garnier. All the bars to be tested are reduced to the standard dimensions of 2in. square, and the registering portion of the apparatus is composed of a lever movable upon a centre, and carrying a weight at one of its extremities. Between the weight and the fulcrum a knife is fixed, the point of which transmits to the bar the pressure of the weight. Two other knives are placed under the bar, and it is at the middle of the distance that separates them that the point of the upper knife acts. This knife and the weight can be shifted by means of a screw to any position upon the lever. In proportion as the weight is moved towards the extremity of the beam, so the pressure increases, and its amount is recorded by a pointer upon a scale. A lever, terminated by a needle movable about a dial, registers the deflections multiplied ten times. Reliance must not be placed solely upon the indications of this apparatus in judging of the strength of castings. Due regard must be had to the method of casting employed, especially to the temperature of the metal and that of the mould, and precautions must be taken that the iron is of good quality, and that the specimens selected are fair representatives of the usual productions of the foundry. Nothing is more common in all testing operations than to select specimens which are superior in many points to those that would be employed in actual practice, whereas the reverse of this should be the manner of proceeding, as the results would always be upon the safe side. It would appear that the object of an experimentalist is not to obtain the strength of a fair average specimen of the material under test, but to procure a result as high as possible; not to demonstrate what the material will withstand under the ordinary conditions of practice, but what it is capable of withstanding under the most favourable circumstances in which it could possibly be situated. It is this that has led among practical men to so great a distrust of the results of experiments, and to their placing so little reliance upon tables prepared expressly for their guidance and reference. They do not for a moment deny that those results are true for the experiments in question, but they do deny, and with reason, too, that they are, therefore, necessarily true for conditions other than those which attended their own production. The foundry at Indret, upon an emergency, can turn out at one running nearly 100 tons of metal, but a third of this is the usual amount. In a future number we shall revert to this subject, and give some particulars respecting the casting and treatment of steel, and the manufacture of boilers at this establishment.

CONVERSAZIONE OF THE INSTITUTION OF CIVIL ENGINEERS.

IN resuming our observations upon the interesting exhibition at the Institution of Civil Engineers last week, we will first notice a selected collection of samples of fractured materials of various kinds, which was sent by Mr. Kirkaldy, but to which, for want of space, was assigned a somewhat inconspicuous position. There was a portion of the broken cast-steel crank shaft of the Peninsular and Oriental Company's screw steamship "Jeddo," manufactured by Krupp, of Essen. It had been cut up into specimens and tested to ascertain the mechanical properties of the steel used. Besides these and a number of other specimens illustrative of the application of pulling, thrusting, bending, and twisting strains, Mr. Kirkaldy exhibited his patent indicator dial used with his testing machine for ascertaining the change in form of articles during experiment, extension and set under pulling stress, depression and set under thrusting stress, deflection and set under bending stress, distortion under shearing stress. He sent also four modifications of his patent micrometer, for ascertaining minute differences in measurement or dimensions. It is specially applicable for testing and other experimental purposes, and may also be used in various manufactures where great accuracy of measurement is desirable. The subject of strains reminds us of an ingenious method, devised by Mr. Airy, of ascertaining the tensile strains upon bars or rods by the musical note emitted by them when struck. A model of a bow-and-string girder illustrated the system, in which the members of the girder are represented by pieces of wire, which are weighted to a certain degree of tension, when they are struck to give the musical sound. A wire of similar length to the member is strained in a separate frame until it emits a corresponding note to that in the girder; the weight being taken, the strain is arrived at. When we have said that this method of taking strains is ingenious, we have summed up its merits.

Messrs. De Bergue and Sons exhibited a model illustrating an improved mode of transmitting the power of the locomotive engine to the wheels of the tender, converting them all into driving wheels; as also, where need be, the wheels of one or more of the carriages of a train, for the purpose of obtaining greater adhesion with a minimum weight on any of the wheels, so as to diminish the great wear and tear of tyres and rails, and facilitate more rapid starting and stopping without skidding. A coloured drawing illustrated the application of this system to a 4-wheel locomotive and 4-wheel tender, so as to constitute an engine with eight driving wheels, with short wheel base for quick curves. The dimensions and main particulars of this engine are as follows:—Length of fire-grate, 4ft. 9in.; width of ditto, 3ft.; grate surface, 14sq. ft.; length of tubes, 11ft.; interior diameter of tubes, 1¼in.; tube heating surface, 800sq. ft.; heating surface of firebox, 60sq. ft.; total ditto, 860sq. ft.; diameter of body of boiler, 4ft.; working pressure, 130lb.; thickness of plate of boiler, 7-16in.; diameter of cylinders, 16in.; length of stroke, 24in.; wheel base of engine, 9ft.; ditto, tender, 8ft.; diameter of wheels, 4ft. 6in.; number of coupled wheels, 8; weight of locomotive working, 23¼ tons; ditto of tender ditto, 19 tons; adhesion of locomotive (at one-sixth of weight), 3 tons 18cwt.; adhesion of tender, 3 tons 3cwt.; total adhesion in dry weather, about 7 tons; tractive force, at 65 per cent., 4 tons 3cwt. Adjoining Messrs. De Bergue's model was a novel arrangement for coupling the wheels of locomotives and tenders and locomotives to carriages by Mr. Livesay, and intended for mountain and other railways having steep gradients and sharp curves. The object of the inventor is to decrease the present excessive load on the driving wheels of locomotives by coupling the driving to the bogie or radial wheels, or to those of the tender, and when necessary to those of the next van or carriage, and thus to add considerably to the tractive power of the engine. The coupling consists of endless bands, which in practice are made of india-rubber and steel wire, and are perforated with a series of holes which are protected by steel bushes or eyelets. These bands work over cylinders on which are studs taking into the holes in the bands. The bands are from 12in. to 20in. wide, and from ⅜in. to ⅝in. thick, according to the power of the engine, and are said to be equal to a strain of from thirty to fifty tons, although in practice they will not be liable to more than five or six tons. Except in very rare instances it would not be found necessary to extend this coupling arrangement beyond the tender, first van, or carriage of a train. This amount of extra adhesion, says Mr. Livesay, would be fully equal to the cylinder power.

Mr. Dodds, of Rotherham, sent some samples of his steeled rails, which are offered as an alternative to those who complain of want of wear in iron rails and the expense of those of pure steel. Railway companies having recognized the value of steel rails, but having intimated that unless the price could be kept within a few shillings of the cost of iron, however valuable the rails, they would not adopt them, Mr. Dodds set to work to meet

Digitized by Google

these views, and has taken out several patents for making a more durable rail at the smallest possible extra cost. His first patent was simply to convert the surface of rails into steel, by an arrangement of furnace and mixture of carbonaceous fuel, which acted more rapidly at a lower heat than the process used by steel makers for producing blister steel. But he never supposed that rails so treated would be made more tenacious, that inferior iron would be changed to a first-class quality, nor that unsound rails would have their imperfections remedied. However, he found that a hard and more durable surface was produced, but with the exception that no blisters were made, these surfaces had the imperfection of blister steel, viz., brittleness. Mr. Dodds's latest improvements not only include a process of converting, but a peculiar arrangement for rolling or hammering after conversion, whereby the surfaces are rendered more tenacious, and the body of the rails are improved in fibre. These rails are said to be superior to cast steel, for the reason that durability against wear and tear is as their degree of hardness. Cast steel is homogeneous, and if hardened would be hard all through, and therefore brittle—if kept soft enough to be tough, the wearing qualities are reduced. Steel-surfaced rails (made by this improved process) have not this disadvantage, for the surfaces can be hardened or tempered to any required hardness, and still retain the ductility of the iron body. These rails are also superior to steel-surfaced rails made by welding a steel top on an iron rail, for no mechanical combination can be made with certainty; the expansion and contraction of the materials differ, and the rolling of the trains has a constant tendency to separate the two, as experience has shown. By Mr. Dodds's method, however, there is no defined line between the iron and steel, and it is an impossibility to separate them, due regard being had to the quality of the iron used, as good steel can only be made from good iron. These rails are produced at a cost midway between steel and iron rails, and, therefore, offer special advantages in an economical point of view.

The use of locking gear in the working of switches and signals at station yards and junctions having recently been rendered compulsory by the regulations of the Board of Trade, it has become a serious necessity to railway companies, proposing to open new or to alter existing lines, to procure apparatus fulfilling the conditions as to safety and efficiency required by the Board, and at the same time not show a disproportionate outlay compared with other items of expenditure. To meet this point, we find in the "economical switch and signal locking levers" an arrangement which, whilst not attempting to rival the costly and complicated machinery suitable for crowded metropolitan junctions, will yet ensure a reliable and safe protection amply sufficient for any ordinary traffic. In this arrangement of locking gear, which is manufactured at the Viaduct Works, Crumlin, it is impossible to move the switch lever until the signal levers have been first put to danger, and locked there. After this is done the switch may be moved as required, allowing shunting to be carried on without interfering with the signals. Neither can the signal levers be moved until the switch lever is made right, and locked to the main line. This prevents the liability of any accident arising from a mistake in working the signals. Another apparatus of this class which was exhibited is Mr. Cashin's patent safety switch levers. They consist only of three parts—the standard, handle or lever proper, and balance weight. The crank and oscillating jaw are substituted for the ordinary connecting rod and bell-crank. There appears to be no risk of accident arising from frost, or the various sources of danger and obstruction to which switch boxes are liable; and the whole being in view above ground, can always be kept in order. They work parallel to the rails, and can be fixed to a piece of timber or sleeper in a few minutes. In connection with railways we also observed one of Mr. Mallet's patent elastic hollow buckled plate sleepers, which had been proved with ten tons dead load placed on the chair. The deflection is stated to have been only 0·033 of an inch, and no permanent set occurred. It is astonishing what these buckled plates will stand. We must not here pass by without allusion to Messrs. Saxley and Farmer's excellent system of railway signals, although we purpose referring to them specially on another occasion.

Mr. H. Ormerod contributed a working model of his patent safety link for preventing those fatal accidents which so often arise from overwinding. This apparatus was fully described and illustrated by us on April 17 last, so that we need not now refer to it further than to say that it is simple in construction, effectual and certain in action, and not liable to get deranged or out of order. Messrs. Lambert Brothers sent one of Foster's ingenious contracting taps, which is especially adapted for screwing work in which the tap has to be withdrawn. This tap has many advantages; it saves considerable time, and does not take away the sharpness of the thread, as in the present solid tap, it not being necessary to unscrew the tap out of the work, as it is released and withdrawn at full speed without reversing the machine, thus doing away with the necessity of constantly running oil on the tap to keep it cool when unscrewing itself. It also dispenses with the necessity for reversing the motion in the screwing machine—the cause of much wear and tear. The body of the tap being made of steel does not wear. The cutting threads being of small size steel, a better quality of metal is ensured, the tap is consequently very durable under heavy work. This is proved by experience in the screwing department of Messrs. Lambert's Tube Works at Walsall, when upwards of 4,000 1-inch wrought-iron tees, or 12,000 holes, have been screwed by one tap without renewing the cutters.

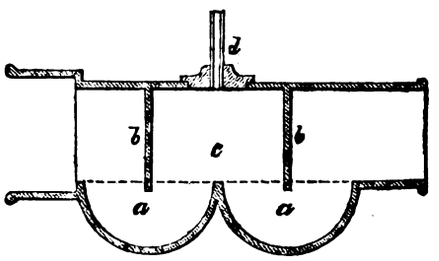
Messrs. Moreland and Son exhibited their improved method of constructing floors, which consists in fixing wrought-iron girders at given distances apart on the walls of buildings, and then placing between them on their lower flanges a number of wrought-iron bow-and-string lattice girders, and on the upper or curved surface of these laying corrugated iron throughout the floor. Concrete is then laid on the corrugated iron to the desired form and thickness, and sleepers, joists, and floorboards are then laid on the concrete in the ordinary manner. The ceiling joists are fixed on the lower part of the lattice girder, and are lathed and plastered in the usual way. This system of flooring is adaptable to all spans and positions required in ordinary buildings, particularly in large spans, and it is found to be more economical and much more rigid than floors constructed with rolled girders. Large spans may be constructed upon this principle without the intervention of main girders, as the wrought-iron girders are made of the greatest depth possible, being kept close to both floorboards and ceiling, thereby ensuring the greatest rigidity and strength with the least quantity of material. The air space which is included between the under side of the corrugated iron and the ceiling, being a non-conductor of sound and also of heat, renders the floor sound-proof and safer under the action of fire, either from above or below the flooring. The concrete being laid on the corrugated iron forms a natural arch, which is prevented from exercising any lateral thrust by reason of the bow-and-string lattice girders with the corrugated iron acting as permanent centering to the arch. This combination has been proved by a variety of tests to be the best and most economical disposition of the various materials composing the floor. Of the results of these tests—which include dead-weights and the impact of falling bodies—it will not be amiss here to say a few words. An arch was formed by laying a concrete of broken brick and gypsum on corrugated iron, No. 20 gauge, with 3in. flukes, supported by bow-and-string girders 8ft. long, 8in. deep in centre, and made of 1¾in. × ¼in. angles, 2in. × 3-16in. verticals, 1¼in. × ¼in. diagonals, and ½in. rivets, the whole resting between two wrought-iron girders 20ft. long, 16in. deep, 4in. × 4in. × ½in. angle iron, and tied together with tie rods 1⅜in. diameter, 1⅜in. ends. After standing twenty days, a cast-iron weight 12in. square on the face, 2ft. long, and 9in. square on the top end, and weighing 650lb., was raised 16ft. immediately over the centre of one of the bow-and-string girders, and allowed to fall on the concrete arch above it. On falling, the weight penetrated the concrete 4½in., and the elasticity of the bow-and-string girder caused it to rebound 10in. or 12in., and on falling again the lattice girder was further deflected. The corrugated iron after the impact was 1¼in. clear for 4ft. 3in. of the bow-and-string girder. The bow-and-string girder had the centre vertical bent and cracked, the diagonal broken, and two rivets securing the diagonal at top started. The application of dead-weight loads was also eminently satisfactory.

There remain but few things more to be noticed, amongst which comes Murray's brick-cutting table, which was exhibited by Mr. Middleton, of Southwark. These tables can be adapted to any steam brickmaking machines, and it is said that from 2,000 to 3,000 bricks can be made with each table per ten hours more than with any other cutting table at present in use. This is effected, not by increasing the speed of the stream of clay issuing from the die, but by avoiding stoppage and waste, as the clay is continually running, and not more than about one in twelve bricks need be thrown back. Twelve bricks are cut at a stroke, and the day's work, making the increased number of bricks, is done with less labour than is required for the smaller number of bricks with other cutting tables. The wires can be adjusted to cut bevel bricks to any angle as well as straight bricks, and the bricks cut are removed to the barrow without handling, which increases their value. No sand is used on the table, so that the wires and fustian are subject to very little wear. A common oil not exceeding 4d. per gallon in cost is used for lubricating, and a pint is found sufficient for 1,000 bricks. These tables have been used by Messrs. Kelk, Waring, and Lucas, the contractors for the Metropolitan Railway, with highly satisfactory results. Messrs. Forrester, of Liverpool, sent one of Gray's improved compressed air riveting machines, which have been in use for a lengthened period, and answer admirably for all ordinary classes of boiler, ship, girder, tank, or other riveting. The machine itself is quite portable, weighing only 28lb., and from the rapidity of its action it is stated that the recoil is scarcely felt by the man holding the machine to its work. The starting of the machine is effected in a simple manner, and is fully under the control of the man guiding the machine. The connection between it and the air compressing machine is by a flexible tube. An ordinary skilled labourer can do with it four rivets ¾in. diameter per minute, in straightforward work.

Mr. Edward Cottam, of Battersea, sent one of his "Interceptors," or patent effluvium traps, a section of which we give annexed. To prevent the entry of sewer-gas into the house, *a a* are hollows to form the water lute, *b b* two diaphragms, which form an intercepting chamber *c*, by means of which the foul air of the drain, forcing the lute, is caught and carried by a grating or pipe inserted in the lid *d* into the outer air. The same firm also sent a specimen of what they very properly term the "Humane" horse-shoe, by which the

Digitized by Google

horse can endure hard work without pain, and by the use of which his feet are found to last sound during his natural life. As the weight of the horse is mainly sustained by the crust of the hoof, so this shoe is designed to arm



that crust, and to preserve, although caulked, the true level position of the foot. The level caulking prevents that straining and waste of muscular power consequent upon continual slipping and rocking of the foot. Burning on the shoe to fit it destroys the hoof, rendering it brittle; this common and pernicious practice is entirely avoided, as the "Humane" shoes are made true and level by machinery, and can be better fitted cold. With this shoe, and by the system of shoeing, the patentee, Mr. Goodenough, states that horses recover from diseases arising from bad shoeing, viz., contracted feet, corns, sand or quarter cracks, thrush, springing of the knees, shrinking of the shoulder, &c. The efficacy of this shoe has been thoroughly proved in America; in New York alone, we understand that over 80,000 shoes are made weekly.

TESTING THE RUNCORN GREAT BRIDGE.

THE enormous girder bridge erected by the London and North-Western Railway Company over the Mersey at Runcorn is now practically completed, and on Thursday week was subjected to the preliminary tests of stability. The object of this great work is to carry a line of railway over the Mersey at this point, by which the Company will shorten the route from London to Liverpool by fifteen miles or so. Messrs. Brassey and Ogilvie are the contractors for the line, whilst Messrs. Cochrane, Grove, and Co., have undertaken the Runcorn Bridge, the execution of which they have entrusted to Mr. J. P. Ashton. The bridge was designed by Mr. W. Baker, the engineer-in-chief of the North-Western Railway Company, Mr. S. B. Wells being the resident engineer. The bridge is upon the trellis girder principle, and is nearly 1,000ft. in length, supported upon stone piers 167ft. in height from foundation level, and which rise 75ft. above high-water mark. The three central spans are 305ft. each. At each end of this great girder are several arches which carry the railway over the remaining portion of the river. There are three of these arches on the Cheshire side, and five on the Lancashire side, each having a span of 60ft. These are succeeded on each side of the river by a long viaduct ending in an embankment, with a gradient of about 1 in 120, until the level of the line at Ditton and Aston respectively is reached. Altogether, independently of the girder bridge, there are 97 arches, 65 being on the Lancashire and 32 on the Cheshire side. The arches of the viaduct have a span of 40ft. The width of the bridge is 38ft. over all, and 25ft. between the girders; and there is a footpath 6ft. wide on each side of the bridge. For the purpose of testing the bridge in the severest manner, sixteen locomotive engines, each loaded to a weight of 15 tons, were sent from Crewe. Two engines were first sent over, then four, then six, afterwards eight, and finally the whole sixteen. Eight engines were then placed on each line of rails between two piers, besides which there were 90 tons of material in the footways, so that, including the girder itself, about 2,000 tons of dead weight was suspended between two points 300ft. apart. The two trains of engines were then run backwards and forwards at full speed without perceptibly affecting the steadiness and stability of the structure. The results, however, as registered by the gauges, were a deflection of barely an inch and a quarter, whilst the permanent set was only three-eighths of an inch. This result must be highly satisfactory to all engaged upon the work, as it far exceeds what was anticipated. The first stone of this bridge was laid on April 12, 1864, and the last rivet was driven on February 14 last. The estimated cost of the bridge was £250,000; but this, as a matter of course, has been somewhat exceeded. Some minor works on the line still remain for completion, but the whole is expected to be ready for traffic in the course of a few months.

ENGLISH AND FRENCH LENSES.

THE facts we mentioned a week or two ago, that the best lenses of the French opticians, although as good as the best English lenses, average less than half the price, and that the photographic journals have omitted to make known this truth to their readers, necessarily somewhat awoke the consciences of the latter journals. The "Illustrated Photographer," in a letter it publishes on our article, says:—"It is quite possible to get from a French optician a lens in all respects equal to one by the best of our English makers, and that at considerably less cost. But it is a 'toss up,' or, rather, ten to one against your getting really a good one. They turn them out as a bricker does his clay out of the moulds; they put them into flimsy brass mounts, and 'there you are' for the market. I should do injustice to Maugey, Lerebours, and Hermagis, of Paris, whose instruments I know, were I not to say that some of their best compound (portrait) lenses are quite up to the mark of our best English optician, Mr. Ross, and to that of Voightlander."

As this paragraph admits that particular French opticians do turn out lenses as good as the enormously high-priced ones sold sometimes in England, and at much less cost, so far its statements are authentic. But the statement that the French lenses of the best makers have bad brasswork is not true, for Darlot, whose lenses carried off the first prize against all-comers at the Paris International Exhibition, turns out brasswork mounts which the merest tyro can see at a glance are in most cases superior to the mounts of the best English lenses. Again, the percentage of bad lenses sold by the best Parisian opticians is not higher than the percentage of bad ones sold by the best English opticians. Lastly, the "Illustrated Photographer" says that Mr. Ross (the optician who advertises most in its pages) is the best lens maker in London. The "Photographic News" praises Mr. Dallmeyer (who advertises most in its pages) infinitely more than any other optician. Whence this discrepancy? And if both these journals think they are right on the point, why do they not test the lenses against each other, state the results in figures, not opinions, and then go into the question of price, as compared with French lenses.

The editor, or one of the editors, of the "British Journal of Photography," has an intelligent knowledge of the principles of construction of lenses, and his reply to our article is amusing. The facts being too strong, he cannot deny them directly, so he asks a string of questions, which he does not answer, and thus flings doubts over our statements by implication. He speaks of the difficulties of making lenses, which we do not deny, but these are as great in Paris as in London. He says:—"Photographic lenses are not made out of window glass, but out of discs of optical glass, which, even at the glass manufactory, and while as yet untouched by the optician, costs a much higher price than is usually imagined. A good lens must be free from flaws and imperfections: and as striæ in the glass is one of the imperfections most difficult to eliminate, it naturally follows that for pure glass a price must be exacted proportionate to the expense and difficulty encountered in its production." Now, nobody knows better than the writer of the foregoing that a halfpenny per pound extra price will buy window glass without striæ. He also knows that inferior optical glass which will not do for the telescope will do for photographic lenses, as, from some source or other, it is an advantage in the latter to have a little "diffusion of focus." A lens which produces a perfectly sharp image in one plane only is bad in photography. Moreover, we have seen a landscape lens made out of common plate window glass, which worked well in photography.

A more important subject than this to English photographers could not be chosen, for, unfortunately, information how to make cheap homely lenses, such as we published a few weeks ago, is never given in metropolitan photographic literature. A corrupt journal, directly under the thumb of an advertising tradesman, would be of course unable to speak the truth on these points, and we have no direct knowledge that any photographic journal of this kind is published in London. Nevertheless, silence on the fact of the enormous differences in the price of English and French lenses of the same quality is a marked feature of London photographic literature, and now that the serious omission has been publicly brought under the notice of the managers of these journals, we hope not one of them is so afraid of free discussion as to decline to quote the whole of the two articles we have written on the subject, without abbreviation or alteration. There is no doubt that the matter is so important to their readers that the space would not be wasted; moreover, the fact of making the quotations in full, will show that the editor so quoting is not afraid to have the back numbers of his periodical examined by his subscribers, to see whether those who advertise most largely have uniformly and systematically received most editorial praise of their goods.

Nobody would be better pleased than ourselves to see them adopt this plain and straightforward course, thereby enabling their readers to see, unabridged and unaltered, what we say on one side, and in separate articles what they say on the other. There are photographers in London who think one or other of the journals dare not stand this test, and will make any mortal excuse to escape from it; so as this suspicion may be most unjust to honourable journalists, those editors will, of course, be delighted to seize this fair method of ventilating a subject, which, although of great interest to their readers, they have hitherto chanced to overlook. The best lenses of the best French opticians are quite as good as the best lenses of the best English opticians, the only difference being that the former are about half the price of the latter. A French optician, with his fair-priced lenses, carried off the first prize against all-comers at the Paris Exhibition. Therefore, we think it would be a great protection to photographers if an establishment were started in London, which would test lenses for anybody at a moderate fee, and state the results in figures, so that lenses shall henceforth get a reputation on their own merits.

WORKS IN IRON.*

WE have of late observed the growing tendency of manufacturers and others desiring to place before the public the various

* "Works in Iron." By ANDREW HANDYSIDE and Co., Britannia Iron Works, Derby and London. E. and F. N. Spon, 48, Charing Cross. 1868.

Digitized by Google

works in which they are specially engaged, to adopt a style of conveying information which almost brings their books within the scope of scientific literature. The latest production of this kind which has been brought under our notice, is that of Messrs. Handyside and Co., of the Britannia Works, Derby, who, no matter what commercial object may be their aim, really deserve credit for giving the public a vast amount of practical information on some of the most important points connected with ironwork. The Britannia Works were established in the early part of the present century as an iron foundry, and soon became noted for the superior quality of what are known as "Derby" castings. In time, these works came to turn out every description of wrought as well as cast iron work, including steam engines and machinery of various kinds. The volume now under notice is a remarkable production of its class, as, without specially professing to do so, it forms a useful record of a number of the most interesting public structures both at home and abroad. Besides this it enters upon the questions of the strength, quality, and application of various kinds of mixtures of iron in an eminently practical manner. Its professed object is to form a useful book of reference to all those at home or abroad who may be interested in engineering or other ironwork, and it succeeds admirably in accomplishing this object, inasmuch as it gives in a concise form a large amount of information which cannot fail to prove useful to engineers at home or abroad. And not only to engineers alone does it address itself, but, in fact, to all those who, away from home, cannot have access to the usual source of information. Its illustrations are in all cases those of works actually executed, and not merely cut-and-dried representations of what can be supplied. And, what is more, correct views of the various works are given by means of photography, the aid of which has been judiciously obtained.

Having indicated the aim and object of Messrs. Handyside's book, let us look into it and see how these have been carried out. It is divided into three main sections, treating of three distinct classes of work in all their detail and variety. In the first place, we have constructive ironwork, including roofs, bridges, and buildings. Next, we have steam engines, machinery, and foundry work of all kinds; and, thirdly, ornamental ironwork. Under the first head are some useful remarks upon the quality of iron, embodying the results of practical experiments and suggestions for aiding a proper selection of the material. Bridges and girders of various kinds are next noticed, numerous examples being given of structures upon the several principles now adopted in engineering practice which have been made and erected by Messrs. Handyside. And it is not merely a descriptive account which is presented to us; we have also much information about the forms of the several members of the girders and the iron suited for each purpose. Amongst the examples of bridges illustrated will be found one over the River Wye, at Hay, in Brecknockshire; another for the Queensland Railway, in Eastern Australia; a railway bridge at Whitney, Herefordshire; and another over the Avon, near Bath, all of which have been turned out at the Britannia Works. We specially notice Handyside's colonial bridge, which is admirably suited for new colonies and foreign countries, where transport is difficult, and skilled labour scarce and expensive. It is so designed that there are no pieces of excessive size or weight, and the mode of erection is simple and speedy, no riveting being required. Iron roofs are also amply considered, those of the Agricultural Hall, the Inns of Court Hotel, the Broad-street Terminus of the North London Railway, and the Amsterdam Station of the Dutch Rhenish Railway being conspicuous. The average weights and prices per square of 100ft. are given for various other constructions of roofing, of small as well as of large span. Following the roofs are particulars of iron buildings, in which Messrs. Handyside have had much experience both as regards plain and ornamental structures.

In the second division we have some useful hints with respect to steam engines and machinery in general. In this department Messrs. Handyside's specialty appears to be colliery winding engines, of which a pair have recently been erected by this firm at the Moira Colliery, Leicestershire. These engines, which are well illustrated, are horizontal and non-condensing, and are coupled to one crank shaft. The cylinders are 30in. in diameter, making a stroke of 5ft., and together exert a combined force equal to about 150-horse power. We shall not further describe this engine now, although disposed to do so, as we hope shortly to place full particulars and drawings of it before our readers. In the third division of the work, we have iron presented to us in another form—the ornamental—in which condition it is largely utilized for conservatories and such-like buildings. The most recent example executed at the Britannia Works is the winter garden in the new infirmary at Leeds, an elegant structure, and which was recently opened. An earlier, but more familiar, example is the splendid conservatory in the Royal Horticultural Gardens, at South Kensington, of which we have a fine photograph. This is one of the largest conservatories in the world, being 265ft. long, 96ft. wide, and 75ft. high in the central aisle. Besides these and many other more prominent examples of ornamental ironwork, we have a collection of smaller items, from fountains and vases down to pillar letter-boxes and railings. We have now said more than enough to show that we have no ordinary price list or illustrated catalogue here. Much time and money must have been expended in producing such a work. Brains, too, have not been wanting, and in this respect we believe we are right in ascribing to Mr. Ewing Matheson—the London representative of the firm—the conception and literary execution of the work. It reflects great credit on him, as do the structures it illustrates on the proprietors of the Britannia Works. The publishers, too, have done their part well, and the book is turned out in a highly creditable manner.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

AN IMPROVEMENT IN GALIBERT'S APPARATUS—ZIRCONIA IN THE OXYHYDROGEN FLAME—THE PASSAGE OF HYDROGEN THROUGH PLATINUM AND THE DISSOCIATION OF WATER—ARTIFICIAL SAFFRON—LUBRICATING OIL FROM COCKCHAFERS.

THE apparatus of M. Galibert, which allows the wearer to penetrate into poisonous atmospheres without danger, has been recently improved by the inventor. As our readers will remember, while a communication is kept up with the external atmosphere by means of a tube, the wearer of the hood is compelled to rebreathe the air expired from his lungs. Thus the air became overcharged with carbonic acid, and the hood could not be worn for any length of time. M. Galibert has now added a receiver into which he puts potash, by which the carbonic acid is absorbed, and the expired air is again made fit for respiration. This is a great improvement, and the apparatus is perfectly calculated to prevent those fatal accidents so frequently occurring in breweries, sewers, and old wells; and also to enable men to rescue the sufferers from coal mine explosions. M. Galibert's apparatus should be kept in readiness at all establishments where risks of the kind are possible.

The use of the oxyhydrogen flame for illuminating purposes is extending, so we may record the observation of M. Caron, that the maximum of light is only obtained when hydrogen is used in excess of the proportion necessary to form water. He has also made another observation more interesting than useful at present, and that is that a much more powerful light is obtained when zirconia is employed in place of magnesia. Zirconia is unfortunately rare and expensive to-day, but it may some day become cheap, and M. Caron's discovery may prove of value. In the mean time he suggests that it is not necessary to use a cylinder entirely of zirconia, but a foundation may be made of some other material, the outer part being composed of the rarer earth. Zirconia, he tells us, is completely unchangeable in the flame, and will last for ever.

Mr. Grove, as Dr. Odling recently mentioned at the Royal Institution, first showed that water may be decomposed by passing steam through a platinum tube intensely heated by the oxyhydrogen flame. M. Deville has recently shown that under such circumstances the hydrogen passes through the platinum while the oxygen is retained in the tube. M. Deville seems to have been repeating some of the experiments of Mr. Graham, with the view of supporting his own theory of dissociation.

What is artificial saffron? We must confess to ignorance on this point, but as the article is in actual use as a colouring material for vermicelli, macaroni, and possibly other things, we feel it our duty to inform our readers that it is a dangerously explosive substance. It is imported into France from Germany, and we read that a few weeks ago a workman was engaged in opening a tin of it when the contents exploded and burnt the man so severely that he died. We might suppose it to be some picric acid compound, but all these preparations we know are intensely bitter, and little likely to be used for colouring alimentary substances.

Everything in nature no doubt has its use; but we should never have supposed that cockchafers were intended to yield lubricating oil, which, we read, is now extracted from them in France, where they are this year unusually abundant. How the oil is extracted we are not told.

THE ROYAL HORTICULTURAL SOCIETY.

THE great flower show of the season was opened on Tuesday last, at the Royal Horticultural Gardens, South Kensington, and was attended by a very numerous and distinguished company. The display of azaleas, heaths, and pelargoniums was unusually fine, whilst the show of rhododendrons under the tent was magnificent. These plants are now at their best, and form a splendid and striking show. The following are the principal prizes awarded by the judges:—For nine greenhouse azaleas, distinct, Messrs. S. Glendinning and Son, nurserymen, Chiswick, £15; and Mr. S. Carson, gardener to Mr. W. R. G. Farmer, Nonsuch-park, Surrey, £10; for nine roses, distinct, Mr. W. Paul, Paul's Nurseries, Waltham-cross, £12; for nine show pelargoniums, distinct, Mr. J. Fraser, Lea Bridge-road Nursery, £10; for twelve exotic orchids (open), Mr. C. Renny, £15; for ten exotic orchids (nurserymen), Mr. B. S. Williams, £12: for twelve stove or greenhouse plants, Mr. B. Reid, £15, and Mr. J. May, £12; nine fine-foliaged stove or greenhouse plants, distinct, including variegated plants, Mr. S. Fairbairn, The Gardens, Sion House, Isleworth, £10; for twelve stove or greenhouse ferns, Mr. B. S. Williams, £10.

IMPROVED SLIDE RULE.

MR. JAMES NOBLES, an engineer, of Fitz-William-street, Sheffield, has greatly improved the engineers' slide rule by the introduction on it of gauge points for obtaining the weight of steel and wrought iron in square, round, octagon, and triangular bars, in inches, 8ths, 16ths; also in French lines and millimetres. On the back of the rule is a table of decimal multipliers, for obtaining the weight of steel in figures, in inches, 8ths, 16ths, 32nds, 64ths; also in French lines and millimetres in bars of the above sections. The engineer can with this rule obtain his weights without the trouble of calculating decimals. These, and other points of usefulness, render these rules—one of which is before us—a valuable acquisition to the engineer and mechanic, who owe Mr. Nobles thanks for helping to simplify the work of calculation.

DURING the past week thirty wrecks have been reported, making for the present year 955.

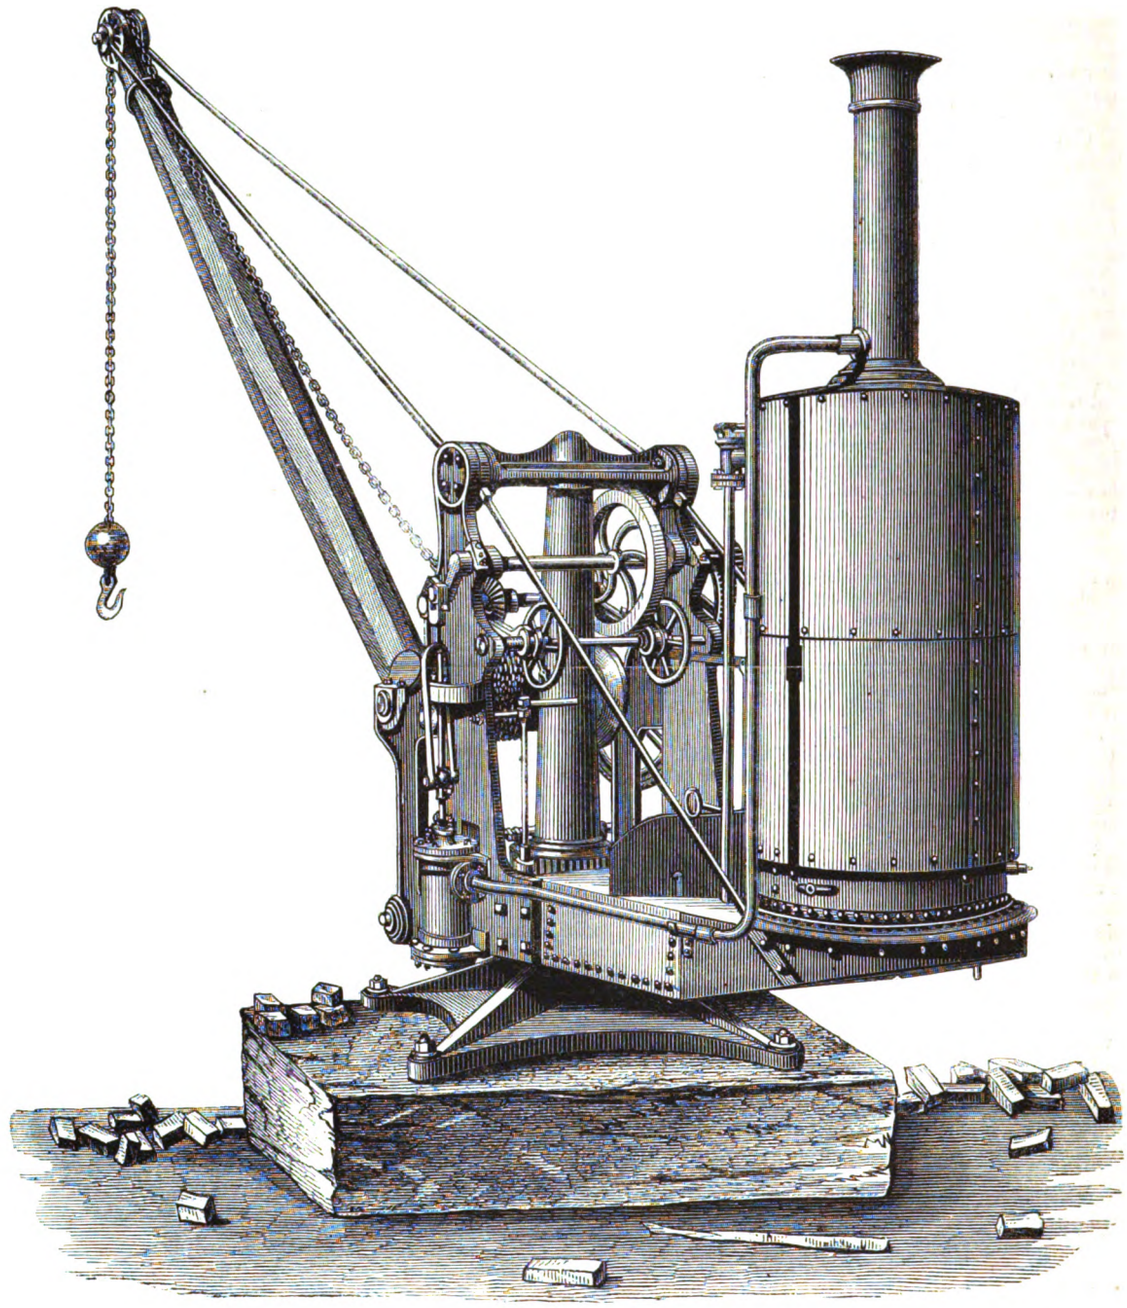
STEAM CRANE.

BY THE DALLAM FORGE COMPANY.



STEAM CRANE.

THE steam crane chosen for illustration above is one of several made by the Dallam Forge Company, Warrington. It is 15ft. high and 15ft. radius, and is hung upon a cast-iron central pillar firmly fixed on a massive sole plate, which is secured to a foundation by the usual holding-down bolts, and which has on it a turned race for the roller at the gib foot to travel upon. The crane can be swung completely round by means of a worm, carried by the crane waist, gearing into a worm wheel keyed on to the central pillar, the boiler and water tank, which is under the foot-plate, serving as a counterbalance to the load. The steam cylinder, of 5in. diameter, and with 10in. stroke, is fastened on to the cheek of the crane working the gearing for hoisting and swinging in either direction by means of conical clutches thrown in and out of gear by two hand-wheels working on a screwed bar, the brake for lowering being worked by the foot. The feed pump is worked from an eccentric keyed on to the crank shaft of the engine. With a working pressure of 50lb. the crane has discharged between 60 tons and 70 tons per hour in 20cwt. and 25cwt. lifts. The boiler is an ordinary vertical firebox boiler, the draught being accelerated by the exhaust steam passing into the chimney. It is fitted with steam and glass water gauges, safety valve, spring balance, man and mudholes, and blow-off cock. The crane is also fitted on a strong cast-iron carriage with four wheels for either road or rail.

IMPROVEMENTS IN FANS.

MR. C. SCHIELE, of Frankfort-on-Maine, whose name is well known in connection with turbines and similar apparatus, has recently made some important improvements in fans. In these fans the strain of the strap, axis, and the tremour caused by the revolving of the vanes, is confined to one casting—a pillar, which is fixed by its bottom plate securely to the foundation. The casing in which the vanes revolve, therefore, becomes a mere air-chamber, which is made of very light plate. This is so mounted on the bearing of the pillar that it can be turned round to direct the discharge-opening as may be desired, and then fixed by a set screw. There are only about four light plate-vanes, square, as of old, which, however, instead of throwing the air out against the outside casing, producing a terrible noise, or receiving checked air back between them, causing a great waste of power, have a concentric channel formed round them, in which the air thrown out by the vanes continues revolving, and is prevented from flying out by its centrifugal force. This ring is wider than the vanes, and so much air only escapes as is required at the time, and is propelled forward through the casing to its destination. This ring is at some distance round the vanes, but its sides are provided with flanges, which have an inside radius about equal to that of the vanes, thus ensuring the confinement of the revolving air until required. The suction opening is in the centre, at the front of the casing. Mr. Schiele promises us drawings and description of this apparatus, which we hope, in course of time, to place before our readers.

MANUFACTURE OF PRINTED TAPESTRY CARPETS.

IN the manufacture of printed tapestry carpets it is customary to use straight threads of warp in the back or body of the fabric, which are called "dead," for the purpose of filling up the interstices between the lines of the real or binding warp, and for supporting the pile warp. This dead warp is usually made of linen threads dressed smooth with size, and having generally three threads in each spac between the dents of the reed, the effect of using

Digitized by Google

his smooth sized dead ward of threads being to make the carpet comparatively thin, hard, inelastic, and cold. We have before us, however, an invention which has been patented by Mr. William Wood, of Monkhill, near Pontefract, and by which the carpet is made thicker, softer, more elastic, and warm. It consists in making the dead warp wholly or partly of certain other materials in suitable forms and combinations.

In the first place, the dead warp is made of yarns composed wholly or partly of silk obtained from cuttings and rags of woven fabrics wholly or partly of silk, which are torn up, and either alone or combined with any other suitable fibres are formed by the usual or other convenient processes into yarns of suitable size and strength. In the next place, the dead warp is formed of yarns made wholly or partly of wool, hair, or such-like animal fibres, either new or obtained from cuttings and rags of woollen, union, or linsey fabrics and spun waste, and new or old carpeting. These also either alone or mixed with other fibres are formed by convenient processes into suitable yarns. In the formation and application of these improved yarns for dead warp Mr. Wood prefers to twist and size the yarns to such extent only as will enable them to be woven properly, that is, he preserves as much softness and elasticity as possible in the dead warp, and to enable this to be carried out with a minimum of twist or size, he sometimes "doubles" or intertwists the yarn of silk, wool, or animal fibre with a linen or other strong thread, so as by binding them to assist the weaving of soft or short fibred yarns, and coating the thread with cementing matter.

THE APPLICATION OF TOWN SEWAGE TO GENERAL FARM CROPS.*

By THOMAS CARGILL, C.E., B.A.

IN bringing before you this evening the subject of the present lecture it is unnecessary for me to enlarge upon the importance to which it has attained, the increasing interest which is attached to it, and the serious consideration and attention it claims at the hands of the whole community in general, and of the agriculturist in particular. Still less occasion is there to deduce arguments in favour of the utilization and application of sewage, either from the pages of Holy Writ or from the examples afforded by the Japanese, Hindoos, Chinese, or similar semi-civilized nations. From whatever point of view the subject may be regarded, whether sanitary or otherwise, the utility of it has been acknowledged from the earliest times, and the absolute necessity of it has now become universally apparent. To the question, "What is to be done with our sewage?" there is but one answer, "Apply it to the land," but to the question, "How to apply it?" or, rather, "How to apply it in the most economical and remunerative manner?" the answer is not so simple, owing to the fact that it has not received that thorough investigation which it demands, and which must be eventually accorded to it. The reason of the want of information generally felt with respect to the application of sewage to land, and, consequently, of the unwillingness of parties to embark in projects of this nature, is due to many causes. Of these the principal, undoubtedly, is that sewage has never hitherto been regarded by us in its proper light. It has always been considered as a nuisance, as a thing to be got rid of somehow and somewhere at any price, and men continued to shun and avoid the evil, instead of grappling with it, until it assumed a character so alarming and proportions so gigantic that at last self-defence urged them to adopt measures calculated to mitigate what was fast becoming a national scourge. Even at the present time this is the view of sewage entertained, most unfortunately, by the majority of local boards and corporate authorities, who, as a rule, have accomplished little or nothing regarding the disposal of their town sewage. At the same time, it is idle to imagine that we shall ever fully appreciate the true value of sewage or benefit by the advantages within our reach, until we esteem them properly, and regard as an invaluable blessing what has previously been looked upon almost as a curse.

Town sewage, in the general acceptation of the term, and in which sense it is here employed, is composed of the numerous and various elements constituting the contents of sewers, including the liquid and solid excrements of human beings and animals, the waste water and refuse from dwellings and manufactories, and the ordinary drainage of the streets. In alluding hereafter to the application of sewage, it will be supposed to be taken direct from the sewers and applied to the land without undergoing any previous process of disinfection or deodorization. I the more particularly call attention to this statement, as I consider it essential to the real economy and ultimately remunerative character of the system adopted. Not a single one of the many processes undertaken with reference to modifying the condition of sewage has been attended with even a partial success, and there is not the slightest doubt but that it must be taken pure from the sewers to impart the greatest benefit to crops. At Tottenham, Leicester, Birmingham, and Manchester various disinfecting and deodorizing schemes have been tried, but which have all resulted in complete failure. At one place 4s. per ton was barely obtained for that which was expected to realize £4; while at Birmingham scarcely 6d. per ton could be got for the solid residue left after deodorization and evaporation. Similar results attended the first operations at Croydon, where a most expensive and elaborate system of filtration was carried on for a time, in order to prevent the pollution of the River Wandle. It must not, however, be understood that in some instances, as at Norwood, subsidence tanks can be altogether dispensed with. They are rendered necessary whenever the sewage is conveyed over a short distance in pipes laid at sharp gradients, the flow in that case being too rapid to allow of the deposit of the heavier particles. As an example of an opposite character, we may take the Lodge Farm, at Barking, where subsidence tanks are not required, the sewage being conveyed for several miles in the Metropolitan main sewers. During its journey it not only deposits many of its heavier constituents, but some of them become dissolved and churned up in the general mass of fluid. At the occurrence of a considerable rainfall the sewage at Barking always comes over muddier and stronger than at other times, plainly showing that the violent rush of water carries along with it in suspension the heavier particles deposited upon the bottom and sides of the sewers during the ordinary flow.

Having defined the meaning of the term "town sewage," the next step is to ascertain its exact composition and the chemical constituents it possesses. These will vary with the habits of different populations accordingly as wealth or poverty predominate; with the character of the refuse, the rate of the water supply per head, the nature of the soil, the rainfall, and the materials of which the roads and streets are formed. Among the valuable constituents of town sewage the principal are, firstly, nitrogen, which exists partly in the form of ammonia and partly as organic matter; secondly, potash; thirdly, phosphoric acid and phosphates; fourthly, organic matter, which is found in two conditions, one soluble and the other insoluble, the latter remaining in a state of mechanical suspension. In one gallon of average sewage the proportions of the above ingredients are, in grains—nitrogen, 6·7; phosphoric acid, 1·8; potash, 1·1; and organic matter, 30. The total quantity of solid matter in one gallon varies considerably. Taking an average of numerous analyses I have found it to be 131·88 grains; but the only reliable method of ascertaining the composition of any particular specimen of sewage, or, in fact, of any manure, is to have it specially analyzed, which can now be done by competent chemists at a very moderate charge. Notwithstanding that the composition of sewage is dependent upon so many fortuitous circumstances, yet it may be accepted with perfect safety that there is no description of town sewage that cannot be profitably applied to land so far as the land itself is concerned. This has been satisfactorily ascertained in the case of the Manchester sewage, which is nearly as black as ink in colour. The question of the application of sewage proving profitable in a pecuniary sense depends altogether upon the proportion which the necessary outlay and working expenses bear to the result obtained. A capital that would insure a good return upon works laid out to sewage 500 acres would be totally unremunerative if expended upon 80 or 90 only. As sewage contains a sufficient amount of ingredients to render it a valuable fertilizer for any crop its commercial value is an item of great importance. Without entering into the details of the facts and experiments undertaken at different times to determine the exact commercial or market value of town sewage, it will be sufficient to state that the average of ten different estimates made by the first authorities makes it equal to 1·48d., or a fraction less than a 1½d. per ton, which for all practical purposes may be safely quoted as its value. It must be borne in mind that this represents the value of the fertilizing constituents in town sewage compared with guano, which is assumed as the standard, and which has been taken in the above estimate to be worth £12 per ton. Experiments have proved beyond a doubt that town sewage could be profitably applied by the farmer if it were worth only ½d. per ton, instead of three times that amount. Another method of estimating the value of sewage, which is a more convenient one for calculation, is to rate it at so much a head of the population. The sewage commissioners arrived at the conclusion that the standard value was fairly represented at 8s. 4d. per head, and there is no doubt but this might be correctly assumed as the basis for calculating the returns likely to be realized by the application of town sewage to agricultural purposes. The highest value at which it had been estimated at per head is 16s. and the lowest 6s.

As it is from the example of the past that we regulate the present and provide for the future, I cannot do better than briefly to direct your attention to what has been already accomplished by the application of sewage to general farm crops. Edinburgh, by reason of the length of time during which sewage irrigation has been carried on there, has a prescriptive right to priority, more particularly as the results obtained, in comparison with those at other places, present the greatest pecuniary value. A large tract of land, consisting of almost pure sea sand, hardly worth 2s. 6d. an acre, has been converted, by the application of town sewage in large quantities, into fertile fields worth £40 per acre. Five crops of grass are cut annually, averaging forty-seven tons to the acre, and selling for a price so high as £40 occasionally, but yielding a fair average of £27. At South Norwood the greatest crop of Italian rye grass ever obtained was sixty tons to the acre, and last year the average was fifty tons. Croydon is always quoted, as it justly deserves to be, as a most successful instance of sewage irrigation, although, at the same time, it possesses many advantages with respect to site and the natural levels of the ground not always to be met with in other districts. The average number of cuttings is four, and the produce of meadow grass is equal to about thirty tons per acre, which sells for £25. The rye grass yields thirty-five tons to the acre, and sells for £30. These returns, heavy as they are, have been surpassed by those realized at Lodge Farm, Barking, where the heaviest crop obtained in one year from one acre of rye grass was sixty-one tons. The greatest number of cuttings, I was informed by the manager, was eight, and the average six. As an example of the extraordinary rapidity of the growth of the plant, it may be mentioned that a height of 30in. was grown in as many days. The grass is sold on the ground at the rate of £1 per ton. In the neighbourhood of Chelmsford, where the quantity of sewage is very limited, and the land much subject to flooding, six cuttings of rye grass were obtained per acre, weighing nearly fifty tons. The sewage works at Bury have been scarcely a year in operation, but ten and a-half tons of rye grass was the yield per acre of the first crop cut. The Edinburgh meadows, which have been irrigated with sewage, in one way or another, for a couple of centuries, are a proof that the continuous application of it to land is not injurious to its productive powers, more especially when the deposit accumulated during the whole of that period has not amounted to more than half an inch in thickness. There is an enormous waste incurred in the application of the sewage at Edinburgh, chiefly owing to the fact that there is a superabundant supply and nothing to pay for it. Instead of being injured and deteriorated land improves in its productive qualities by successive annual treatment with sewage. This has been proved by the results obtained both at Barking and Worthing. The crop of rye grass, cut at the latter place during the first year of the application of sewage, yielded barely twenty tons to the acre, while those of last year produced nearly fifty tons. These facts should be borne in mind by the farmer, and while, on the one hand, they should warn him not to anticipate too large a return for the first year or two, they should, on the other hand, prevent him from being discouraged or disappointed, and so deterred from giving the application of sewage a fair trial.

(To be continued.)

* Paper read before a meeting of the Farmers' Club at Maidstone May 28.

THE number of Cornish pumping-engines reported for April is twenty-two. They have consumed 1,493 tons of coals, and lifted 114 million tons of water 10fms. high. The average duty of the whole is, therefore, 51,700,000lb. lifted 1ft. high, by the consumption of 112lb. of coal.

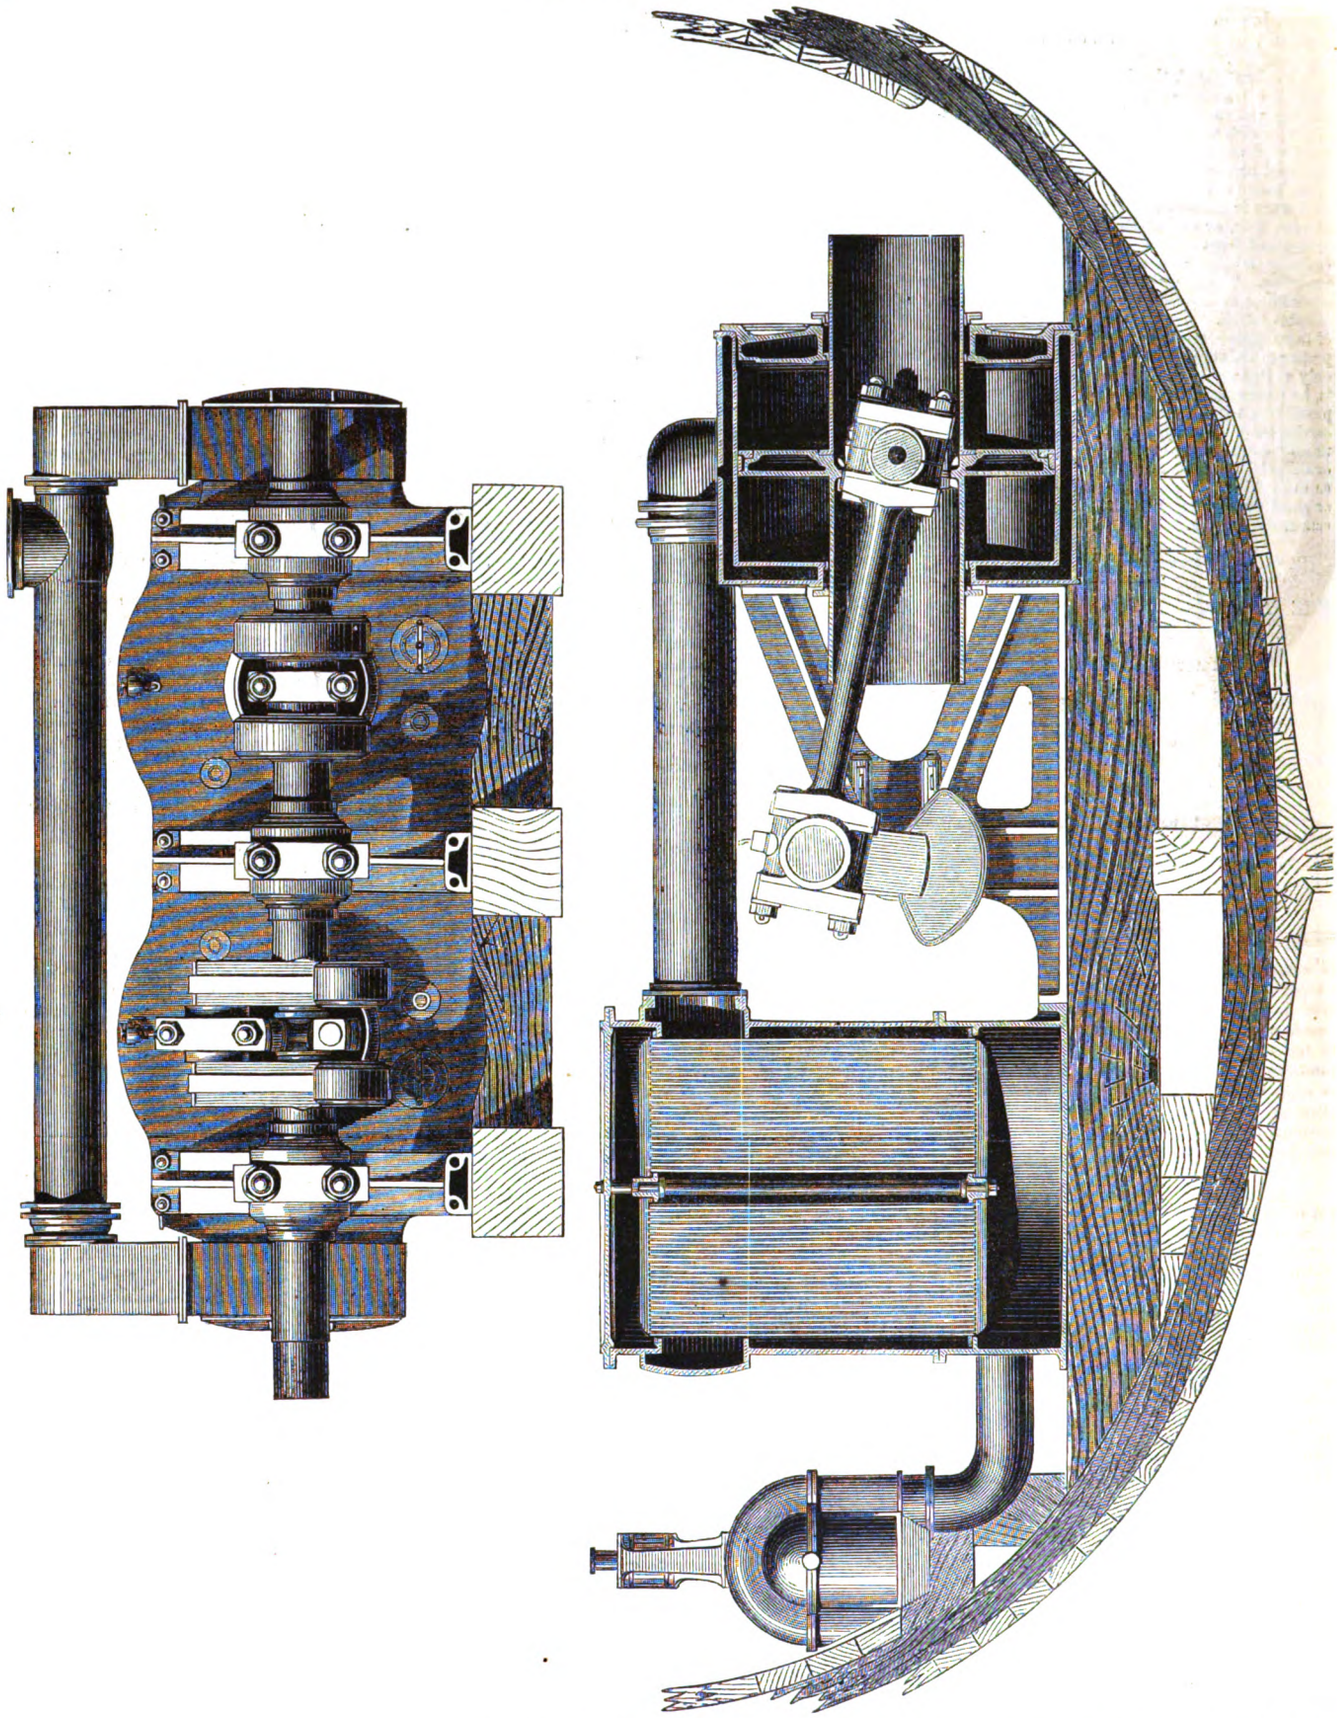
ENGINES OF H.M. SLOOP OF WAR "SAPPHO."

BY MESSRS. PENN AND SONS.



ENGINES OF H.M. SLOOP OF WAR "SAPPHO."

THE "Sappho," as our readers are aware, is a wooden unarmoured ship built from the designs of the Chief Constructor of the Navy. She is 212ft. long, 36ft. beam, and 1268 tons burden. The engines, which we illustrate above, are of 350-horse power nominal, and are intended to work up to about 2000-horse power indicated, when steam is cut off at one-third of the stroke. The principal dimensions are as follows:—Diameter of cylinder, 70in.; ditto of trunk, 30in.; effective area of piston, 3142·04sq. in.; length of stroke, 3ft.; diameter of air pumps, 17½in.; length of stroke, 3ft.—that of the main pistons; diameter of feed pumps, 4in.; number of tubes in surface condensers, 4776; diameter outside, 3¾in.; length, 6ft.; position vertical; shape of condenser, cylindrical; tube surface in condenser 5626sq. ft.; the tube joints are made with compressed wood ferrules. Heating surface, in boilers, 5718sq. ft. The "Sappho" has four boilers and sixteen furnaces. The grates 6ft. by 3ft., giving 288ft. of area. The boilers have in all 1120 tubes, 3in. diameter and 6ft. 6in. long. The boilers are fitted with superheaters, the tubes in which are 5in. diameter, 2ft. 3in. long, and 324 in number, giving a collective area of 954sq. ft. The screw will be 15ft. in diameter.

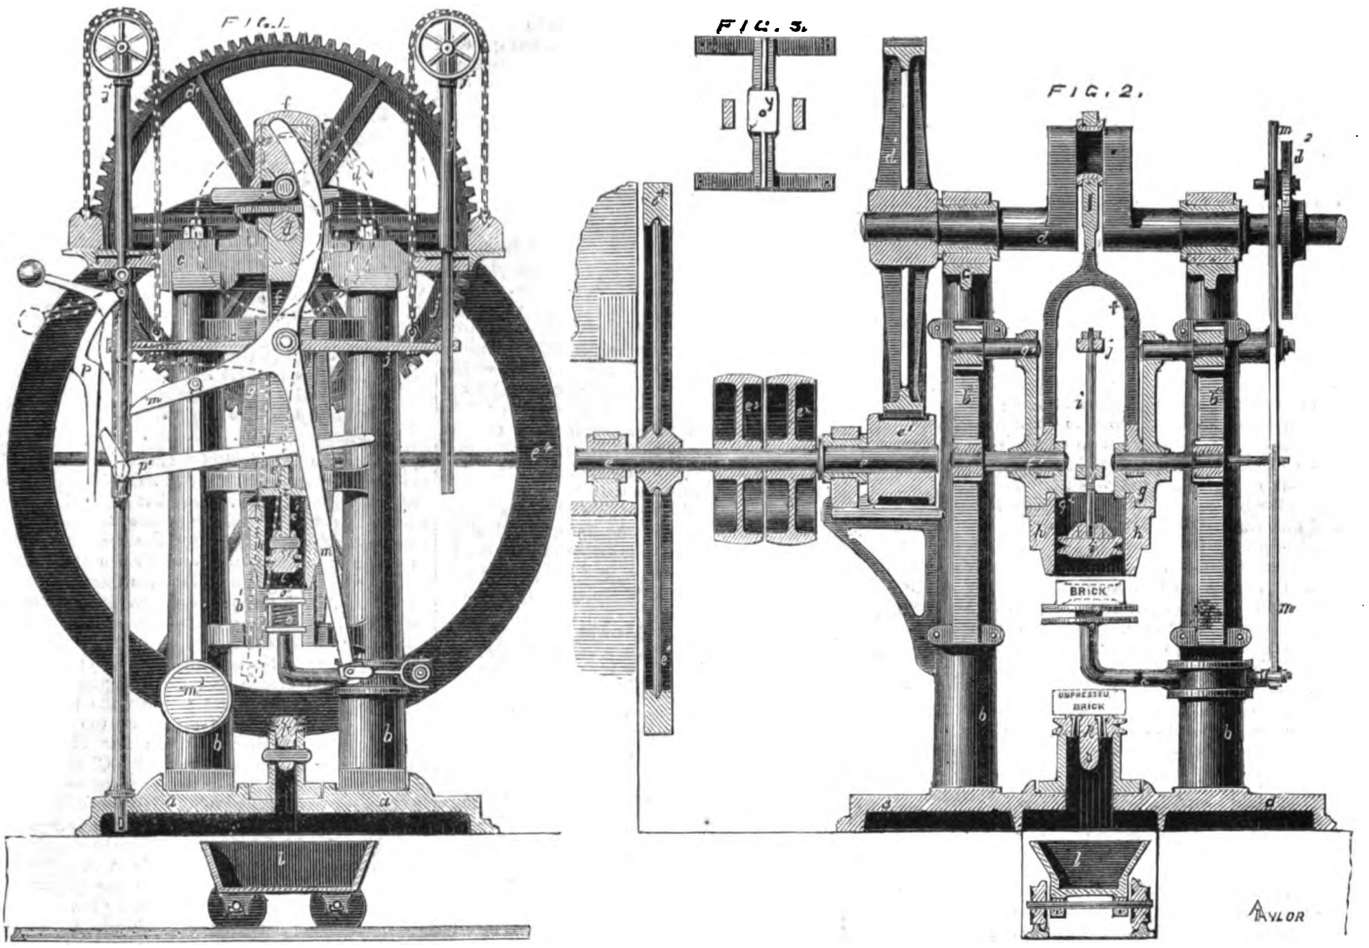
IMPROVED BRICKMOULDING MACHINE.

BY MR. S. JOHNSON.



The water is circulated through the condensers by a pair of centrifugal pumps, 22in. diameter, driven by separate engines. These pumps can be made to draw from the bilge when necessary. The cut-off is effected by Mr. Penn's well-known separate cut-off worked by a third eccentric. The main valves are worked by the usual link motion, the link being suspended by the middle. The proportions of these engines are excessively light, the whole weight being but 74 tons.

BRICKMOULDING MACHINE.

MR. S. JOHNSON, of Crook, near Darlington, has recently patented the brickmoulding machine shown in the accompanying engraving. It is a combined machine for the several purposes of moulding, perforating, and pressing bricks, and for removing them when pressed from the machine. In our engraving, fig. 1 is an elevation partly in section of this machine, fig. 2 being a sectional side view. It consists of a cast-iron bed-plate *a* on which are erected the four columns *b b* supporting a cast-iron framing *c* upon which are fixed the bearings of the crank shaft *d*. To one end of the crank shaft is keyed the spur wheel d^1 which is driven by the pinion e^1 fixed on the driving shaft *e*, which is provided with a fast and loose pulley e^2 and e^3 and with a fly-wheel e^4. The space between two of the arms of the spur wheel d^1 is provided with a weight to counterbalance the crank and moulding box. To the crank shaft *d* is jointed the upper end of the connecting rod *f*, the lower end of which is forked and jointed to the studs f^1, passing through the yoke or frame *g* to which the moulding box *h* is fixed. To the upper ends of the yoke *g* are fixed the studs g^1, and all the studs f^1 and g^1 are provided with blocks which work up and down in slides b^1 supported by the columns *b*.

Within the moulding box *h* is the top piston *i* which is moved up and down by the moulding box in the following manner:—To the piston *i* is fixed the piston rod i^1 fixed above to the crosshead *j* which is guided by the pillars j^1 fixed in the framing *c*; the upper ends of the pillars j^1 support the pulleys j^2, around which pass chains, one end of each of which is fixed to the crosshead *j*, and to the other end is fixed a weight to counterbalance the piston *i*. Immediately underneath the top piston *i* and moulding box *h* is the iron block or lower piston *k*, having one or more holes through it to allow the surplus clay or other substance to escape into the carriage *l* which runs on rails placed in a channel under the bedplate *a*.

The mechanism for removing the finished bricks consists of the following parts:—*m* is a three-armed lever mounted on a stud fixed to a bracket connecting two of the columns *b*; the curved upper arm of this lever is acted upon by a cranked pin projecting from the disc d^2 fixed on the crank shaft *d*, and the lower arm of the lever *m* is connected by means of a universal joint to the arm *n*, which swivels on one of columns *b*. To the arm *n* is fixed the pallet rest *o*, on which a loose pallet o^1 is placed; the finished brick is deposited on the pallet o^1. Between the pallet o^1 and the plate of the arm *n* is a spiral or other spring to allow the pallet to yield when the brick is delivered from the mould. To the horizontal arm of the lever *m* is suspended the weight m^1, the object of which is to bring the pallet o^1 back after the brick has been removed. This arm is held up by the catch *p* which is liberated when required by a prolongation of one of the studs f^1 acting on the lever p^1. The dotted lines in fig. 1 represent the position of the catch *p* and lever *m* when the pallet o^1 is held to one side.

The mode of operation is as follows:—The compressed brick is now supposed to have been deposited on the pallet rest *o* or on a loose pallet placed thereon, and the stud in the disc d^2 is going to act on the lever *m* to move the pallet and the brick on it to one side, while the pallet is moving to one side a piece of clay or other material of suitable stiffness and size, or a hand-made or impressed brick, is placed upon the block *k*, and the moulding box *h* and piston *i* are brought down upon it, the pressure being given by the crank *d*, and the final compression by the crank turning over its lower centre. The excess of clay escapes through the holes in the block *k* or through holes in the piston *i*, and the usual recesses in the upper and lower beds of the brick are produced by projections on the piston *i* and block *k*. Any device or ornament may be produced in the same manner, and if perforations are required in the bricks or other articles the perforators are attached to the piston or the block. When the compression is being given to the brick, the piston *i* is pressed down by the shoulders g^2 of the yoke *g*, and when the moulding box is rising the counterweights attached to the chains passing over the pulleys j^2 prevent the brick from at once being forced out of the moulding box by the weight of the piston *i*, but when the moulding box has risen to a height convenient for the brick being received on to the pallet, then the brick is thrust out by means of the piston *i* being prevented rising further by the crossbar *x* on the piston rod, which at a convenient height comes against the under side of the crossbridge *y*, shown detached in fig. 3, fixed to the columns *b b*, and forces the brick out of the moulding box while ascending, the moulding box being thus drawn away from the brick until the brick is fully delivered out.

As soon as the moulding box has arrived near the top the stud f^1 raises the long arm of the lever p^1, the short arm of which then forces back the catch *p* and liberates the arm of the lever *m*, which instantly drops and brings the pallet o^1 under the moulding box *h* to receive the brick, as shown in fig. 2. The moulding box *h* is made as deep as is practically convenient in order that the ends and sides of the brick may be smoothed and perfected after compression as it is being thrust out or as the moulding box is being drawn away from it. In some cases it is preferable to leave the compressed brick or other article on the lower piston block *k*, and to remove it by hand or otherwise. This may be accomplished by dispensing with the counterweights connected to the upper piston *i*, or by other means as practice may dictate, and according to the stiffness of the clay or other substance under operation. We may add that this machine is in use at the works of Messrs. Pease and Co., of Crook, where it is giving every satisfaction.

THE METRIC SYSTEM BILL.

AT a meeting of the Council of the British Branch of the International Decimal Association, Earl Fortesque, President, in the chair, the result of the recent discussions on the Weights and Measures (Metric System) Bill, brought in by Mr. Ewart, Mr. Bazley, Mr. Baines, Mr. J. B. Smith, and Mr. Graves, was reported as quite in accordance with former decisions of the House. The second reading of the Compulsory Bill was carried in 1863 by a majority of 110 to 75. majority, 35; the second reading of the Permissive Bill in 1864 was carried by 90 to 52, majority 38; and the second reading of the Compulsory Bill in 1864 was carried by 217 to 65, majority 152. Whereupon, on the motion of Sir J. Bowring, seconded by Mr. Yates, it was resolved as follows:—The Council have seen with great satisfaction the affirmation of the principle of the introduction of the metric system in this country by the passing of Mr. Ewart's bill by so large a majority of the House of Commons."

THE IMPROVEMENT OF THE PATENT OFFICE.

A DEPUTATION, composed of the following gentlemen, waited upon the Right Hon. B. Disraeli, on Thursday, the 21st ult., in reference to the carrying out of improvements at the Patent Office:—Mr. Dillwyn, M.P.; Mr. Laird, M.P.; Mr. Horsfall, M.P.; the Hon. A. F. Kinnaird, M.P.; Mr. Graves, M.P.; Mr. Gregory, President of the Institution of Civil Engineers; Sir C. Fox, member of the Institution of Civil Engineers; Mr. E. Woods, member of the Institution of Civil Engineers; Mr. Siemens, F.R.S., member of the Institution of Civil Engineers, and member of council of the Institution of Mechanical Engineers; Mr. Heywood, late M.P. for Manchester; Mr. Mallet, F.R.S., member of the Institution of Civil Engineers; Mr. E. A. Cowper, member of council Institution of Mechanical Engineers, and member of Institution of Civil Engineers; and Mr. C. E. Amos, member of Institutions of Mechanical and Civil Engineers.

Mr. Dillwyn, M.P., introduced the deputation, and observed that their object was to bring before the Government a knowledge of the great inconvenience and expense, both in time and money, necessarily incurred by those who wished to take out patents, and by the public in general, who wished to ascertain what was new and what was old in the history of invention. The loss of time and uncertainty arose in great measure from the want of proper subject-matter indices, containing very short abstracts, to act as keys to the subject of the patents, no complete examination of the specifications ever having been made for the purpose. It was, therefore, impossible to ascertain with any certainty whether an invention was new or old. It frequently happened that when it was of importance to know whether a given invention was new or old, as much as £50 or £60, or more, had to be expended in order to make a search at the Patent Office, as numbers of specifications were not under their proper headings. This and other defects at the Patent Office had been so strongly felt by engineers and others that they had taken the matter up on the part of the public, feeling that great injury was done, by the want of a full and perfect knowledge of numerous highly useful inventions and processes, described in the specifications, both foreign and English. They had, therefore, requested him to act in the matter, he having been chairman of a select committee of the House of Commons appointed to consider the arrangements of the Patent Office, some years ago. The deputation had already laid the case before Lord Romilly (the only permanent Commissioner of Patents), who admitted the justice of the claims, and after consultation with the Lord Chancellor (Lord Cairns), their lordships admitted that something was required to be done, and promptly, and signified their willingness to recommend the appointment of three additional Commissioners of Patents, to be chosen from practically scientific institutions, one gentleman to be a mechanical engineer, one a chemist, and one to represent science generally. These appointments would involve some expense, though the greatest expense would be incurred in securing proper and sufficient subject-matter indices of English and foreign inventions, printing catalogues of the excellent scientific and technical library and of foreign scientific books and periodicals, &c., collected with great labour by Mr. Bennet Woodcroft, the very painstaking clerk to the Commissioners. Lord Cairns and Lord Romilly had requested the deputation to wait upon him (the Right Hon. B. Disraeli), inasmuch as some expense would be incurred; it was considered that inventors had some claims, as they did not ask for anything out of the public purse, but simply for some portion of the gross sum of £120,000 a-year (now paid in fees and stamps), to be spent in perfecting the office. The expenses of the Patent Office were about £50,000 a year, leaving a balance of about £70,000 in favour of the Exchequer; and viewing the large annual expenditure for art and science, School of Mines, naval architecture, meteorology, South Kensington Museum, &c., it was thought that the persons who paid such a large annual sum into the Exchequer had some claims for the Patent Office to be made thoroughly useful to the public, and as the Lord Chancellor and Lord Romilly recommended the appointment of the three new practical Commissioners of Patents, the deputation trusted that the First Lord of the Treasury would sanction such expenditure as might be necessary to give the public the full benefit of the 60,000 inventions stored at the Patent Office. He begged to hand in a copy of the Act and various other documents relating to the subject. Other honourable members would have attended, but were engaged on committees at the House. He would call on Mr. Gregory to give any further information.

Mr. Gregory confirmed the statement already made, and would add that if anything it was rather against the interests of civil engineers to promote such improvements as had been named, but trusted Her Majesty's Government would be disposed to carry them out on public grounds. No doubt the theory was that the Patent Office should pay a certain amount to revenue and the expense of making inventions patent, or open to the public, so that a person could easily ascertain what was new and what was old, or had been published before in some way; this was not now done. There was an accumulation from the profits of the Patent Office of £340,000 over and above that intended as revenue, and there was an annual surplus of £54,000, exclusive of that called revenue. Now, the deputation humbly submitted that a sum of £30,000 might be appropriated out of the accumulation of £340,000 in order to properly examine, abstract, and index the 60,000 specifications which are in arrear, and that a further sum of £10,000 a-year might be appropriated for a proper staff in the Patent Office and to accomplish all that is necessary, still having the very large sum of £44,000 per annum beyond the profits called revenue.

Sir Charles Fox observed that he quite agreed with the last two speakers; the difficulties in the way of ascertaining whether an invention had or had not been patented were at present insurmountable without proper indices, and he thought it most important that such a state of things should be put an end to.

Mr. Horsfall, M.P., said that whatever difference of opinion there might be about the Patent Laws, all agreed in this, that the Patent Office ought to be carried on efficiently.

The Right Hon. B. Disraeli observed that the subject was one of the very greatest importance, and at one time he had taken considerable interest in it; he had hoped that the committee of the House of Commons would have brought about a solution of many difficulties connected with the whole system. Unfortunately, that had not been the case. It was a matter, no doubt, involved in many difficulties, but he thought there could be no doubt (and he had never had any doubt) of the expediency of good indices. Whenever a good system of indices was followed out, no doubt, as far as it went, it was a safe principle, and although persons might, even with good indices, lose a good deal of time, yet the chances were immensely in their favour. The representation of such a deputation as that before him, consisting of men of eminence and experience, would have due weight with the Government and they might rely upon the Government taking the matter into their consideration.

ON CERTAIN POINTS IN THE MANUFACTURE OF MALLEABLE IRON, WITH SPECIAL REFERENCE TO THE RICHARDSON PROCESS.

By Mr. St. John Vincent Day, C.E.

(Concluded from page 416).

I MAY call attention to one analysis of Scotch black-band ironstone, which we may safely take as a very fair mean representative of the productions of this country—it is from Gartsherrie, and my authority for it is a report made to the Prussian Government, by M. A. Erbeich. In the raw state it gives phosphoric acid (Po^5) 0·90, which corresponds to rather above 0·5 per cent. of phosphorus in the pig iron, but we may with safety take it at 0·5 per cent. for the sake of avoiding error in excess. Some samples of Scotch pig iron give sulphur and phosphorus in other proportions: for instance, some No. 3 grey coke iron from the Calder Ironworks contained sulphur 0·35 and phosphorus 0·39, and another specimen from Clyde contained sulphur 0·40 and phosphorus 1·30; the former of these is probably a fair mean representative of the quantities of sulphur and phosphorus combined in irons from the Scotch coal measures, whilst the latter is no doubt an extreme; taking, however, the mean of these three, we get—

Sulphur	0·375
Phosphorus	0·73

From the appended tables we have the values of British pig irons in regard to phosphorus represented in the following scale of ascending values of the quantity of that element by their mean of means:—

	Phosphorus per cent.
Hæmatites (various)	0·144
South Wales	0·473
Staffordshire (South)	0·48
Yorkshire	0·54
Scotland	0·73
Derbyshire	0·865
Staffordshire (North)	1·07
Northamptonshire	1·143
Cleveland	1·32

On the other hand, taking the mean of means of sulphur, we get the following order of ascending values in respect of the quantity of this element contained in the ores of different localities of Great Britain:—

	Sulphur per cent.
Cleveland	0·035
North Staffordshire	0·04
Derbyshire	0·0447
Yorkshire	0·052
Whitehaven (Ulverstone)	0·056
South Staffordshire	0·0614
South Wales	0·098
Northamptonshire	0·267
Scotland	0·283

Now, since the effect of combined sulphur is to prolong the time of melting, and phosphorus, on the other hand, diminishes that period, comparisons like those we have made are extremely useful in indicating the other chemical conditions in addition to those produced by the presence of carbon and silicon, that affect the duration of the period of melting of pig irons made in different localities. I am now of course speaking independently of the construction of the furnace, for this modifies the time of melting to a considerable extent, a high bridge and great depth of hearth tending to drive off and prevent the tips of the reverberated flame from attacking the charge so easily as in a furnace with a low bridge and shallow hearth. In the case of the Cleveland ore, we see at a glance that in the phosphorus series it is the very last, whilst singularly enough in the sulphur series it takes the first place; this theory shows it should be a very fast melting pig iron. In the case of North Staffordshire it is second in the sulphur series and seventh in the phosphorus series, the presence of sulphur being low and that of phosphorus very high, it should be a very fast melting iron. In the case of Derbyshire the phosphorus is much lower than in the preceding, and the sulphur but very slightly increased, it therefore should take a little longer in melting than the North Staffordshire pigs. In the case of Yorkshire the sulphur is increased and the phosphorus diminished, the time of melting should be longer still.

By making comparisons like the foregoing we obtain the period of melting of British pig irons in terms of the combined sulphur and phosphorus in the following order:—

Cleveland,
North Staffordshire,
Derbyshire,
Yorkshire,
Northamptonshire,
Whitehaven, Ulverstone (Hæmatite),
South Staffordshire,
South Wales,
Scotland.

Here we see the order is nearly the same as in the sulphur series, the exception being in the case of Northamptonshire pig, where the percentage of phosphorus is so very high that it predominates over the sulphur, and, therefore, materially shortens the period of melting. If these conclusions which I have deduced are compared with practical results they will, I believe, be found to very fairly coincide. In the case of Scottish irons these should take longer to melt than any others present in this country, and from the number of trials at different works that have been made on this point such deduction will, I believe, strictly correspond with the practical results.

We have now to consider the extent to which phosphorus and sulphur are removed in the ordinary process of puddling. On this point I have not had time to prepare tables, as in the case of pig iron, but it is my intention to do so on the earliest opportunity, as their value is evident enough to any one whose pursuits are directed towards improving the metallurgy of iron and steel. On the present occasion, then, I shall, to shorten the time I am occupying, merely bring forward analyses from the very best makes of malleable iron I have met with, some of these being taken from Dr. Percy's excellent work on "Iron

Digitized by Google

and Steel." An armour plate made at Lowmoor was found to contain 0·104 per cent. of sulphur, and 0·106 per cent. of phosphorus; now, as we have before seen, the mean values for Yorkshire pig iron are—

Sulphur	0·052
Phosphorus	0·549

in which case, either in the puddling or re-heating furnace, but most probably in the former, the sulphur is doubled, but the phosphorus diminished by the very great amount of ·433 per cent. This, however, being an armour plate, is a special case, and it is highly probable that a portion of better pig iron was mixed with the Yorkshire pigs ordinarily used at Lowmoor. The sulphur is considerably increased; it may possibly have been added from the fuel. In several other specimens of armour plates we find sulphur existing in the following percentages:—

Sulphur, 0·058, 0·121, 0·190, 0·118, ·058, 0·104.

And phosphorus in the following:—

Phosphorus, 0·030, 0·173, 0·020, 0·228, 0·089, 0·106.

In regard to the sulphur, it is higher in the examined plates than in all the different qualities of British pig iron except two, namely, Northamptonshire and Scotch, and since it is not in the least likely that either of these pigs were used in producing the plates, we may infer that sulphur has been added to the iron during its conversion and working into the malleable state, whilst the phosphorus is eliminated in every case to a very large extent, bringing its percentage considerably lower than in any known analysis of British pig iron. Comparing again malleable iron of South Staffordshire with the pig we have for the former:—

Sulphur	0·165
Phosphorus	0·140

Here also the sulphur is increased and the phosphorus diminished to a very considerable extent, and the same result obtains generally with any other comparisons that we may make. We are, therefore, led to infer that during the conversion of pig into malleable iron, sulphur is added to the iron from the fuel whilst the phosphorus is eliminated in a very large ratio. Of course, in considering the increase that takes place, we must bear in mind that the percentage in malleable iron is greater in proportion to the absolute amount of iron itself present than obtains in the pig iron, for the reason that in the latter case the carbon and silicon are present, whereas in the former they are nearly eliminated.

Comparing the foregoing results with analyses of iron made by the Richardson process, the superior eliminating power of that process is forcibly striking. In the analyzed samples of the iron made at the Glasgow Ironworks by that process, as I have before stated for the experiments, common Scotch pigs were used, and yet from that material we have obtained finished bar iron purer than anything that has ever heretofore been manufactured from British ores, and that, too, from pig irons which contain the highest percentage of sulphur, and rather above a medium of phosphorus; indeed, the removal of these two elements is so nearly complete, that, practically, they are not found. There can be no doubt remaining that the Richardson process has effected what has never before been done in Great Britain; by it we are enabled to produce a better and purer iron from the commonest pigs than we can yet depend on obtaining continuously by the common process of puddling from the best pigs. We can save a third of the time hitherto occupied in puddling, get a higher yield, save fuel, and, therefore, cheapen the production of malleable iron.

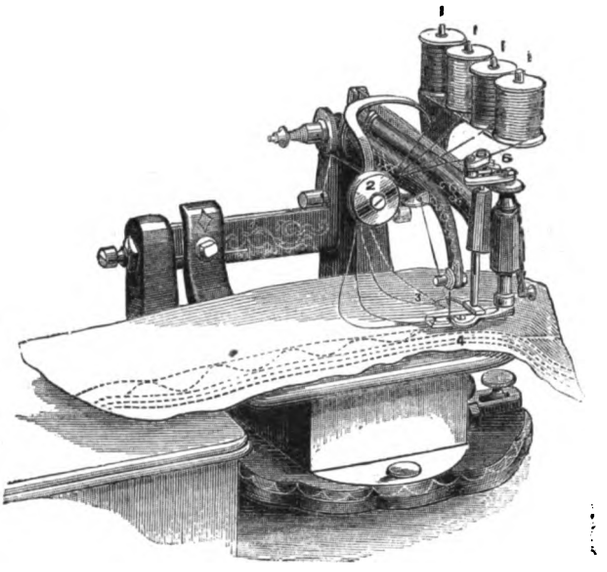
For the last two or three months there have been several furnaces making iron by this process at Parkhead; I have a large number of the returns as to the time of puddling a charge, besides a large number of results which I have noted myself from watching the conduct of the process on several occasions; these, however, I have not had sufficient time to tabulate, but I may state that the time from the moment of charging to taking out the balls varies from 1hr. 15min. to 1hr. 30min., whilst in another experiment that we made, having previously "fettled" the furnace very heavily all round, both the bridge, sides, and flue, the heat was out in 1hr. 20min.; this, without the fettling, would correspond to about 1hr. 10min., a remarkably short time, when we remember that at this forge, where very grey pig iron is principally used, the amount of time usually occupied for puddling by the old method is 1hr. 45min., and very often 2hr. The period of melting in the case of such pig iron is very high; I have on several occasions noted it, and find it to vary between 35min. and 50min.; this is doubtless due in a great measure to the high percentage of combined sulphur, and very probably to some extent depending upon the large proportion of silicon contained in it, as well as the hæmatite, a small portion of which enters into the mixture. Out of the hundreds of bars that have now been made in this manner at Parkhead, from the "common mixtures," too, it is particularly important to remark that not a single bad bar has been met with. The iron works better under the shingling hammer as well as the rolls. In the puddled bars after they have passed through the mill and are cooled, their appearance externally is frequently as smooth and even as good finished merchant bars, whilst the fracture shows the perfect regularity of the metal. With puddled bars of the same mixtures made in the ordinary manner, when cold and worked to the same extent they are much more full of flaws and fissures, gaping wide open at the surface, and the fractures always show much want of uniformity, while the microscope usually reveals the presence of a great deal of graphitic carbon. Puddled bars from the common mixtures will not usually bend through a greater angle than 40deg., without cracking right across; some of them break off quite cold-short before having reached that angle, whilst the best bars of such mixtures rarely if ever bend 45deg., and usually break in half before reaching that extent of flexure; but with bars made by the "Richardson process," out of precisely the same materials, I have seen them, I may with certainty say, on most occasions bend completely round to 90deg. without breaking, frequently without showing a surface crack, and some specimens that have been tried were doubled up without effecting a complete fracture. Altogether, the advantages of working by this process are so great as to require no further comment from me.

Since writing the foregoing it has occurred to me that I should mention the now well-ascertained fact that in the puddling furnace some of the phosphorus passes from the charge into the cinder, but by no means the whole of it. This circumstance led Dr. Percy to propound his theory that still more of that element existing in the charge as phosphide of iron, was liquated or sweated out after the metal was balled. If there be any truth in this supposition, it appears to be confirmed by the results of the mode of working to which I have now called your attention. The balling process is of longer duration, as I have already explained; therefore, greater time is afforded for this supposed liquation of the phosphide. I merely throw this out as a hint; it is rather soon yet to attempt to form a conclusive theory. That phosphorus is not got rid of by oxidation in combination with iron is certain, or it would unquestionably be eliminated in the Bessemer converter, every means hitherto tried having utterly failed to remove it.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending May 30, was 2,268; total number since the opening of the museum, free daily (May 12, 1858), 1,302,811.

THE BELGRAVIA SEWING MACHINE.

BY MR. J. MABSON.



THE ADJUSTABLE BELGRAVIA SEWING MACHINE.

AS promised last week, we now proceed to give further particulars of the sewing machine exhibited at the conversazione of the Institution of Civil Engineers, by Mr. Mabson, of 20, High Holborn. This apparatus has been made very perfect by Mr. Mabson, who has very properly named it the "Adjustable," inasmuch as it can be adjusted to make any known stitch. It makes the Wheeler and Wilson lock-stitch, the Wilcox and Gibbs stitch, the Grover and Baker stitch, the pearl stitch, the cable stitch, and, finally, the embroidery stitch on the right or upper side of the cloth. The arrangement by which this latter stitch is made forms the subject of the annexed engraving. It is the embroiderer, and consists of a simple apparatus made to open and close in a similar manner to a pair of callipers. The fixed arm of the machine has a bracketed plate for carrying the required number of reels of cord 1 1, of various colours. The cords are led over a roller 2, down through eyes on the ends 3 4 of the calliper-like apparatus. This apparatus opens by means of a vertical rod actuated by the working parts of the machine, and is closed by an india-rubber band. The forks of the apparatus, which are curved, are made to cross every alternate movement, by which means the embroidery cords are made to cross and recross each other, each crossing being secured by the needle thread. By the arrangement of the colours and thicknesses of the cords, every variety of pattern and design may be worked. This is perhaps the most important of Mr. Mabson's improvements, and renders the sewing machine a complete apparatus. It performs the work on the upper surface of the material, and in sight of the operator, thus overcoming a hitherto insuperable difficulty.

SURVEYS OF JERUSALEM AND SINAI.

COLONEL SIR HENRY JAMES, Director-General of the Ordnance Survey, reports that the expense incurred by publishing the survey of Jerusalem will soon be more than covered by the profits arising from the sale of copies. The demand, especially for the photographs, has been so great that it has been difficult to meet it during the winter months, when very few photographs can be taken. The survey of Jerusalem having given so much satisfaction to the public, the Rev. Pierce Butler, of Ulcombe Rectory, Kent, proposed that a survey of Mount Sinai and of a considerable portion, if not the whole peninsula, of Sinai should be made under the direction of Sir H. James, with a view to identify the route taken by the Israelites, and the places mentioned in the Bible. Mr. Butler had obtained the sanction of the Secretary of State for War to the undertaking, and had issued circulars which brought subscriptions from several noblemen and gentlemen desirous of seeing this survey made, and he had paid for his passage to Alexandria, with the intention of proceeding to Cairo and Suez for the purpose of making prelimi-

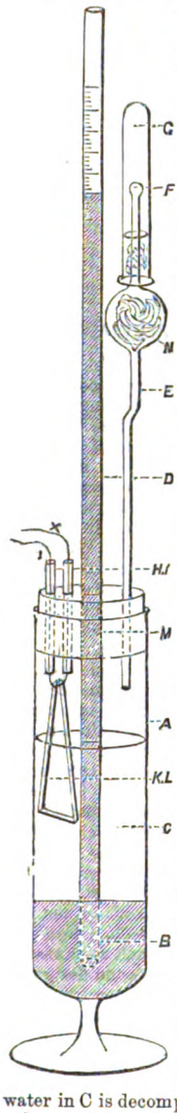
Digitized by Google

nary arrangements for the expedition, when he was suddenly taken ill and died in February, on the very day he was to have left England. He was a man well qualified for the task he was about to undertake.

A NEW FORM OF VOLTAMETER AND VOLTASTAT.

BY DR. F. GUTHRIE, F.R.S.E.

THE apparatus illustrated in the accompanying engraving was exhibited by Dr. Guthrie, at the recent conversazione of the Institution of Civil Engineers. This instrument may be advantageously used when a galvanic current of great constancy is required for a considerable time. When interposed in a circuit it allows a certain quantity of the current to pass, and it measures the amount which passes. Its construction and use are the following:



—A is a wide test-tube on a foot. B is mercury. C is dilute sulphuric acid. D is a long tube, open at both ends, passing through the cork M, and dipping under the mercury. E is a tube passing through the cork, and open below; it carries a bulb N, containing fragments of linen. The upper end is closed, with the exception of a microscopic opening F. H and I are the electrode wires, protected by glass tubes where they pass through the cork. K and L are platinum electrodes, in the shape of narrow strips of foil converging towards the top, and kept apart at top and bottom by strips of glass fused on to the platinum. G is a little test-tube, which serves to protect the end of the tube E from dust. It is separated from E by fragments of linen.

The only point requiring particular attention is the formation of the capillary opening F. This opening is best made by blowing a little bulb at the end of the tube, bursting a little hole in this before the blowpipe, and allowing the whole to collapse while the air is continually injected. Several such tubes should be prepared. It is not difficult in this way to get an opening in D so extremely small as not to allow the mercury, when at the top of D, to fall in less than ten minutes or a quarter of an hour. The cork and top of the tube C are made perfectly air-tight by sealing-wax. On connecting H and I with the poles of a battery, the water in C is decomposed; the detonating gas can only escape by the opening F. The hindrance it meets with on account of the small size of F causes it to force the mercury up D. The effect of the rise of the mercury in D is twofold; it forces more gas through F, at the same time that it lays bare a part of the electrodes, leaving the active portions of them further apart. The quantity of gas produced is accordingly diminished. In other words, an increase in the strength of the current produces effects which diminish the strength of the current. The instrument is a regulator, which may be compared with the governor of a steam engine.

It is found that the mercury rises to a certain height in D, and remains nearly at that height for many hours. Since a certain height of the mercury in D corresponds to a certain pressure in the interior, and since the latter corresponds to a certain rate of delivery through F, it follows that the quantity of electricity passing through the instrument is directly measured by the height of the mercury. The actual relation between the height of the mercury and the electricity which passes may, of course, be measured either by interposing a galvanometer or actually measuring the quantity of gas evolved by fitting a gas-delivery tube over F, &c. Nevertheless, an exceeding gradual depression in D must occur even with a perfectly constant current, on account of the removal of a portion of the liquid C by electrolysis. For many purposes this is negligible, namely, when the instrument is used as voltastat. It is clear that, as a certain height in D corresponds to a certain activity, the amount of water lost from C in a given time is measured by the height in D. Hence, on knowing the relative diameters of D and A, and knowing the amount of water decomposed in a given time, a simple calculation serves to make the minute correction.

FRENCH IMPORTS.

DURING the first two months of the present year there were imported from the United Kingdom to France 2,775,925 kilogrammes of coal, 4,873 of coke, 10,220,817 of coal tar, 1,232,834 of coffee, and 33,000 of wheat. Cotton was imported from this country amounting in value to 17,494,768f., cutlery to 27,373f., fine stoneware to 66,884f., and fine porcelain to 26,744f. Steam engines, fixed and marine, to 900f., agricultural machines to 625,727f., and machine tools, &c., to 191,718f. There were also imported 28,668 kilogrammes of tools of pure steel, 3,247,618 of pig iron, and 25,141 of iron bars of all kinds; 8,239,621 kilogrammes of iron ore being imported from Belgium, and 12,421,632 from Algeria. Of cast-iron, 53,541 kilogrammes were sent from the United Kingdom, and 106,736 from Belgium. The total imports of copper were 1,247,021 kilogrammes; of lead, 980,568; of tin wares, 5,870; and of zinc, first fusion, 4,188,640 kilogrammes; all these metals being imported from the United Kingdom, Holland, Belgium, and Spain. Of raw silk 415,400 kilogrammes were imported, of thrown silk 154,600, of waste silk 376,500, and of silk thread 69,900 kilogrammes, most of these articles being sent from the United Kingdom. Of textile manufactures, there were imported from the United Kingdom 102,622 kilogrammes of calicoes, cambrics, and muslins, bleached and unbleached; 37,043 of cords, moleskins, &c.; plain net to the value of 174,647f.; plain unbleached linen, 24,592 kilogrammes; carpets amounting in value to 104,794f., cloths to 1,127,461f., mixed stuffs to 5,532,729f., alpaca, vigona, &c., to 332,569f., and tissues of cashmere manufactured by hand in countries out of Europe to 608,446f.

Legal Intelligence.

VICE-CHANCELLOR'S COURT.

June 2.

(Before Vice-Chancellor GIFFARD.)

THE ATTORNEY GENERAL *v.* LEONARD EDMUNDS.

JUDGMENT.

THE arguing of this case was resumed on Tuesday last, by Mr. Digby Seymour, Q.C., and Mr. J. N. Higgins, on behalf of Mr. Edmunds, and the Attorney-General on the part of the Crown. The case has been reported at such length in all the daily papers, that we need do no more than append the substance of the Vice-Chancellor's judgment. His Honour observed that he was happy to say the arguments and the evidence adduced on behalf of Mr. Edmunds had been successful in clearing his character from all imputation. They had satisfied him that the defendant's liability, whatever it might be, was a liability arising from mistake, and mistake under circumstances of very considerable difficulty, brought about in some respects because he could not obtain the audits which he asked for (his Honour thought) in 1834, and subsequently in 1852 or 1853, and brought about also by what was a most unfortunate Act of Parliament, which was passed with reference to a given state of circumstances, when, in point of fact, those circumstances changed very materially afterwards. Having made that preface, his Honour said he might add that it was not without regret that he had come to the conclusion that in other respects the arguments which had been adduced on behalf of the defendant were not successful. He did not doubt that the Court had jurisdiction in a case of this nature to decree accounts, and he must hold that the Crown was entitled to a decree for account. After reading the provisions of the Act of Parliament, which fixed the salaries of various offices, including that of clerk of patents, and provided that the salaries should be taken "in full satisfaction for the duties of the said offices, and of all expenses incident to the performance thereof," and that all fees and emoluments received in the said offices should be accounted for and paid, his Honour said that he much regretted that the words of the Act left him no alternative but to decide that the deductions claimed to be allowed by Mr. Edmunds could not be made. It appeared to him to be a case of great hardship on the defendant, but this was the letter of the Act. The salary was to cover all expenses. He must, therefore, decree the accounts sought by the information, viz., accounts of the fees and moneys received by the defendant in his said offices, but directing that all just allowances should be made, and all settled accounts be left undisturbed. Further, he must declare that the defendant must account for all profits made by moneys originating from, or emanating, originally or otherwise, from moneys drawn from the Patent Office, and declare that the defendant was not entitled to make the deduction of 12s. 10d. for parchment and engrossing. His Honour said it was with regret he found himself compelled by the terms of the Act of Parliament to make that last declaration. He repeated, as he had said at the outset, that he thought the defendant's evidence had removed any imputation that could be justly or fairly cast upon his character; and, having regard to all the circumstances, the very difficult position in which he was placed, and the fact of an audit being refused, he should certainly not make Mr. Edmunds pay any costs of the hearing of this cause.

Correspondence.

THE PRESENT CONDITION AND FUTURE PROSPECTS OF MACHINE MANUFACTURE IN RUSSIA.

TO THE EDITOR OF THE "MECHANICS' AAMGZNE."

SIR,—I beg to thank you for inserting my first letter on the above subject in your impression of April 9. In resuming the question, permit me first to correct a small typographical error, which, I fear, has been caused by my indistinctly forming some letters. The town from which I write is "Kharkoff," sometimes spelt Charkoff, and the railways to which I referred are the Koursk-Kharkoff and the Kharkoff-Taganrog.

In attempting to lay before your readers more fully some proofs of the feasibility of my scheme, it will be necessary to direct attention to two things—first, the work to be done; and, second, the place, that is, the part of the country most suitable for carrying on that work. Before beginning, however, to discuss either of those points, I wish to make a few remarks upon another subject so intimately connected with the main proposition that the same line of argument may serve in illustration of either or both of them. There may be some who think that it is not quite patriotic in me to propose a scheme whereby British capitalists and engineers would be required to emigrate to a foreign country for the purpose of carrying on manufactures. But there can be few who will be disposed to find fault with me, if I can point out some means of increasing the demand for English manufactures here. What I have to say on that point is this, that there is no branch of English manufacturing industry so badly represented in the south of Russia as that of machine making. I do not mean in quality of workmanship, but in what, for a commercial country like England, might be thought much easier to attain perfection in Plainly and simply, then, I think I may safely assert that in the whole south of Russia, between Moscow and Odessa on the one hand, and between Warsaw and Astrachan on the other, there is not one practical engineer engaged in the sale of English machinery, and few of any sort accredited direct from English firms as agents.

If these lines should happen to meet the eye of a gentleman connected with one of the—in this part of the world—best known English engineering firms, he will fully bear me out in my assertion. He travelled through the greater part of Russia, some years ago, purposely to gain information on this point, and will, most likely, recollect the conclusion he arrived at, and the strong expressions he used in a conversation with me on the subject in this town. The German manufacturers are not so careless in this respect, and the result is that they carry off many good orders which customers would willingly give to English houses. English machinery, so far as it is known here, bears a very good name, and users would, under most circumstances, willingly employ it. But in a country like this a customer requires something more than the mere act of selling him a machine. He requires advice in preparing for its reception and fixing, and in most cases assistance in adopting it to his purpose, as there are few here who enter into any line of business requiring machinery who have had any special education or practice in the adaptation of machinery to it. I could give

Digitized by Google

many instances of the difficulty of getting at English machinery, but let two suffice; and these two will bear upon an important branch of my subject, namely, the supply of machinery for sugar making and refining, and which I intend to speak more fully when I come to discuss the place suitable for a centre of operation. One gentleman, the owner of two and part owner of three other raw sugar manufactories, wishes this year to build a refinery, and as he has at work a small English-made steam engine, with which he is very well satisfied, he expressed the wish to me to have all machinery for the new refinery from England. As there is no agency here for the sale of such machinery, I proposed to accompany him to England to purchase or order the machinery. He would have consented, but as his time is much occupied and he never was out of the country before, while at the same time some parties having suitable machinery on sale from German houses got scent of the order, he was induced to conclude a bargain with them.

The other instance is that of a landowner, who wishes to build a raw sugar factory, and having travelled in former days in England, he was not afraid of going again to purchase machinery. But here came another difficulty in the way; he, although known here for a safe man, could not expect to get credit from strangers, and he has not the ready cash to pay for all the machinery at once; so the affair ended in a Warsaw house taking the order, agreeing to furnish plans and superintend the erection of the buildings, then to fix the machinery, and after working it the first year receive the remainder of the contract sum out of the first proceeds, and at last give up the keys of a complete manufactory. The most vexing part of the whole affair is this: that both these gentlemen were firmly convinced that English engineers could make and erect steam engines, hydraulic presses, vacuum pans, &c., quite as well as German, French, or Polish makers; the great difference is that these are here almost on the spot, while those are difficult to get at with orders.

These considerations induce me to lay another proposition before you, a proposition also like my former one, not got up on the spur of the moment, but, as well as it, long thought of, and only kept in abeyance until the time should come for bringing it to light. The users and would-be users of machinery say the hour is come, now we only want the men. I would, therefore, propose, secondly, that a number of English engineering firms, having different specialities, should lay their heads together and establish an agency and depôt of machinery here, with practical men to conduct it in all its branches. By practical men I mean not mere salesmen, but men who are practical engineers, and who could, whenever required, undertake the erecting of the machinery they sell. It might be thought that the language would cause a difficulty, but anyone speaking German or French will get on just as well with customers as if he spoke Russian; whilst a man who wishes to learn can, in the course of eighteen months, or, at the most, two years, pick up enough Russian to enable him to give directions to workmen. In making this second proposition I have by no means lost sight of my first—on the contrary, they can work together; and I consider that an agency of this sort would form a very good basis for the operations of the proposed factory, the more so as I think I can prove that the place most adapted for the one, is also the very part of the country most suitable for the other.

I had got so far with my letter, and meant to have gone on to speak of the work to be done, but by a strange coincidence I have just received the last number of the Transactions of the Russian Technical Society, containing, from native sources, a confirmation of my views on the subject, chiefly treated of in this letter. This society, yet in its youth, unlike English societies of a similar nature, is composed of both civil, military, and mechanical engineers, together with architects, chemists, &c., only holding their meetings in separate sections, but in reality forming one body. Its members, ever since its formation, have devoted a good deal of time to inquiring into the difficulties met with by makers and users of machinery in Russia, with a view to assist in their removal. The Riga branch of this society, among a series of resolutions connected with the proposed protective duty on machinery, passed the following one, with a translation of which I cannot do better than close my present letter.

Fourth resolution:—"That it is advisable to co-operate for the organization of associations, having for their aim the furnishing of machinery, especially that for manufactures connected with agriculture, in which the purchase of machines, whether in this country or from abroad, shall be under the superintendence of efficient mechanical engineers, paid by the society." The reasons given for this are:—"That under the present system of acquiring machinery, the purchaser, more especially if he is a landowner, seldom appears to either the home or the foreign machine manufacturer personally or as a regular customer. By such casual purchases he has less chance of being suited by the seller than if he acquired the machinery from a large society or company, the operations of which would be more extended than that of single manufacturers acting separately. A purchaser unacquainted with machine making often deceives himself, both in the choice of a machine and in that of the maker. An association, on the contrary, with a well-informed and well-paid engineer in its midst, presents a guarantee not only to the purchaser for the quality and adaptability of the supplied machinery, but also contributes to the success of the honest manufacturer, securing him a regular sale for his goods. By means of such an association, machine makers would be better able to adapt their machines to special operations. It would also cause those manufacturers, whose machines may be by some cause or another found unfit for the work required, either to improve them or lose orders."

If the passing of such a resolution as this is found to be called for in the neighbourhood of Riga, and is echoed by practical men in St. Petersburg, what must be the condition of affairs in the interior? Simply this: that the purchaser is at the mercy of the seller, who, being himself ignorant of the practical working of the machines he sells, has for his object to get rid of his customer as easily as he can, providing he can induce him to buy something. In the case of the machine not being suitable for the wants of the customer, the name of the manufacturer generally suffers, and the demand for his machine decreases. With your permission, I will in my next endeavour to give some idea of the work to be done, and the place suitable for doing it—a branch of the subject from which I have been led away for the present, owing to my anxiety to confirm my opinions by quoting those of others.—I am, Sir, yours, &c.,

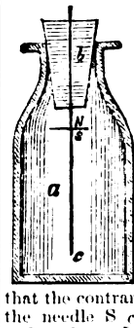
ALEXANDER CAMERON, Mem. R.T.S.

Kharkoff, May 6.

[Our manufacturing engineers ought to feel themselves indebted to Mr. Cameron for pointing out for them a course of action in these dull inactive times. We thank our correspondent, and look forward to the continuation of the subject.—ED. M.M.]

MAGNETIC PHENOMENA.

SIR,—Herewith I send you a rough sketch of the vertical section of an instrument I used in making experiments on magnetism. *a* is a common glass bottle, *b* a cork; through the cork is passed a common needle, the point downwards. This point is magnetized by the north pole of a common horse-shoe magnet. Another needle, of which the point is magnetized by the south pole of the magnet, is hung to it. Now, I should like to know the explanation of two different phenomena observed by me—first, in presenting the north pole of the magnet to the hanging needle at *c*, I found that the needle was attracted, while the contrary took place on presenting the south pole. I would suppose that the contrary ought to have taken place. Second, the needle S *c* is in continual irregular oscillation, and, as far as I can observe, the direction is from east to west, the eyepiece at *c* describing an ellipse. I hope you will find this curious enough to give it a line in your valuable paper, especially as the experiment is easy to be made. To observe the irregular oscillations of the needle, I put the bottle on the chimney-piece, being of marble, after having cleared it of everything that could attract in any way.—I am, Sir, yours, &c.,



A DE B.

Delft, May 31.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Meetings for the Week.

TUES.—Royal Institution.—Dr. M. Foster on "The Development of Animals," at 3 p.m.

THURS. — Royal Institution.—Sir J. Lubbock on "Savages," at 3 p.m.

FRI.—Royal Institution.—Professor Frankland on "The Source of Light in Luminous Flames," at 8 p.m.

SAT.—Royal Institution.—Sir J. Lubbock on "Savages," at 3 p.m.

Naval, Military, and Gunnery Items.

THE transformation of the artillery in Spain is now terminated, the army of that country now possessing 130 steel breech-loading guns.

THE annual general meeting of the National Artillery Association will be held on Monday, June 8, at two o'clock p.m., at the new rooms of the National Artillery Association, No. 12, Charing-cross.

THE Prince of Wales has consented to dine with the corporation of the Trinity House on Trinity Monday next. Prior to the banquet there will be Divine service in the church of St. Olave, Hart-street, at which the brethren will attend.

THE floating shears in Chatham Dockyard, lent by the Admiralty to Messrs. Maudslay and Co., having been employed in masting and raising the heavy machinery on board the Prussian ironclad frigate "Konig Wilhelm," in the Victoria Docks, have been towed back to Chatham, for the purpose of lifting the large iron masts into the armourclad turret ship "Monarch," 6, 5,100 tons, fitting for commission.

A RECENT Gazette contains a notice informing the officers, seamen, marines, and others interested, that the distribution of the tonnage bounty, &c., arising from the capture of a slave dhow, name unknown, by Her Majesty's ship "Highflyer," on the July 28, 1866, will commence on Wednesday, the 10th proximo. Shares: Captain, £41 15s. 2d.; second class, £7 14s. 3d.; third, £6 3s. 4d.; fourth, £3 19s. 5d.; fifth, £2 4s. 2d.; sixth, £1 19s. 9d.; seventh, £1 6s. 7d.; eighth, 13s. 2d.; ninth, 8s. 9d.

MUCH inconvenience having been occasioned by the employment of regimental officers for an undue period on the personal staff of general officers, and of governors of the colonies, it has been decided to restrict the term of service in such capacity to five years in the former and six years in the latter case. When an officer has completed such period, he will be required to rejoin his regiment, and to do duty with it two years before he can be again similarly employed, unless he is willing to exchange to temporary half-pay.

AN order has been received at the Royal Engineer establishment, Chatham, directing volunteering from the companies of Royal Engineers at head-quarters for men to be employed with the corps now being formed to be attached to the Department of Public Works in India. The non-commissioned officers and Sappers who have already volunteered are undergoing a special course of instruction in military engineering, levelling, surveying, and road-making, at the Royal Engineer establishment, to prepare them for employment on the public works in India.

THE wretched, but happily abortive, attempt upon the life of the Duke of Edinburgh has met with universal denunciation, whilst his escape and recovery are the subject of general congratulation. They form the theme of a spirited song, "God Bless Our Sailor Prince," by Mr. J. E. Carpenter, which has been set to music by Mr. Stephen Glover. Messrs. Cocks, the publishers of this song, have sent us a copy of the words, which will form an interesting addition to our national songs.

Miscellanea.

THE pearl fishery grounds recently discovered at Western Australia extend along the coast for 1,000 miles. Upwards of sixty tons of pearl oysters were fished up in December last, and sold for £100 per ton.

IN the recent presentation of the various prizes of the Academy of Sciences, a touching incident

occurred: M. Bour received a gold medal in honour of the analytical labours of his son, who was snatched from science at an early age.

BY the death of the late Dr. J. Davy, the service of plate presented to Sir Humphry Davy, in 1817, by several coal mine proprietors, for the discovery of his celebrated safety-lamp, reverts to the Royal Society. The value of the plate is £2,500,

THE Allentown rolling mill is one of the largest establishments of the kind in Pennsylvania. It is for the production of railroad iron exclusively, and turns out 400 tons of rails per week. The daily work is 260 rails, 30ft. long, and weighing 561b. to the yard, or 5601b. each.

PAPERS by Clements R. Markham, Esq., on "The Topography of Abyssinia," and by Dr. G. Neumayer on "The Scientific Exploration of Central Australia," will be read on Monday next, at the meeting of the Royal Geographical Society. Sir R. Murchison will take the chair.

NEAR Cologne, in the circle of Sieg, a tremendous hailstorm, accompanied by a waterspout, a few days back, devastated the territories of about twenty villages. The wind, which was extremely violent, tore up oaks of more than 100 years old, and blew down several dwelling-houses.

IT has been calculated by Professor Breithaupt that during the 640 years the Freiberg mines had been worked, dating down to 1825, the mines of Freiberg produced not less than 82,000 cwt. of silver, and that the amount yielded in 1850 alone was not less than 800,000 thalers.

A SHARP shock of earthquake was experienced in Guatamala on April 8. The shocks were repeated for days in succession, but no damage was done to the buildings. The imports and exports of the three ports of Salvador have been much greater than any previous year.

THE visitors to the South Kensington Museum during the week ending May 30, 1868, were on Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 7,787; on Wednesday, Thursday, and Friday (admission, 6d.), from 10 a.m. till 6 p.m., 1,778. National Portrait Exhibition, by payment, 2,423; total, 11,988. Average of corresponding week in former years, 12,765. Total from the opening of the museum, 7,409,957.

AT the general monthly meeting of the Royal Institution of Great Britain, held on Monday last, W. Pole, Esq., F.R.S., in the chair, Mr. Alfred Morrison and Rev. J. George Wrench were elected members of the Royal Institution. The special thanks of the members were returned to Sir Henry Holland, Bart., the President, for his tenth annual donation of £40 to the fund for the promotion of experimental researches.

IN France the greatest distance over which a telegraphic message can be transmitted is about 600 miles; in Prussia, about 500; in Belgium, about 160; and in Switzerland, about 200 miles. The charge for a message of 20 words over the greatest distance in France is 1s. 8d.; in Prussia, 1s. 6d.; in Belgium, 5d.; and in Switzerland, 5d. In Great Britian 2s. is charged for the transmission of a messuage over 500 or 600 miles, and 1s. 6d. for any message sent 160 or 200 miles.

UNDER the superintendence of Mr. Lee, architec to the Earl of Dudley, the rebuilding of Her Ma-t jesty's Theatre has just been commenced, Messrs. Trollope and Sons being the contractors. By the terms of their contract the building is to be finished in forty weeks from the present time, under a penalty of £1,000 for every week beyond that time. It is intended that the accommodation shall be much increased in the new building, the last one holding not more than 1,700 persons.

IT is said that measures are being taken for the holding of industrial, artistic, and agricultural exhibitions at Lyons next year, to open in May, and close in August. The three exhibitions will be separate from each other; the first to be held on the new Cours Napoleon, the second in the Museum or Palais des Arts, and the third in the park of the Fete d'Or. A great festival of the orpheonists and of the musicians of the Rhone and the neighbouring departments is proposed to be held at the same time.

WE had occasion last week to rebuke the "Daily Telegraph" for having stolen some of our thunder, in the matter of silver coinage; it has now pilfered some of our lightning anent electricity. It has had the coolness to abstract from our "Notes" of last week the item on the application of electro-magnetism to ladies' ornaments, and, with a word altered here and there, to parade it as its own in leader type. But this is the old practice of the "Gaily Bellowgraph" (as the "Standard" dubs it), and we are sorry to see it so confirmed in its sinful ways.

A CENSUS of Queensland was taken on March 2. The returns are not yet fully made up, but the population is over 100,000; it was only 30,000 on April 7, 1861. The population of Brisbane, the municipality, is stated to be 15,032; Ipswich, 5,026; Rockhampton about 200 more; Maryborough not quite 3,000. The population of the province of Otago, New Zealand, is returned as 48,480, according to the census of 1867—29.819 males, 18,661 females; 12,405 at the goldfields, 36,075 in the rest of the province. The population of Dunedin city and harbour is returned as 12,776.

THE congregation of the ancient church of Wharram Percy, Yorkshire, have been somewhat surprised to find a breed of foxes in possession. An air drain for ventilation from the outside has been used as an "earth," and by this means access has been gained to the pulpit, beneath which an old fox and her litter of fine cubs are, except when unearthed during Divine service, comfortably domiciled. The novelty has been communicated to Morgan, Lord Middleton's huntsman, who declares that during his forty years' experience he never before heard of such a circumstance, and never met with a finer brood of foxes.

THE inspectors of factories, in their report just published, point to the fact that the extension of the factory system is the nearest approach to a compulsory system of education, and believe that the Factory Acts Extension Act, 1867, and the Workshops Regulation Act, 1867, will eventually be accepted as a national code. The number of accidents from machinery reported to the inspectors during the half year was 2,201; of those arising from other causes, 2,394; there were 292 informations for breaches of the Factory Act, and 213 convictions. The total of the fines inflicted was £317 5s., and the costs £146 4s. 6d.

THE full numerical list and index of the papers laid before the house of Commons and printed in (or belonging to) the Session of 1867 has been issued. The whole number of papers was 1,121. The public Bills of the Session, with the amendments and reprints, fill 6 volumes; reports from committees, 8 volumes; reports from commissioners, 24 volumes; miscellaneous accounts, returns, and papers, 38 volumes; making in all 76 volumes. In the Session of 1867 the House of Commons sat on 128 days, for 1,043 hours in all, 112 of them after midnight; the average time of sitting being as much as eight hours and nine minutes. The House received 12,744 public petitions, with 1,145,216 signatures; divided 164 times; passed 146 public general Acts, and 222 private Acts.

THE New Museum of the Fine Arts Applied to Industry, established in the Strogonow School of Design of Moscow, was inaugurated in April last. The general plan of the Museum was drawn up by M. Boutowsky, on the basis of a plan drawn up for the Lyons Chamber of Commerce by M. Natalis Rondeau, which has been very generally approved. The museum is divided into three sections:—Fine Arts, Industry, and History; and it includes—Collections of Flowers and Plants remarkable for beauty of form or colour, collections of Animals, Birds, and Insects; a cabinet of Drawings and Prints; a special Library of Illustrated Works relating to the Fine Arts; Decorations, Ornaments and Architecture; and an atelier and workshop for the use of the pupils of the school and of the public.

ADVICES from the Sandwich Islands report the occurrence of one of the most terrific volcanic eruptions, accompanied by earthquakes, probably ever recorded. It occurred in Hawaii, in the district of Kona, and the volcano is called Mauna Loa. The earthquakes at times were so violent that no one could stand up; immense precipices were levelled to the earth, and a tidal wave from the sea swept over the tops of the tall cocoa-nut trees. Five villages suffered from the visitation, 80 persons being known to have been killed. The mountain while in eruptirn vomited forth deep streams of lava, which pushed far out into the sea, driving the waters back and agitating them as by a storm. A huge island was thus thrown up, and the streams of smoke issuing from the crater of the volcano enveloped the surrounding country in partial darkness.

THE mean temperature of the air of the Royal Observatory, Greenwich, in the three winter months, December, 1867, to February, 1868, was 39·2deg., being 0·1 higher than the average of the preceding 27 years. The absence of severe cold last winter is shown by the fact that in the summary of returns given by Mr. Glaisher from more than fifty stations in various parts of England no lower temperature is recorded than 14·4deg., which was marked at Lampeter, Cardiganshire, in January last. In the winter of 1866-67 the thermometer both at Lampeter and at Norton-in-Hales, Salop, was as low as zero in January. To find a winter in which the thermometer went no lower than in that just ended we must go back to the winter of 1862-63, which was one of the warmest ever known, the mean temperature at Greenwich of the three winter months being 42·5deg., and the lowest temperature in Mr. Glaisher's list 16·2deg.

DURING the month of January in the current year there were imported to the United States iron amounting in value to 1,299,627 dollars, which consisted of 7,165 tons of pig and 11,841 of bar iron, 57,138 tons of railroad bars or rails, 574,5691b. of anchors, cables, and chains, 2,073,9491b. of sheet and 737,6661b. of hoop iron. The imports also included 4,564,5601b. of lead, 1,926,0201b. of rags, 63,015,1031b. of salt, 66,5931b. of raw silk, 25,523,6671b. of brown sugar, and 1,148,6051b. of molasses, 707,4491b. of tea, wines, spirits, and cordials, amounting in value to 301,031 dollars, 1,038,0411b. of raw and fleece wool, 224,677yds. of carpet, and 4,353,479yds. of dress goods. The imports of bullion and specie, consisting of gold bullion amounting in value to 9,314 dollars, silver bullion to 4,930 dollars, gold coin 512,947, and silver coin to 175,046 dollars.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3245, 3264, 3289
BUILDINGS AND BUILDING MATERIALS—3234
CHEMISTRY AND PHOTOGRAPHY—3232, 3295
CULTIVATION OF THE SOIL, including agricultural implements and machines—None.
ELECTRICAL APPARATUS—None
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3236, 3242, 3249, 3266, 3267, 3278, 3276, 3290, 3292
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—3275, 3307
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—3255, 3272, 3278, 3296, 3298
GENERAL MACHINERY—3228, 3230, 3237, 3246, 3254, 3257, 3260, 3263, 3265, 3268, 3277
LIGHTING, HEATING, AND VENTILATING—None.
METALS, including apparatus for their manufacture—3243, 3282, 3288
MISCELLANEOUS—3229, 3233, 3235, 3238, 3239, 3240, 3244, 3250, 3251, 3252, 3253, 3259, 3262, 3269, 3270, 3271, 3281, 3283, 3285, 3286, 3297, 3300, 3305, 3306
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—3258, 3271, 3274, 3284, 3291, 3294
SHIPS AND BOATS, including their fittings—3231, 3247, 3302
STEAM ENGINES—3279. 3280, 3293, 3299, 3304
WARFARE—3241, 3256, 3278, 3301

3229 A. M. CLARK. *Improvements in apparatus for applying bronze and other powders on paper and other surfaces.* (A communication.) Dated November 14, 1867.

This invention relates to apparatus for applying bronze and other powders on paper or other surfaces with continuous action. The apparatus consists of two vertical frames or uprights, at the upper part of which is mounted a hollow cylinder or drum, having a slit or opening parallel to its axis. Beneath this cylinder is a roller of small size in contact with the upper one, and covered with velvet, flannel, or other suitable material, rotating in a trough containing the bronze or other powder. Opposite the opening in the drum there is placed a table, on which are disposed the sheets of paper, fabric, or other surface to be bronzed; this table has to and fro motion imparted to it, which moves in towards and from the drum at each revolution of the latter, in order that a clip disposed in the slit or opening may seize the sheet at the desired time. The sheets are fed up to the drum in succession, which seizes them one by one, and delivers them to the small roller turning in the trough, which deposits the bronze on the sheet; and the motion of the cylinder being continuous, the said sheet is then brought under the action, first, of a circular brush, driven at a high speed, which removes any superfluous bronze, and afterwards of a series of rubbing surfaces covered with velvet or flannel for fixing and equalizing the bronze powder remaining on the sheet; the paper or other surface continues its motion on the drum until released by the clip, when it is delivered on a receiving table disposed above the one before mentioned. Another sheet is then seized by the clip, and so on. The drum, bronzing roller, brushes, and table are set in motion by means of gearing suitably disposed.—Patent completed.

3230 J. P. L. HECKMANS and F. J. NUNNEY. *Improvements in washing machines.* Dated November 14, 1867.

This invention is not described apart from the drawings. —Patent abandoned.

3231 W. R. LAKE. *Improvements in steering apparatus.* (A communication.) Dated November 14, 1867.

This invention relates to novel and powerful means for controlling and operating the rudder of a steam ship or other vessel, and consists, chiefly, in the combination, with the other parts of the apparatus, of an externally toothed wheel, and an internally toothed wheel or ring, either of which may be attached to the rudder post while the other is fitted upon an eccentric or crank fixed upon the steering wheel shaft or some intermediate shaft connected with the same. A connection with some fixed part of the apparatus or vessel keeps the wheel carried by the eccentric from rotating on its axis, but allows the said wheel to follow the movements of the eccentric as the latter is turned in either direction. Each tooth of this wheel is caused, at each revolution of the eccentric, to act in succession upon all the teeth of the wheel on the rudder head, the rudder being thereby easily turned in either direction. —Patent completed.

3232 J. CLARK and A. ESILMAN. *Improvements in decomposing the sulphides of copper, silver, nickel, cobalt, barium, strontium, and calcium, and in obtaining copper, sulphur, and other products.* Dated November 14, 1867.

This invention consists in treating the materials referred to with persalts of iron, being based on the fact ascertained by the present applicants that the persalts of iron have the property of decomposing the sulphides of the above-mentioned metals, separating sulphur, and forming a salt of the metal of the material operated upon. —Patent abandoned.

3233 R. G. HARCOURT. *Improvements in the manufacture and composition of fire-lighting material.* Dated November 15, 1867.

The ingredients here employed are sawdust, pounded coal, pitch, rosin, gas tar, and paraffin, petroleum, naphtha, or any other volatile mineral or vegetable oil or spirit.—Patent abandoned.

Digitized by Google

3234 P. M. PARSONS. *Improvements in the manufacture of artificial granite suitable for buildings, engineering structures, pavements, and other similar purposes.* (A communication.) Dated November 15, 1867.

Here the inventor employs disintegrated natural granite mixed with clay, together with pounded glass, lava, or iron slags. The disintegrated granite he obtains by submitting fragments of natural granite to a strong heat (about 700deg. or 800deg. Cent.) in an oven or furnace, by which, after a sufficient time, it becomes dissolved into a granitic sand, the constituent parts of which quartz or felspar possess great powers of adhesion. One part of this granite sand is then mixed with about an equal quantity of pounded glass, or the constituents of glass, or lava, or iron slag, or a mixture of all or any of them, to which is added from twenty to thirty parts of refractory clay, or from thirty to fifty parts of ordinary clay; this mixture is thoroughly kneaded together with a sufficient quantity of water to make it of a pasty consistency; it is then moulded to any form required, and submitted to a degree of heat sufficient to vitrify the mass, for about thirty-six hours, which converts it into a hard and durable substance resembling granite.—Patent completed.

3235 G. R. SOLOMON and M. BEBRO. *Improvements applicable to apparatus employed as a ticket register.* Dated November 15, 1867.

This invention relates to a former patent granted to the present inventor, dated September 28, 1867 (No. 2740), and the said apparatus consists in the employment of a box or case containing a continuous strip, ribbon, or roll of tickets, consecutively numbered, which strip is coiled round a central drum or shaft, and the box is locked by an authorized person, so that the collector has no access thereto, excepting to obtain tickets therefrom in the proper manner by the mechanism arranged for the purpose. In the side of the box a slit is provided through which the ticket strip is caused to pass out by means of a knob or handle outside, and a pair of elastic covered feed rollers within the box, which it passes, and which are geared together and provided with a ratchet pawl so as to prevent any reverse motion. The present improvements consist, first, in the adaptation and combination of a dial and finger and gearing to indicate the collective number of tickets issued from the box or case in a certain time; a toothed wheel, forming one of a multiplying train of gearing, is secured to the shaft of one of the elastic delivery rollers, through and by which the consecutively numbered tickets are delivered, and, as the wheels rotate, they actuate a finger beneath, which moves on a dial plate numbered in accordance. Second, the improvements consist in the adaptation and combination of a bell within the box, which is struck by a spring hammer actuated by studs or equivalents, so arranged on one of the said delivery rollers or its shaft that the hammer strikes the bell as the roller rotates at the delivery of every ticket. Third, the improvements consist in combining the whole apparatus constituting the ticket register, or parts with a bag or satchel, so constructed that the box or register may be readily attached or detached; and it has also two pockets or compartments—one locked—into which the tickets, when collected, are to be passed through the slot or opening provided, so that the collector has no further access to them and into the other pocket the money received is to be placed, so that the consecutive numbers of the tickets, the finger and dial, and numbers of collected tickets and the cash in the bag must all correspond, or any informality will be detected. Lastly, the improvements consist in the application and combination of a small lamp with a satchel and other apparatus to enable the ticket distributor to perform his duties correctly at night. The apparatus described for registering either alone or in combination with the dial, bell, satchel, or light may be used and applied for registering the number of persons travelling in vehicles passing in or out of places of amusement or resort, or for any other similar purposes where the number of persons or the number of articles distributed is desired to be ascertained.—Patent completed.

3236 J. CROSSLEY. *Improvements in looms for weaving.* Dated November 15, 1867.

This invention relates to looms for weaving textile fabrics in which different colours or kinds of weft are used, and for which purpose "rising boxes" or change shuttle boxes are employed, and also jacquard apparatus, or other indicating or pattern surface for selecting the kind or colour of weft required; and the object is to simplify the construction, and thereby reduce the friction, and, consequently, the power required for driving the same; also to facilitate the readjustment or rearrangement of the several parts of the loom when the weft becomes used up or broken, the loom having continued in motion for several picks after the occurrence of such deficiency of weft. The invention comprises various arrangements for carrying out these objects.—Paten abandoned.

3237 W. E. GEDGE. *An improved gas engine.* (A communication.) Dated November 15, 1867.

The principle upon which this engine is based consists in the condensation or cooling of the burnt gases after their action on the driving piston. The object of this condensation is to produce the vacuum behind the piston by the construction of the burnt gases.—Patent abandoned.

3238 A. AIRIAU. *An hydraulic clock.* Dated November 15, 1867.

This invention is not described apart from the drawings. —Patent completed.

3239 R. MORSON. *Improvements in keys for locks.* Dated November 15, 1867.

Here the inventor bores the barrel of the key through from end to end, so as to obtain an opening at the rear end of the barrel within the key bow. In a key thus constructed the barrel cannot become choked, as, should any dirt enter it, it is rammed down by the pin of the lock as the key is used, until at last it passes out of the barrel at the back.—Patent abandoned.

3240 L. B. BERTRAM. *An improved tobacco pipe.* Dated November 15, 1867.

This invention consists, chiefly, in providing the bowl of the pipe with an interior cup, which is perforated at the bottom, to communicate with a space in the lower part of the bowl, and is provided with a flange, or number of flanges, to intercept the oil and nicotine, and retain them in the said space while the smoke is drawn into the stem through small apertures or perforations in the said flanges, and through an annular space surrounding the cup, which space is closed by a flange or collar at the top of the bowl. If desired, the perforated flange may be formed around the inside of the bowl, instead of upon the cup, or may be made separately or detached and inserted between the cup and bowl.—Patent completed.

3241 E. FARRINGTON. *An improved tubular cannon.* Dated November 15, 1867.

This invention is not described apart from the drawings. —Patent abandoned.

3242 R. C. ADDY. *Improvements in spinning and twisting frames.* Dated November 15, 1867.

This invention consists in dispensing with the use of the ordinary thread plate, and bringing the thread in a direct line from the delivery roller to the top of the flyer. The flyer consists of two broadened legs, having an eye at the lower extremity of one or both legs, and it is furnished also with an eye at the top in the line of the axis of the spindle, and above the socket of the flyer, and through which eye the thread passes from the delivery roller to the eye at the lower extremity of either of the legs.—Patent abandoned.

3243 A. M. CLARK. *Improvements in refining copper.* (A communication.) Dated November 15, 1867.

The patentee claims, first, the application of air insufflated into the bath of copper for effecting the expeditious refining of copper, as described. Second, the reduction of the silicate of copper by the aid of a mixture of lime and charcoal, or of limestone and charcoal, as described.— Patent completed.

3244 J. TEMPLEMAN. *Improvements in the manufacture of fire-lighters, applicable also for temporary fires or heaters, and in the means or apparatus employed therein.* Dated November 15, 1867.

The patentee claims, first, the manufacture of compressed hard tough fire-lighters, with granular dry combustible body matter, and resinous or pitchy material combined, as a whole generally, and their use, substantially as described. Second, the manufacture of compressed hard tough fire-lighters of a hollow or grooved form or construction, with granular dry combustible body matters, and resinous or pitchy material combined, substantially as described. Third, the construction and use of moulds for the compressing of fire-lighters, and that of the loose lower and upper pressing plates, or ends of the same, for the purpose of removal therefrom along with the compressed fire-lighters, substantially as described.—Patent completed.

3245 R. HOWSON. *An improved gas furnace.* Dated November 15, 1867.

Here the patentee constructs the furnace with a hollow hearth, somewhat like that of an ordinary reverberatory furnace, with one or more flues leading to a chimney. In the corner of the furnace immediately over the hearth he places a pipe or casing, by means of which the gas is introduced through one or more perforations opening downwards, and in the same casing he places one or more nozzles through which air is blown under pressure through the aforesaid perforations. The effect of this arrangement is, that each jet of air causes an induced current of gas to be projected downwards upon the material lying in the hearth, while the air is at the same time intimately mixed with the gas, so that the result is the production of an intense heat in the chamber of the furnace.—Patent completed.

3246 R. HEATHFIELD. *Improvements in machinery for the manufacture of cut nails.* (A communication.) Dated November 15, 1867.

This improved mechanism consists, essentially, of a hollow cylinder having guides through which the nail plate or strip passes, the said hollow cylinder being carried by a table, or rest, or slide, and having a reciprocating rotary motion communicated to it (which motion is communicated to the nail plate or strip) substantially in the ways described and illustrated. Second, the invention consists in the combination with, or the adaptation to, the said turning-over mechanism, of mechanism for feeding or advancing the nail plate or strip to the cutter, substantially in the manner described.—Patent completed.

3247 H. A. BONNEVILLE. *Improvements in apparatus for propelling vessels.* (A communication.) Dated November 16, 1867.

This invention consists in placing at the bottom of ships' boats, and other vessels, along their whole length from stem to stern, and at the lowest part, a cylindrical or such like capacity, the two extremities of which are open at the fore and aft of the vessel. This capacity is divided in the middle of its length by a transversal partition, and the two separate parts are made to communicate by means of a lift and force pump by a steam motive power. The water is sucked up into the capacity in front, and forced from the stern part by means of the pump, and this double action of sucking and forcing propels the ship or vessel.—Patent abandoned.

3249 R. HOLLIDAY. *Improvements in cleansing wool and other similar animal fibres.* Dated November 16, 1867.

This invention relates to the use of hydrocarbon liquors, such as the distillates of coal, tar, petroleum, and paraffin, schist or shale oils, in the cleansing of wool and other animal fibres. In carrying out the improvements the patentee (according to one method) places the fibre to be operated upon in a close vessel supplied with the liquid hydrocarbon (by preference coal tar, naphtha, or petroleum spirit), and when the fibre has become saturated with the liquid hydrocarbon, he allows such liquid to flow from it into a still. He then allows steam under pressure to flow through such tube into a condenser for recovery. After continuing the operation for some time, in proportion to the tar, grease, and dirt contained in the wool and other fibre, he shuts off the hydrocarbon, but continues the steam through the fibre and condenser till all the hydrocarbon is brought over and recovered.—Patent completed.

3250 C. E. BROOMAN. *Improvements in ornamenting bottles and other articles of glass or crystal.* (A communication.(Dated November 16, 1867.

The object here is to ornament or decorate bottles and other articles of glass or crystal. This decoration, which is applied to the exterior of the bottle, has the peculiar property of being diaphanous, and of preserving the transparency of the glass. The ornamentation consists in a special layer of gilding, silvering, or colouring applied to the exterior, and the property just mentioned constitutes a chief point of the invention.—Patent completed.

3251 R. GARBETT. *Improvements in indoor games.* Dated November 16, 1867.

This invention has for its object the adaptation of the ordinary games of American bowls or ten pins, skittles, and nine pins, so that they may be played upon a board or table. For the purpose of American bowls or ten pins the game is played upon a board which the patentee proposes to form of wood, or a slab of slate covered with cloth, and placed horizontally in a frame upon legs or supports, or laid flat upon a table, and with this table are furnished three or more balls and ten pins; the pins are placed in the form of a triangle, or other required shape, at one end of the slab or board, and are played at from the other end, with the balls propelled from a cue or mace. Surrounding the upper end of the board on which the game is played is constructed a trough or margin, or in some instances he prefers to employ bags or pockets to receive dead or fallen pins, or to retain ill-played balls, and the sides of the slab or board are padded to protect the frame; the pin end is raised to prevent the pins from being knocked off the table, and he proposes, if preferred, to form the pins to be used with the improved games in such manner that the resistive power of each pin will be equal to the weight of each ball employed. With some slight modifications he employs similar arrangements to those already specified for the purpose of playing the games of skittles or nine pins upon bagatelle boards or billiard tables.—Patent completed.

3252 A. V. NEWTON. *Improvements in manufacturing and securing envelopes.* (A communication.) Dated November 16, 1867.

This invention relates, first, to a new and improved mode of cutting the envelopes, whereby a saving in paper is effected; and, second, to securing the envelopes by means of eyelets whereby the former cannot possibly be opened and refastened without evidence being left of the fact.— Patent abandoned.

3253 F. W. RUSSELL. *Improvements in cask stands.* Dated November 16, 1867.

This invention relates to means by which the cask may be readily tilted without disturbing the liquid contained. The inventor provides a suitable stand or base, across the top of which near the middle is mounted a bar, the ends of which form trunnions working in bearings in the side frame. This transverse bar forms a lever for tilting cradle placed on the base or stand when the bar is raised, on being partially rotated in its bearings. The cradle is formed of a suitable frame of wood hinged at its front end to the base frame, the rear end being free to rise for the purpose of tilting the cask placed upon said cradle. On one end of the transverse bar projecting from the side frame is fixed a hand lever, by means of which the transverse bar is partially rotated for the purpose above menttoned. This hand lever is fixed on the transverse bar in nearly the same plane with the lever formed thereon, but in the opposite direction, so that when the cask is first placed on the stand, with the cradle resting its whole length upon the base frame, the hand lever will be in a more or less horizontal position alongside the stand, when, by simply depressing the hand lever, the transverse bar will be partially rotated, raising the lever formed thereon, and with it the cradle, thus gradually tilting the cask. The cradle is held in its raised position by the end of the bar taking into a recess made in its underside for the purpose.—Patent abandoned.

3254 C. RITCHIE. *Improvements in apparatus for brushing, combing, cleansing, drying, and perfuming hair.* Dated November 16, 1867.

According to one portion of this invention the inventor employs in brushing hair a bar or axis which is held by the operator in his two hands, one at each end; just within the grasp at one end of the bar or axis a collar or stop is formed, and in a similar position at the other end of the bar or axis is an annular groove. The bar receives upon it a circular brush, a driving drum, and a tubular stop-piece, which slips on to the bar or axis. This stop-piece is secured by a screw which enters into the groove in the bar. The brush, the driving drum, and the stop-piece may be formed together, but it is more convenient to make them separately, and arrange the brush and the driving drum to clutch the one to the other. He employs a flat endless driving band, and he makes the part of the driving drums over which the band passes of elastic or compressible material. In order to render the apparatus applicable for brushing long hair, he applies a small roller (or rollers) parallel to the brush, which roller (or rollers) should be driven at a greater surface speed. The hair, whilst it is brushed, rests or is carried on this roller (or rollers), which, by its rapid motion, keeps it distended, and prevents it lapping around the brush, which is applied between the roller and the head of the person. —Patent abandoned.

3255 R. W. PEARSE. *Improvements in the means of and apparatus for developing or extending the power or sound of pianofortes or other similar keyed instruments.* Dated November 16, 1867.

The patentee claims the construction of the apparatus described, consisting of a hollow foundation or base and sounding-board or bridge, and the other accessories, such as the partitions, sounding posts, and insulated castors, or other insulated supports, applicable to pianofortes or other similar keyed instruments, for the purpose of developing or extending their power or sound.—Patent completed.

3256 J. E. RICHTER. *Improvements in breech-loading fire-arms.* Dated November 16, 1867.

This invention relates to certain improvements in breech-loading firearms, in which the central fire cartridge is used. The opening and closing of the breech is effected by the sliding motion of the plunger backwards and forwards in a line with, and at the rear of, the barrel, the arm requiring only two movements when used, viz., the opening and closing of the breech, which is done by a handle attached to the plunger. The act of drawing back the plunger cocks the hammer and extracts the cartridge, and, a new cartridge being pushed in, the old case is driven out. The act of driving forward the plunger pushes the cartridge forward and into the barrel, and the act of locking the plunger releases the tumbler and discharges the arm, no trigger being required. The details of this invention are voluminous. —Patent abandoned.

3257 J. M. NAPIER. *Improvements in machines for printing calico and other fabrics.* Dated November 16, 1867.

Here the patentee employs in place of "doctors" or "scrapers," wiping rollers having yielding surfaces, and

Digitized by Google

the colour which is removed from the engraved cylinders by such wiping rollers he causes to be transferred to hard rollers or surfaces from which it is gathered by a scraper or doctor. The wiping rollers he prefers to form of india-rubber covered with leather; the india-rubber should be vulcanized.—Patent completed.

3258 W. R. LAKE. *Covering buckles, saddletrees, turrets, hooks, and other metallic trimmings for carriages and harness, with a coating of vulcanized or hard rubber, gutta percha, or other gum.* (A communication.) Dated November 16, 1867.

This invention consists in projecting the various metallic trimmings used upon carriages and harness from rust and tarnishing by covering their surfaces with a coating of vulcanized caoutchouc or hard rubber, gutta-percha, or prepared gum—Patent completed.

3259 W. BAILEY. *An improved system or mode of ornamenting paper hangings, and machinery and apparatus therefor.* Dated November 16, 1867.

Here the ornaments are formed on the paper in leaf or bronze of gold or other metal. For securing the leaf to the paper the inventor employs the size or gum therefor in the form of a powder, or otherwise, and he has the pattern or design to form the ornament, heated when impressed on the paper, all in the usual manner. Heretofore, however, the operation has been intermittent, while in this new mode of manipulation the operation is continuous. He, therefore, has the design or pattern affixed to or carved upon a suitable surface capable of having a continuous motion imparted to it, the simplest form of which is that at the periphery of a cylinder. Such patterns or designs when not carved upon are so attached to the cylinder as to admit of ready removal to give place to others of different design. The paper is caused to pass between this and a similarly moving surface or cylinder, care being taken mechanically to prevent rents or wrinkles in the paper as it enters. He provides each of the two surfaces or cylinders with cogs, or the like, to cause them to move in unison. To make the impression on the paper, one of the cylinders is forced against the other, but undue pressure is prevented by adjustable stops, by which the amount of pressure is limited. He combines with this machinery a heating apparatus consisting of a steam generator, or its equivalent, and in connecting the same with the pattern carrying cylinder he uses joints or "stuffing boxes," one part of which, or of the machine, or of the said connections, is permitted to move or rotate, while the part or parts corresponding therewith remain stationary. He also employs one or more endless "registering" belts to which the paper is temporarily attached when required.—Patent abandoned.

3260 J. G. TONGUE. *Improvements in the process and apparatus employed for ageing and refining wines, alcoholic spirits, and other liquors.* (A communication.) Dated November 16, 1867.

The patentee claims, first, the process, substantially as described, of treating wines or other liquors in vacuo, and under the influence of heat, by agitating it in a distributed form, so as to convert it into a spray, and afterwards circulating the same in a more compact or liquid state in thin layers or streams, essentially as and for the purpose or purposes described. Second, the combination with the vacuum chain of one or more perforated vessels having perforated receiving distributors at or near their top, and agitators operating within them, substantially as described and shown in the drawings. Third, in combination with the vacuum chamber and vessel or vessels, having agitators operating within them, of a series of reversely inclined trays or surface distributors, arranged for operation in connection with the agitators, substantially as described.—Patent completed.

3261 L. and W. BRIERLEY and J. BONNELL. *Certain improvements in the construction of waggons and other carriages employed on railways or tramways.* Dated November 18, 1867.

This invention consists in attaching or connecting the ends of the draw bars together by a link or connection at about the middle of the length of each waggon, and this link or coupling is so arranged that the two screwed extremities of the "draw bars" project sufficiently far through holes provided in the link (one from each end) as to admit of india-rubber rings, or other elastic or yielding surfaces, being inserted, against which a metal washer is placed, the whole being secured and screwed up by means of nuts; a collar or shoulder is formed on the opposite end of the draw bars, just behind the hook, which, when the bars are being screwed up, presses against the outside surfaces of the waggon headstock. By this arrangement it will be seen that the framework of the waggon is released from the strain of traction, which is transferred direct to all the draw bars throughout the train.—Patent abandoned.

3262 R. HUSBAND. *Certain improvements in the manufacture of hats.* Dated November 18, 1867.

In ordinary silk hats the underside of the brim is covered with paramatta, or other cognate material, and the inner edge of the said material is fastened to the inside of the band of the body, without any regard to its appearance there, and is then hidden from view by the leather which forms part of the hat lining. In these improvements the leather does not fit to the band of the body completely round the hat, but at the part intended for the forehead is unsewn, and making an arc shorter in sweep and of larger radius than the corresponding arc of the hat is constructed in scope, so that between the two conterminous front curves—that of the hat and that of the leather—there is enclosed a vacant crescent-shaped space, through which air can pass, as up a flue when the hat is on the head. At this part of the hat the improvements, provide that the inside of the band of the body be finished with a covering like the underside of the brim, and by preference with a continuation of the same covering prolonged over the inside edge of the brim, and finished in like manner, so far as required for sightliness, regard being had to the fact that the open space there between the leather and the body will permit of the covered part being seen. The leather at the part unsewn is fortified by a lining of silk, or linen, or other material cemented on the back thereof.—Patent completed.

3263 E. LORD. *Improvements in machinery for opening and cleaning cotton and other fibrous substances.* Dated November 18, 1867.

This machinery consists of a horizontal beater revolving rapidly within a circular grid, the grate-bars of which are capable of adjustment at one or both ends, so as to increase or reduce the space between the grid and the beater, particularly at the feeding end of the machine. The grate-bars are moved by a plate with spiral grooves, into which their ends enter, and this plate is turned round in either direction by a pinion and wheel; or other equivalent agent may be adopted to move the grate-bars. The fibrous substances are drawn into and through the circular grid by a fan, and a certain space is left between the end of the grid and the case of the fan to allow the fibrous substances escaping with the dirt to be drawn back again into the fan. The fibrous substances are blown over a longitudinal grid, and pass between two perforated cylinders, in which a partial vacuum is formed by another fan. The fibrous substances, thoroughly opened and cleaned, are then delivered on to a creeper which drops them on to the floor, or are formed into lap, either immediately or after passing through one or more beaters.—Patent completed.

3264 C. E. BROOMAN. *A new or improved process of and apparatus or furnaces for the manufacture of metal direct from the ore.* (A communication.) Dated November 18, 1867.

The apparatus employed for carrying out the invention is not described apart from the drawings.—Patent completed.

3265 E. T. HUGHES. *Improvements in knitting machines.* (A communication.) Dated November 18, 1867.

This invention is not described apart from the drawings.—Patent completed.

3266 W., J., and J. BUSFIELD. *Improvements in preparing slivers of wool for spinning and dyeing.* Dated November 18, 1867.

This invention consists in re-winding the silver as taken from the interior of the ball upon a fixed or non-rotary bobbin of equal or nearly equal diameter to the spindle upon which the ball was formed by means of an ordinary spindle and flyer, the bobbin being placed on the lifting rail, and the spindle passing through the bobbin, so that the diameter of the bobbin increases in the same ratio as the diameter of the interior of the ball, or the hole formed therein by the drawing out of the silver. For dyeing purposes a little twist is required to be left in the silver; this the patentees effect by having the bobbin either larger or smaller in diameter than the spindle upon which the ball has been formed.—Patent completed.

3267 W. J. HANSON and J. C. ELLISON. *An improved method of and means or apparatus for dyeing textile fabrics, yarns, and fibrous substances.* Dated November 18, 1867.

This invention consists in the employment of a series of lattice sheets, endless aprons, or "brats" of any suitable material carried on rollers in or through the dyeing vessel, so arranged that two of such endless sheets, aprons, or "brats" will move in contact with each other, and thereby convey and conduct textile fabrics, yarns, or fibrous substances betwixt their surfaces through the dye liquor, and deliver the same betwixt another similar pair of surfaces, and so on through the whole series of surfaces. Or, for the dyeing of hanks of yarn or fibrous substances, the inventors employ two or more rollers for the said hanks to be placed upon or around, and which are caused to rotate in the dye liquor.—Patent abandoned.

3268 J. V. THORNTON and C. ABERCROMBIE. *Improvements in machinery for twisting yarns of two or more colours and kinds, commonly called "French twist" or "Knotted yarn."* Dated November 18, 1867.

This invention relates to machinery for twisting together two or more yarns or threads of different colours or kinds of material, and not in a regular manner, but irregular, so as to produce knots or spots at intervals on the said twisted yarn. To effect this the inventors produce an intermittent motion to either the back or front rollers of spinning or twisting frames, by the application of a cog-wheel having blank spaces, or parts of its circumference without cogs, or by the employment of the well-known star-wheel motion, or other mechanical equivalent means of imparting an intermittent motion to one of the ordinary pairs of rollers, so that one thread may pass betwixt one pair and the other thread betwixt the other pair of rollers, the one thread having continuous and the other intermittent motion. Both yarns pass thence over, through, or by guides placed betwixt the front rollers and the ordinary guide board, and, meeting, are twisted together, the stoppage at intervals of one thread giving time for the other thread to be wound thereon in a knot or spot.—Patent abandoned.

3269 J. COLEBROOK. *A new or improved butter basket.* Dated November 18, 1867.

This invention consists of a holder in the form of a basket or vase of wood, basket-work, or metal, or of electro-plated or gilt metal, with a handle attached. The butter holder is, by preference, formed of glass or porcelain, and is set in the holder by means of a suitable cress, into which it fits; the border of the butter dish, or the holder, is provided with vertical metallic knife rests, across which the butter knife is placed, in order that the basket and butter dish may be moved in conjunction with the knife. The rests may consist of various ornamental devices, allowing spaces for the blade and shoulder or handle of the knife to rest and be secured from falling.—Patent abandoned.

3270 G. FITT. *Improvements in the manufacture of artificial manure.* Dated November 18, 1867.

The patentee claims the manufacture of manure consisting of cinder ash or "breeze," in combination with fatty or oily matters and alkalies, with or without brown acid, substantially as specified.—Patent completed.

3272 T. WOOD. *Improvements in the construction of lamps for burning paraffin, petroleum, or other mineral oils.* Dated November 18, 1867.

This invention is not described apart from the drawings.—Patent completed.

3273 R. WARD and T. TRAVIS. *Improvements in the manufacture of woven fabrics.* Dated November 19, 1867.

This invention is particularly applicable to the manufacture of the cotton fabrics known as velveteens, beaverteens, or moleskins, and consists in making such fabrics with a ribbed face, instead or plain, as heretofore. In performing the invention the patentees employ a loom of the ordinary construction, having four or other greater number of shafts or healds. The invention is not fully described apart from the drawings.—Patent completed.

3274 E. REYNOLDS. *Improvements in the manufacture of wheels for railway carriages and other rolling stock.* Dated November 19, 1867.

This invention has reference to the manufacture of wheels for railway carriages and other rolling stock of cast steel, and consists in first casting the wheel, or, by preference, the skeleton upon which a loose tire is afterwards to be fixed, and whether with spokes or arms or of the disc form approximately to shape, and then working it to the desired form by pressing or stamping in dies, after which, when required, it may be turned or bored to the exact dimensions.—Patent abandoned.

3275 W. J. and A. COLEMAN. *Improvements in the combination and mode of treating and employing certain preparations for various articles of food.* Dated November 19, 1867.

The patentees claim the manufacture of biscuits, lozenges, and similar articles of food, by compounding Liebig's extract of meat with farinaceous materials, then rolling or pressing the mixture together, so as to form sheets or thin pieces, and drying or baking the same.—Patent completed.

3276 H. ENGLISH and J. FARNDON. *Improvements in apparatus for operating the shuttles of looms for weaving narrow fabrics.* Dated November 19, 1867.

Here the parts taking immediate effect on the shuttles in the operation of driving are comprised entirely within the limits of the length of the race, and consist of levers mounted on axes having spur or other gearing taking into a rack bar below, by which the motion is communicated. These levers each consist of two arms of equal length, and diametrically opposite on the axis; the extremity of the arms each terminate in curved branches, spreading in opposite directions, and described of a radius about equal to half the radius of the lever arm. The curved branches are in the plane of the motion given to the levers, and are each provided with a cam groove, which meet in an apex towards the centre of motion; on the back of the shuttle two pegs project which take into these cam grooves, the motion of which causes the shuttle to traverse. During the traverse in one direction, the peg, in its direct motion in the shuttle race, at same time proceeds in the cam groove of one arm of lever (two branches), entering at the extremity of one, and proceeding by the curve towards the conjunction (the apex before-mentioned) with the other, thence passing up that branch from which it escapes. Any form of peg that will traverse the groove may do, but the inventors prefer one of a double wedge form, so as to readily enter the cam grooves, and also to direct its course at their conjunction. Each of the double levers performs about a revolution on its axis, and then reverses for the traverse of the shuttle in both directions, and each operates two shuttles, that is to say, it receives a shuttle on the one side, while it is delivering one on the other; hold of the shuttle on the one side is always taken before it is let go on the other. The invention further consists in providing an arrangement by which the inventors are enabled to operate a double set of shuttles, one set above the other, in two distinct races. The invention comprises other features. The wording of this specification is, to say the least, ambiguous, but we give it as we receive it, rather than run the risk of increasing its ambiguity.—Patent abandoned.

3277 W. ANDERSON. *Improvements in evaporating apparatus, and in utilizing the steam derivable from such apparatus.* Dated November 19, 1867.

This invention relates to a novel arrangement of evaporating apparatus for concentrating solutions, and recovering their chemical ingredients, whereby an economy both in respect of fuel and duration of the apparatus will be secured. The invention further relates to the utilization of the steam generated in the evaporating apparatus, and the employment of the same as a motive power. The liquor to be concentrated is admitted into a closed tank or boiler set above a furnace, the flue from which conducts the flame and heated gases over an incinerating hearth, and under a second closed tank or boiler set above this hearth. The heated gases then pass through a horizontal passage or heating chamber leading to the chimney, upon which is mounted a third boiler. These boilers all communicate by means of steam pipes with a steam chest, say of a condensing engine, into which the steam as it is generated is led off to be utilized. The boilers are fitted with scraping apparatus, which keeps them clean, and thus prevents their rapid destruction. The liquor to be concentrated, say, for example, the black alkaline liquor from straw pulp, is admitted to the closed tanks or boilers, which are in communication with each other by end openings in both the liquor and steam spaces. As this liquor is heated, steam is generated and led off to be utilized, and so soon as the liquor is sufficiently concentrated it is discharged on to the hearth below the second tank or boiler, and the fluid particles remaining are quickly vaporized and driven off by the passing flame. The dry resultant matter then ignites, and when the combustible portion is burnt, a residuum, consisting chiefly of salts of soda, will be obtained. This mode of applying heat, so far as the exposure to the direct action of the flame is concerned, is only applicable to substances not liable to deterioration from contact with the flame and gases of combustion.—Patent completed.

3278 R. A. E. SCOTT. *Improvements in mounting and working ordnance.* Dated November 19, 1867.

The principal object of the present invention is to reduce to a minimum the injurious effect of the firing of heavy guns upon the platform and slide, and also upon weak floors, or upon the decks of vessels. The strain and shock produced on these parts by the firing of heavy guns arises, in a great measure, from the gun being mounted upon so high a carriage that the shock is transferred from the trunnions of the gun to the platform and slide, and thence to the deck at an angle too nearly approaching the vertical. The patentee states that he has discovered that if this angle be lessened, so as to bring the line of strain into a more horizontal position, that the injurious effect of the shock of firing is very much diminished, and hence, by means of these improvements, very heavy guns may be carried by wooden ships, or upon weak floors of batteries, or light upper decks. He effects this by reducing the depth of carriage considerably, and removing the gear below the gun to the outside of the slide, so as to allow the breech of the gun (when firing at an elevation) to pass freely down between the two sides or girders of the slide. The downward shock or strain produced on the platform or slide, and upon the floor or deck by the firing of the gun, is thus reduced by being delivered nearly in the horizontal line. By these means he can safely use cast-iron or other cheap material for the frame of the carriage, and for portions of its machinery.—Patent completed.

3279 A. BARCLAY. *Improvements in motive power engines.* Dated November 19, 1867.

This invention relates, in the first place, to certain improvements in single-acting engines, whereby the consumption of steam, and therefore fuel, is economized, is based upon other inventions, for which letters patent were granted to the present inventor, dated February 22 1861 (No. 453). To effect the economy above referred to,

Digitized by Google

two steam cylinders are employed, one being of much greater capacity than the other. The small cylinder is that into which steam is first admitted; this being let in on the under side of the piston raises it, and when, at the end of the stroke, a valve is opened, by which the steam filling the space on the underside of the piston is admitted to the upper side, whereby the piston descends through the weight or load attached to it, the whole of the steam passing to the upper side of the piston, the part of the cylinder above the piston thus constituting a receiver or reservoir for the steam by which it had been lifted, and wherein it is contained until a fresh upstroke takes place. When the piston has descended to the bottom of its stroke, the admission valves are reversed, and the full pressure of steam again admitted to the underside of the smaller piston; and at the same instant the valve closing the passage between the upper end of the small cylinder and the lower end of the large cylinder is opened, so that the steam contained in the upper side of the small cylinder instantly escapes and expands into steam of a lower pressure in the large cylinder, wherein it acts and lifts the piston therein. The steam, after it has expanded and lifted the larger piston, may escape direct into the condenser; or, in place of passing thereinto at once, it may be passed to the upper side of the piston, thus keeping the cylinder as warm as possible by imparting its own heat to the metal, until the instant a fresh admission on the underside of the piston takes place, when the passage between the upper end of cylinder and the condenser is opened. The second part of this invention relates to the application of a screw and link motion for adjusting the amount of opening of the admission and exhaust valves of this class of engines. For this purpose the link is suspended at one end, and, by turning the adjusting screw, the valve rod or rods to which it is coupled may be shifted to any part of the link, and the amount of throw of the valves thus adjusted.—Patent completed.

3280 E. T. TRENERY. *Improvements in traction engines* Dated November 19, 1867.

Here both the hind and front axles are driving axles, the one deriving its rotary motion from the crank shaft of the engine through the medium of toothed gearing or pitch chains, and the other receiving its motion from the first axle by the intervention of a counter shaft and level gearing. The front axle is made in three lengths jointed together by universal joints, in order to afford facility for its assuming an annular position when turning curves or corners. One of the wheels on each axle is made fast thereon, whilst the wheel on the opposite end of the axle is loose, whereby greater freedom of evolution is obtained. Sometimes the inventor couples one or both of these loose wheels, with their axles, by the aid of a sliding clutch or clutches, in which case he is enabled to have at will two, three, or even four wheels. The steering is effected from the fire-box end of the engine by the aid of a longitudinal rod, worked either by a nut and screw or by a worm wheel and rack, or otherwise, which rod is connected at its front end to a lever arm in a vertical rocking shaft carried in suitable supports at the front of the engine. To the lower end of this shaft there are keyed transversely two horizontal lever arms, each of which is coupled by a link to one end of the front axle, or to pedestals or bearings carrying the axle, such pedestals or bearings being free to slide between suitable guides in the main framing. By moving the longitudinal rod to or fro the rocking shaft will be turned more or less, and the front axle will be caused to assume the angle required, according to the direction in which the engine is to travel. The whole is mounted upon a strong frame, which is extended sufficiently far behind the fire-box to carry a tender containing a supply of coals and water.—Patent abandoned.

3281 C. MOLE. *Improvements in the manufature of soles and heels for boots and shoes.* Dated November 20, 1867.

The patentee claims, first, the insertion of plugs of metal or other material into soles and heels before their application to boots or shoes, not by cutting holes for their reception, but making way for them by displacing the substance of the leather laterally (using the apparatus described, or any other means which may be found available for such purpose), the effect being that the leather itself is rendered closer and less penetrable by moisture. Second, the method described of inserting the plugs by causing them to follow a piercer driven through the leather, and to remain in the opening thus prepared for them.—Patent completed.

3282 W. H. RICHARDSON. *Certain improvements in the manufacture of iron and steel.* Dated November 20, 1867.

This invention relates to four former patents granted to the present patentee, the numbers thereof and the years in which they were granted being as follow:—No. 3189, year 1866; No. 1635, year 1867; No. 1905, year 1867; No. 3226, year 1867. The patentee claims under the present invention, first, the manufacture of improved malleable iron in a direct manner without cooling after the metal leaves the blast furnace, or by purifying re-melted metal in a separate vessel, and afterwards finishing it in a puddling furnace, the metal not being allowed to cool from the time it is first melted, or until finished as malleable iron, as described. Second, purifying crude molten iron in a Bessemer converter, but in place of finishing it therein, stopping the injection of blast or other oxidizing agent before the iron is completely carburized, and in place of casting the purified iron into ingots or moulds from the converter, discharging it into a puddling or other similar furnace, and therein finishing it as malleable iron. Third, the process of manufacturing steel, consisting of refining iron by oxidizing the impurities in a separate vessel, and afterwards treating it in a puddling furnace, and adding carbonaceous matters thereto at any of the points of such manufacture, as described.—Patent completed.

3283 S. COULSON. *Improvements in the manufacture of coffins.* Dated November 20, 1867.

This invention consists in making coffins partly of metal and partly of other materials, so as to form them semi-metallic, or nearly semi-metallic, for which purpose the inventor forms the framework of the bodies, bottoms, or lids, or all of them, of metal, or the bottoms or lids, or both, entirely of metal, which metal, whether as a frame or as a bottom or lid, or partly a bottom or partly a lid, he has made wrought or cast, and made whole, or in parts, or segments, and he has them plain or ornamental, painted, japanned, enamelled, galvanized, bronzed, lacquered, gilded, silvered, or electro-plated. He makes bodies, and also the bottoms and lids (except when he has the bottoms and lids of metal) of timber, paper, clay, porcelain, or glass, or partly of such materials.—Patent abandoned.

3284 H. H. LLOYD. *Improvements in means of communication applied to railway carriages, and in apparatus for making signals, which improvements are in part applicable to other purposes.* Dated November 20, 1867.

This invention consists, under one head, in an improved mode of attaching and employing signal cords for the purpose of ringing signal bells applied to a railway train. We cannot here produce the details of the invention.—Patent abandoned.

3285 T. H. TILLEY. *Improvements in couplings for boring tools.* Dated November 20, 1867.

This invention relates to a novel mode of coupling the rods used in boring earth with each other, and with their bitts or boring instruments. In order to avoid certain well-known difficulties, the patentee makes the coupling rods with a screwed socket at their opposite ends to receive a detached coupling screw, made alike at both ends, and the stem of the bitt or boring instrument he forms with a similar screwed socket, so that, by inserting the screw for (say) one half of its length in one socket, and securing the socket that is to be coupled upon the other end of the screw, a firm and strong coupling is obtained.—Patent completed.

3286 J. OPPENHEIMER. *Improvements in telegraph posts, and in apparatus for fixing the same.* Dated November 20, 1867.

This invention consists, first, in making telegraph posts by joining together a series of tubes of decreasing diameter upwards. To effect this the patentee obtains two iron tubes or pipes, made by drawing or welding in the usual manner, the one smaller than the other, and of such relative diameter that it will not pass into the larger when cold. This larger one he then heats, by which means it becomes expanded, and the smaller tube can then be passed into it. The shrinking of the heated tube for cooling binds the two together. He also shrinks hoops around the aforesaid tubes. To fix the posts they are placed in clamps formed in earth plates, and are held securely therein by screws and nuts.—Patent completed.

3287 H. GREENE. *An improved safety lamp suitable for reading and night purposes.* Dated November 20, 1867.

The patentee claims the application to lamps of an extinguisher capable of being actuated by a stem and handle, or other equivalent means, and also of a mica or talc protector of any suitable form, in conjunction or not with an ornamental or other ring above the chimney, substantially as and for the purposes specified.—Patent completed.

3288 BARONESS C. DE LAVENANT. *Improvements in coating metals and metallic articles for the purpose of protecting or preserving the same from oxidation and decay, also in the materials, machinery, and apparatus to be employed therein.* Dated November 20, 1867.

The inventress claims, first, the use of a base or compound composed of crystal or glass opal, glass borax, minium and carbonate of potash, in the proportions set forth, with or without the admixture of colouring ingredients for the purpose of protecting or preserving metals or metallic articles. Second, the use of the several compounds set forth for imparting to the aforesaid base any desired colour when mixed therewith, and subjected to the action of heat. Third, the peculiar arrangement of furnace, oven, or muffle for glazing, melting, or burning the composition applied to the surface of the meter, or other object described with reference to the drawings. Fourth, the arrangement of waggons or carriers on rails, and machinery for working the same, for conveying the articles to be operated on into and out of the furnace, all substantially as specified.—Patent completed.

3289 J. STAINCLIFFE. *Improvements in smoke consuming apparatus, parts of which improvements are applicable to other purposes.* Dated November 20, 1867.

This invention has for its chief object the consumption of smoke by, in the first instance, withdrawing the gases contained in the furnace flue, and afterwards returning the same to the furnace in a state of combustion, more or less. This result the inventor effects (taking, for example, an ordinary fluid boiler) by placing a chamber or box at the chimney end of the flue, and within it he places a fan of ordinary construction. This fan absorbs, as before named, the gas within the flue, the firing end of which is closed to the outer air. The gases collected by the fan are conveyed in a suitable pipe to the under side of the firebars, and there forced up through the same, the result being that such gases are thoroughly consumed.—Patent abandoned.

3290 W. BREWSTER. *Improvements in apparatus for boiling, washing, or cleansing and dyeing clothes and fabrics, and for other like purposes.* (A communication.) Dated November 20, 1867.

The patentee claims the construction and addition to vessels in which clothes or fabrics are boiled, washed, cleansed, or dyed, of a perforated partition or false bottom, and circulating pipes or tubes, substantially as described and illustrated, whereby a circulation of the water or liquid in the said vessels is set up, and the clothes or fabrics thereby thoroughly washed, cleansed or dyed.—Patent completed.

3291 L. B. JOSEPH. *Improvements in tramways for common roads, and also in wheels for carriages.* Dated November 20, 1867.

Here the patentee makes the tramway of a trough-like form, with the sides of the trough rapidly tapering, so that stones cannot wedge in them, and the rails are sunk so that the surface of the road is flush with the top of the rail, and the trough is made so narrow that the tire of an ordinary road wheel is unable to enter into it. The upper edges of the trough rails are suitably formed to support the wheels running upon them. The rails may be of cast or wrought-iron, or of other material, and they may be laid on longitudinal or transverse sleepers, or by any other method.—Patent completed.

3292 J. OWENS. *Improvements in the manufacture of pile and other fabrics.* Dated November 21, 1867.

This invention is applicable to those pile fabrics in which the pile is produced by floating the weft threads over the warp threads, and then cutting the weft threads, and it consists in an improved mode of weaving, by which the whole of the pile weft appears on the face, and the back is plain or bevelled.—Patent completed.

3293 W. R. LAKE. *Improvements in packing for the piston heads of steam cylinders.* (A communication.) Dated November 21, 1867.

These improvements relate to metallic packing composed of segmental rings which are kept in contact with the surface of the cylinder by the pressure of steam behind them. The improvements consist, chiefly, in the peculiar construction of the segments, whereby each one is fitted to the other in such a manner as to form a continuous steam-tight ring, which lies in a groove in the piston head. This ring is forced outward with a pressure varying with the pressure in the cylinder, and works with the slightest possible friction. Each ring is fitted into a separate groove, and the segments are constructed with tongues and recesses, which may be formed on one side of each segment, or centrally with the same. The steam is admitted into the grooves behind the rings through holes or apertures in the same, or in the piston head. When only one ring is employed, these apertures must be provided with valves. The tongues are rounded or curved from their extremities inward, and the corresponding surface of the recesses is formed and curved in such a manner that the ring may assume an oval shape without breaking the joints or forming a passage for the steam at these parts. A mortice or aperture may be formed through a portion of the segments to diminish the pressure of the same upon the surface of the cylinder, and to receive a light spring which prevents the shaking and rattling of the segments when there is no steam behind the rings.—Patent completed.

3294 G. F. REDFERN. *Improvements in paving.* (A communication.) Dated November 21, 1867.

According to this invention the patentee makes blocks or slabs of small stones, bound or cemented together in moulds of the required sizes, with asphalte or other bituminous cement. These blocks or slabs are laid on a concrete foundation, and can be laid down and taken up from the streets and roads as easily as the flagstones of foot pavements.—Patent abandoned.

3295 J. TOWNSEND. *Improvements in the manufacture of soda and potash.* Dated November 21, 1867.

This invention has for its object the manufacture of soda and potash in a more economical manner than that hitherto in use. It consists in adding to a solution of sulphate of soda or of potash, carbonate of baryta or carbonate of strontia, and lime or magnesia.—Patent completed.

3296 C. BUTLER. *Improvements in lamps for burning liquid volatile hydrocarbons.* Dated November 21, 1867.

In the reservoir containing the volatile oil a conical tube open at both ends is secured, the wide end of the tube being uppermost. The said wide end of the tube is made by preference to fit air-tight in the mouth of the reservoir. The lower narrow end of the tube reaches nearly to the bottom of the reservoir. The lower end of the said tube is filled with cotton wool or other porous material. In the top of the said tube the wick holder is screwed, the lower end of the wick resting on the cotton wool or other porous substance in the tube. The oil in the reservoir is thus cut off from direct communication with the wick, the said oil being transmitted to the wick through the capillary attraction of the cotton wool or other porous substance in the tube. The wick absorbs the oil from the cotton wool, and the cotton wool replenishes itself from the reservoir. By this arrangement the upsetting of the lamp is not attended by the spilling of the oil, and the dangerous accidents which frequently happen with lamps in which volatile oils are burned cannot occur with lamps constructed according to this invention.—Patent abandoned.

3297 S. and B. BARCZINSKY. *Improved means of producing illusory exhibitions.* (A communication.) Dated November 21, 1867.

The inventors employ boxes or casings having portions of their depths provided with a series of slits or openings. Within the box are placed illustrations in varied attitudes or positions of the figures or bodies which it is desired to exhibit. In these illustrations each view of the figure or object to be represented is delineated in an attitude or position modified from that of its neighbour, so that, when the casing is caused to rotate, and the illustrations contained therein are viewed through the slits or apertures, the figures or objects in varied attitudes, being caused, by the rotation of the casing, to pass the eye in rapid succession, convey to observers the effect of animate figures or objects continually moving or changing position.—Patent abandoned.

3298 J. F. WATSON. *The improvement of watches and other timekeepers known as the escapement.* Dated November 21, 1867.

This invention relates to that part of watches and timekeepers known as the escapement; it consists in the construction of a detent or pallet in a manner that has not hitherto been employed. The detent or pallet is made to embrace two or three teeth of the scape wheel; on the outer edge of the detent the scape wheel is locked to prevent the detent from going beyond a certain depth; into the scape wheel a reverse angle to that of the locking which is made on the detent or on the wheel. On the arbor of the detent is an arm about the same length from the centre as the locking. This arm is brought to a fine point, and should stand in a direct line to the balance staff when the wheel is locked. On the balance staff is an unlocking pallet which comes in contact with the arm and unlocks the scape wheel when it falls on the impulse pallet; before it has finally completed the impulse it comes in contact with the inner flange of the detent, and again locks the wheel; on the return of the balance the unlocking pallet moves the arm and brings the tooth of the wheel on the incline plane of the detent, but the force of the wheel brings it back to its original place, and so on.—Patent abandoned.

3299 W. R. GREEN and J. G. FREEMAN. *Improvements in steam and other motive power engines, and in valves for engines.* Dated November 21, 1867.

The patentees claim, first, constructing engines in which the cylinder moves and the piston is stationary, and in which the valves are contained in the piston, substantially as described and represented in the drawings. Second, constructing engines in which the cylinder moves and the piston is stationary, and in which supply and exhaust pipes form guide rods for the movements of the cylinder, substantially as described and represented in the drawings. Third, constructing or arranging valves for engines, substantially as described and represented in the drawings. Fourth, the combination of parts of engines consisting of cylinder, piston, valves, supply pipe, and exhaust pipe, arranged and acting substantially as described and represented in the drawings.—Patent completed.

3300 W. BLUNDELL. *Improvements in cowls or guards for chimneys, and other like purposes.* Dated November 21, 1867.

The primary object of this invention is so to construct cowls or guards as to prevent all draught down the

Digitized by Google

chimneys or shafts to which they are applied. The invention mainly consists in the employment of a conical cap which, no matter how frequently the wind changes, always protects the chimney or shaft on the windward side, but allows free passage for the smoke on the leeward side. The conical cap is fitted or balanced on a spherical bearing or point ball and socket or other suitable joint on the top of a vertical rod carried up from the centre of a crossbar or frame at the upper part of the chimney or shaft, and the length of this rod, and the size of the cap, are so proportioned that the lower part of the cap comes on the windward side below the level of the top of the chimney when acted on by the wind. The cap being balanced on the top of the rod, the side of the cap acted upon by the wind is forced against the side of the chimney, thereby preventing the wind getting down the chimney, or by the pressure of its velocity hindering rapid discharge from the orifice of the chimney, while the opposite side of the cap at the same time rises, leaving an ample opening at the top of the chimney for the egress of smoke. —Patent completed.

3303 E. THOROLD. *Improvements in lamps for burning petroleum and other volatile oils or essences.* Dated November 21, 1867.

We cannot here give space to the voluminous details of this invention.—Patent abandoned.

3304 E. W. HUGHES. *Improvements in rotary engines and pumps.* Dated November 21, 1867.

In constructing rotary engines and pumps the inventor forms a ring which in section is a rectangular trough, having the open side inwards, or towards the centre. Within this ring a drum is fitted, so that its periphery closes the annular trough; the drum is mounted on an axis, so as to be able to rotate. In order that the joint between the two parts may be tight, the drum has flanges on either side overlapping the edge of the trough, in each of which a groove is turned, and the flange overlapping it has a corresponding groove in it. Into one of these grooves a round packing ring of vulcanized india-rubber is fitted, and it is covered with a thin annular plate of steel or other metal. Into the other groove a metal ring is fixed, and it projects so as to bear upon the thin plate, and the elasticity of the india-rubber maintains a close contact between the surfaces; or both of the grooves may contain elastic packing rings covered as above described, and holding the metal ring freely between them. When steam is used in the engine, metallic springs are substituted for the vulcanized india-rubber rings. The thin annular plates are roughened on the underside, so that they may not turn on the india-rubber packing rings. The drum has upon it a piston or stop which accurately fits the annular trough, and closes it so that steam or fluid cannot pass in the trough from one side of the piston or stop to the other. The annular trough also has two or other number of accurately fitting stops in its circumference; they slide in and out to allow the piston or stop on the drum to pass. The axis of the drum is hollow, and the inlet passage for the water or fluid is at one end of it, and the outlet at the other. These passages are continued through an arm of the drum to the periphery, where they open into the annular space close to the piston or stop which the drum carries, and one on either side of it. If the steam or fluid under pressure be supplied at the inlet, it enters the annular space on one side of the piston or stop on the drum, and its pressure acting on this side whilst it is shut off by the sliding stop in the annular trough from acting on the other side, causes the rotation of the drum. The steam or fluid in advance of the piston or stop on the drum escapes by the outlet passage; or conversely, if the fluid is not under pressure and the drum is driven, a vacuum is formed, and the fluid is drawn in at the inlet passage, and expelled at the outlet.—Patent abandoned.

3305 H. JAMES and E. DREWETT. *Improvements in water-closets.* Dated November 21, 1867.

In water-closets as at present constructed, the pan is necessarily open at the top when the valve at the bottom of the pan is open, and, consequently, an escape of foul air results from the opening of the valve. Now according to this invention the patentees arrange the handle, by which the valve of the pan is opened, at one side of the closet, so that it can be acted on when the flap or lid which closes the pan is shut down air-tight, and so as to prevent the escape of any foul gases. In order that the flaps or lids may close perfectly air-tight, an india-rubber seating is provided. Also, according to the invention, immediately under the seat of the closet, and fitting closely to it, and around the pan, they arrange a trough for containing disinfecting material, which at once deodorizes any gases which may issue from the pan on the opening of the valve. Also they ventilate this trough, which, when the flap or lid is shut, forms an enclosed chamber by means of inlet and outlet air pipes, one or both of which may be fitted with valves in connection with the flap or lid, so that, when the flap or lid is open, and the closet in use, the air-pipe or pipes may be closed, but, when the flap or lid is shut down, the air-valve or valves are open to ensure the thorough ventilation of the enclosed chamber around the pan.—Patent completed.

3306 R. LEIGHTON and T. KIRKHAM. *Improvements in the method of sewing sheets of paper forming books and pamphlets, and in machinery for effecting the same.* Dated November 22, 1867.

This invention consists in securing the leaves of the sheet firmly together by a continuous series of stitches along and through the back of each sheet, and at the same time sewing the sheets to tapes or other woven material. —Patent completed.

3307 V. BURCHELL. *A new and improved process and machinery for the manufacture of soda water and other aerated liquids.* Dated November 22, 1867.

We cannot here give space to the voluminous details of this invention.—Patent abandoned.

3308 J. WORMALD and W. B. DALTON. *An improved apparatus by which central-fire breech-loading firearms may be converted into muzzle-loaders at pleasure, and which also forms an indestructible cartridge case.* Dated November 22, 1867.

Where suitable cartridges cannot be procured, a central-fire breech-loading firearm becomes a useless weapon, there being no means of igniting a loose charge or an ordinary muzzle-loading cartridge, and the main object of this invention is to provide an apparatus by which this defect may be obviated. The apparatus consists of a loose or supplementary chamber made out of a solid piece of steel or other hard metal, bored at the one end of an inner diameter, and to a depth suitable to the charge, and, at the other, to receive a nipple, the solid piece dividing the compartment containing the nipple from the chamber which is to receive the charge being pierced with a central hole, tapped for the screwing on of the nipple. In turning this loading chamber to an outer diameter, permitting it to fit closely in the chamber of the firearm, the inventors leave an outer rim at its breech end to permit its easy withdrawal, but they cut away a part of this rim in order that the extractor by which the ordinary cartridge-case is withdrawn may pass the apparatus without extracting it. All kinds of nipples may be used for igniting the charge in the front, centre, or back, but, in order to obtain more room for the charge, they use a nipple of a peculiar construction.—Patent abandoned.

PROVISIONAL PROTECTIONS.

Dated March 10, 1868.

832 R. Cocker, Cockspur-street, Charing-cross, City. Improvements in the treatment of flax, hemp, jute, china grass, and other fibrous materials, and in apparatus to be used therein. (A communication.)

Dated March 14, 1868.

870 N. Jacobsohn, Berlin, Prussia, merchant. A new self-acting letter-box for receipt and payment, provided with a controlling and signalizing apparatus.

Dated April 20, 1868.

1280 L. M. Ruiz, Rue d'Antin, Paris, merchant. Improvements in apparatus for signalling or giving orders on board ships and in other places. (A communication.)

Dated April 29, 1868.

1396 T. and G. Cope, Liverpool, tobacco manufacturers. Improvements in machinery for moulding, pressing, and stamping cavendish and other tobacco into any desired form by suitable die-pieces.

Dated May 2, 1868.

1440 J. Maistre, Ville-neuvette, Department de l'Herault, France, manufactnrer. An improved process for dyeing wool.

Dated May 7, 1868.

1501 K. H. Cornish, South Molton-street, Middlesex. Improvements in the construction of entrenching tools, intended to be applied to firearms.

1503 A. Strauss, Basinghall-street, City, merchant. An improvement in pipes for smoking.

1507 R. Evans, miller, and J. Bruce, engineer, Birmingham. Improvements in machinery or apparatus for dressing millstones.

Dated May 8, 1868.

1509 R. K. Miller, and A. B. Herbert, Edinburgh, and H. Watson, Newcastle-on-Tyne. Improvements in knotters for straining paper pulp.

1510 G. Bowden and J. R. Dickinson, Oxford-street. Improvements in apparatus or means for protecting the points of brushes and pencils.

1511 H. N. Penrice, Wilton House, near Norwich. Improvements in machinery employed in forming tunnels and galleries in rocks.

Dated May 9, 1868.

1519 J. Norman, Glasgow, engineer. Improvements in calcining, burning, or oxidizing ores, minerals, metals, and other substances, and in reducing oxides and salts of metals and other substances, and in apparatus for these purposes.

1521 H. H. Hazard, New Cross-road, Deptford, Kent, and W. Grimwood, North-road, New Cross-road, Kent, engineers. Improvements in coiling or revolving shutters.

1523 R. Waygood, Newington, Surrey. Improvements in stoves for cooking.

1525 W. H. Wilkinson, Southampton-buildings, Chancery-lane. An improved method of combining or uniting types, and constructing cases to contain the same, for the purposes of type composition.

1526 J. H. Crane, Royal Exchange, City, gun maker. Improvements in breech-loading firearms.

1527 G. T. Seydell, Tavistock-place, Tavistock-square, Middlesex, engineer. Improvements in apparatus for heating and ventilating buildings, part of which improvements are also applicable to steam boilers or steam generators.

1528 S. Hall, Swansea, civil engineer. Improvements in the manufacture of artificial fuel.

Dated May 11, 1868.

1530 R. Moore, Glasgow. Improvements in the manufacture or treatment of crushed sugar. (A communication.)

1531 J. Crossley, Heckmondwike, Yorkshire, manager. Improvements in looms for weaving.

1532 W. Webster, whitesmith, and R. W. Barnes, photographic artist, Southport, Lancashire. Improvements in head and waist rests for the use of photographers.

1533 A. D. E. Boucher, Fumay, Departement des Ardennes, France, iron founder. An improved process of moulding hollow metallic pieces provided with a single aperture, such as shells, hollow balls, door knobs, and all articles of the same description.

1535 A. M. Dix, Shelton, Staffordshire, brewer. An improved mode of, and apparatus for, supplying finings or other liquids to casks or other vessels.

1536 C. E. Brooman, Fleet-street, City, patent agent. Improvements in furnaces or heating apparatus. (A communication.)

1537 W. R. Lake, Southampton-buildings, Chancery-lane. An improved device for holding scrubbing brushes. (A communication.)

1540 R. Lecke and J. Beevers, Barnsley, Yorkshire. Improvements in apparatus for the prevention of smoke in steam boiler and other furnaces.

Dated May 12, 1868.

1541 S. Buxton, Southgate-road, Kingsland, Middlesex, clerk. Improvements in writing and printing pens.

1542 T. Briggs, Manchester, tarpauling manufacturer. Improvements in connecting the ends of metal bands for securing bales.

1543 G. A. H. Dean, Ludgate-hill, City, stationer. Improvements in envelopes. (A communication.)

1544 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in fans, and in the method of combining the same with pocket books and other like articles. (A communication.)

1545 T. Pope, Twickenham, Middlesex. An improved curry-comb.

1546 S. P. Armstead, Barnsbury-street, Islington. An improved blow-pipe apparatus.

1547 C. Vero, Atherstone, Warwickshire, hat manufacturer. Improvements in the manufacture of hats or coverings for the head.

1548 T. Shinton, Blaina, near Newport, Monmouthshire. Improvements in forming the ends and joints of pipes.

1549 W. D. Brown, Mains, Turin, Forfarshire. Improvements in reaping and mowing machines.

1550 J. H. Nutt, Kingston-upon-Hull, oil-press, hair, and bagging manufacturer. An improved manufacture of straining surface for oil and other like presses.

Dated May 13, 1868.

1552 S. B. Boulton, King William-street, City. Improvements in the means and apparatus for landing, loading, and conveying timber in timber yards and saw mills, as also in apparatus for facilitating the sawing of such timber.

1553 F. W. and W. J. Crossley, engineers, Manchester. Improvements in machinery for breaking the boon or refuse portion of flax and other plants, and separating it from the fibres thereof.

1554 H. B. Barlow, Manchester. Improvements in apparatus for preventing the incrustation of steam boilers. (A communication.)

1555 G. Dixon, Canonbury, St. Mary, Islington. Improvements in the manufacture of upholsterers' fringes and other trimmings.

1557 S. B. Allen, Boston, Massachusetts, U.S. An improvement in rasps. (A communication.)

1558 C. Farrow, Great Tower-street, City. Improvements in apparatus for cleansing bottles, jars, and casks.

1561 W. Taylor, Woodstock-road, Poplar, Middlesex. Improvements in the construction of iron and steel ships, and in the mode of fixing wood planks to the sides and bottoms thereof to receive the metal sheathing.

1562 W. Baldwin, Blackburn, weaver. Improvements in looms for weaving.

1564 C. Iles, Balsall Heath, Worcestershire, manufacturer. Improvements in the manufacture and ornamenting of thimbles.

1565 R. M. Clunes and F. W. Davis, Worcester. Improvements in harrows.

1566 W. E. Newton, Chancery-lane. Improvements in braces or suspenders. (A communication.)

1567 F. Dixon, Clipstone-street, Middlesex, labourer. Improvements in the construction of packing cases or boxes for holding bottles containing liquids.

1568 W. E. Newton, Chancery-lane. Improvements in axles and axle boxes. (A communication.)

1569 W. Tasker, jun., Waterloo Iron Works, near Andover, Hants. Improvements in steam engines.

Dated May 14, 1868.

1571 H. Marsden and T. H. Blamires, Huddersfield. Improvements in means or apparatus employed in the process of manufacturing wadding or felted fabrics.

1572 W. Gadd, Nottinghamshire, and J. Moore, Manchester, manufacturer. Improvements in looms for weaving.

1573 J. Ashford, black ornament manufacturer, and W. H. Collins, jeweller, Birmingham. Improvements in dress ornaments.

1574 G. de S. Marie, Arcueil, near Paris, manufacturer. An improved mode of colouring or ornamenting capsules, tubes, and metallic foil.

1575 T. B. Kay, Bolton, Lancashire. Certain improvements in carding engines to be employed for carding cotton and other fibrous substances.

1576 O. Konig, Watling-street, City, merchant. A new or improved album or case for exhibiting a series of photographic or other pictures, designs, or drawings. (A communication.)

1577 J. Driver, Keighley, Yorkshire. Improvements in effecting the consumption of smoke and economy of fuel in steam boiler and other furnaces.

1580 W. E. Newton, Chancery-lane. Improvements in the manufacture of felt hats. (A communication.)

1581 W. E. Newton, Chancery-lane. Improvements in steam engines. (A communication.)

1582 V. G. Bell, St. John's Wood, Middlesex, engineer. Improvements in locomotive engines and tenders.

1584 N. Basevi, San Remo, Belgrave-road, Torquay, Devonshire. Improvements in projectiles. (A communication.)

1585 E. Ashworth, Carr Bank, Ramsbottom, Manchester. Improvements in the construction of telescopic rollers for use in machines for drying and tentering fabrics, and for other purposes.

1587 J. G. Walker, Bonnington, Mid Lothian. Improvements in dressing stone, and in the machinery or apparatus employed therefor.

Dated May 15, 1868.

1590 H. C. Crofts, Chatham, Kent, chemist. Improvements in the manufacture of bricks or building blocks.

1591 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of hollow bricks or blocks to be used for the floors, ceilings, and other parts of buildings, and in apparatus for moulding the same. (A communication.)

1592 J. H. Johnson, Lincoln's Inn-fields. Improvements in frames for containing photographs, miniatures, engravings, and other like articles, and in apparatus employed in their manufacture. (A communication.)

1593 J. Hicks, Ifield-road, Fulham-road, Kensington. The application of a method of connecting or disconnecting the bellows, or the bellows and windchest, with the notes or reeds and keyboard in certain musical instruments.

1594 F. Hyde, Hazel-grove, near Stockport, Chester, mill manager. Improvements in the construction of bevel gearing.

1595 T. Singleton, Over Darwen, Lancashire. Improvements in looms for weaving, and in shuttles used therein.

1596 S. Chambers and C. Broadhead, Brightside, Sheffield, engineers. Improved means of preventing the radiation of heat from steam pipes, cylinders, and boilers.

1597 A. Pelard, Passage des Petites Ecuries, Paris, merchant. An improved portable hydrotherapic apparatus.

1598 A. V. Newton, Chancery-lane. Improvements in liquid meters. (A communication.)

1599 J. Robey, Victoria Sugar Refinery, Newcastle-under-Lyme. Improvements in furnaces for consuming smoke.

1600 W. and G. B. Smith, Kennington Park-road, Surrey, gas meter manufacturers. Improvements in dry and wet gas meters.

1601 A. M. Clark, Chancery-lane. Improvements in the permanent way of railways. (A communication.)

1602 W. R. Lake, Southampton-buildings, Chancery-lane. An improved mode of embalming or preserving dead bodies. (A communication.)

1603 J. Price, Dublin, engineer. Improvements in testing the durability and strength of rails, and for ascertain-

Digitized by Google

ing the efficiency of the various parts, forms, and arrangements of permanent way of railways, and in the machinery employed therefor.

Dated May 16, 1868.

1606 H. J. H. King, J. Auchinvole, and A. Patrick, Glasgow. Improvements in gauges or apparatus for ascertaining pressure.

1607 T. Briggs, Street-lane, Ripley, Derbyshire. Machinery for communicating and signalling between passengers, guards, and drivers of railway trains.

1608 A. J. Murray, Albany-road, Camberwell, Surrey. Improvements in reaping machines.

1609 R. Rayner, Lower Clapton, Middlesex. Improvements in apparatus employed for cooking, boiling, melting, and evaporating purposes. (A communication.)

1611 J. A. Adams, Edinburgh. Improvements in cooking ranges.

1612 C. Golden, Bradford, Yorkshire, gun maker. Improvements in breech-loading guns.

1613 W. Allday, Birmingham, bellows manufacturer. Improvements in forge and other bellows.

1614 A. Parkes, Liverpool-street, Birmingham. Improvements in the manufacture of parkesine or compounds of pyroxyline to render such materials more suitable for making billiard balls and for other purposes.

1615 G. Price, Dover-street, Ryde. Improvements in pianos and other keyed musical instruments.

1617 W. E. Gedge, Wellington-street, Strand. An improved process for extracting or removing wool and hair from hides or skins. (A communication.)

Dated May 18, 1868.

1621 E. Billington, Reddish, Lancashire, engineer, and W. Jolley, Heaton Norris, Lancashire, foreman. Improvements in apparatus for conveying and regulating the pressure of steam passing through pipes or other vessels, and taking off condensed water from the same. (Partly a communication.)

1623 G. Watson, Bromley-street, Commercial-road, Middlesex, engineer. Improvements in apparatus for raising and lowering weights.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated May 21, 1868.

1665 C. Chapman, Spurstowe-road, Hackney, Middlesex, master mariner, and J. Lilley, London-street, City, nautical instrument maker. Improvements in instruments used in the navigation of ships.

Dated May 22, 1868.

1693 C. Delafield, Factory Ville, Richmond, New York, U.S. An improvement in furnaces to be used in oxidizing lead, or in the manufacture of litharge.

Dated May 25, 1868.

1721 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in horses' harness. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," June 2, 1868.

175 B. T. Moore. Apparatus for protecting water pipes from injury by frost.

206 C. W. Brown. Construction of truncheons used by police constables.

211 T. V. Lee. Producing charcoal and fuel from peat.

235 T. Cook. Machinery for uniting together materials employed in the manufacture of boots and shoes.

239 H. Hodge. Gas stoves.

240 G. Kirk and W. Murray. Self-acting mules for spinning wool.

241 J. C. Sanders. Door knobs.

246 G. Allibon and A. Manbie. Steam boilers.

251 W. J. Jennings. Permanent way of railways.

254 E. W. de Rusett and R. F. Dale. Water-closets.

263 C. Kilburn. Swimming belts.

265 C. Ritchie. Apparatus for utilizing heat for warming and ventilating.

272 F. Wirth. Apparatus for heating and decomposing water. (A communication.)

284 J. Roberts and J. Morgan. Joining metallic pipes.

294 A. Pickering. Machinery for cutting out and embossing lozenges.

300 A. C. Pilliner and J. C. Hill. Machinery for obtaining motive power.

301 J. H. Johnson. Lithographic printing machines. (A communication.)

302 J. D. Brunton. Machinery for cutting and shaping stone.

325 W. Hartnell and S. Guthrie. Steam engines.

350 J. V. Jones and G. J. Williams. Manufacture of metallic tubes.

351 R. C. Smith. Construction of sinks.

354 A. M. Clark. Utilizing and increasing the lighting power of gases. (A communication.)

355 D. Murray. Coverings for the head.

360 J. and W. Weems. Apparatus for drying grain.

363 J. M. Domenech and F. P. Jonte. Photographic apparatus for outdoor operations.

450 A. M. Clark. Breech-loading ordnance. (A communication.)

453 J. Tansley. Apparatus for working the rollers of blinds.

467 W. E. Newton. Apparatus for saving life in cases of shipwreck. (A communication.)

533 A. M. Clark. Vegetable extract for culinary purposes. (A communication.)

806 W. Hartley. Preparing yarn.

1051 G. Hodgkinson. Method of producing designs upon woven fabrics.

1068 W. J. Addis. Permanent way of railways.

1198 G. T. Bousfield. Dies. (A communication.)

1261 J. Erskine. Breech loading firearms.

1290 J. Woolfield. Machinery for corrugating or fluting sheets of metal.

1343 C. Brown. Apparatus for baking, also applicable to hot pressing.

1439 H. Y. D. Scott. Kilns for burning lime.

1482 C. J. Chubb. Apparatus for getting coal

1488 W. E. Newton. Combs. (A communication.)

1495 M. A. Muir and J. M'Ilwhan. Power looms.

1498 R. A. Green. Bearings, shafts, or pivots applicable to machinery.

1511 H. N. Penrice. Machinery employed in forming tunnels.

1575 T. B. Kay. Carding engines.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 29, 1868.

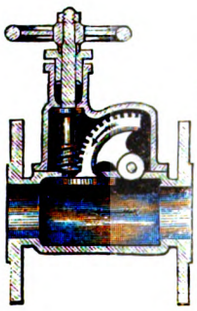
JOHN WARNER AND SONS,

8, CRESCENT, CRIPPLEGATE, LONDON,

Bell and Brass Founders to Her Majesty.



WARNER'S PATENT QUADRANT MOTION SLUICE OR GAS VALVE.

It will be seen by reference to the drawing, that by this simple method a clear water-way is obtained, the disc being drawn by the screw or worm entirely out of the way; thus all the advantages of the ordinary sluice valve are obtained at much less cost, and the liability to set fast and get out of order entirely obviated. They are adapted for all purposes for hot or cold water, and equally suited for high or low pressure, and in case of need of repair a new valve seat can be applied without removing the body or case of the valve.

HYDRAULIC MACHINERY

W. & SONS' Catalogue contains Drawings and Prices of all descriptions of Hydraulic Machinery, Garden Engines, Syringes, Fire Engines, Earthenware, Cocks, Water Closets, General Plumbers' Brass Work, Baths, Bells, Braziery Goods, Lamps, Gas Fittings, and Beer Engines. A 6

WOOD BROTHERS'

PATENT OBLIQUE TRANSVERSE TUBES

For the Flues of Cornish Steam Boilers.

THESE Tubes are exceedingly simple in construction and application, and very durable. They give a greater amount of heating surface than any other transverse tube that can be put in a flue of the same piameter, consequently will generate more steam with greater economy of fuel, and they can be repaired or replaced much more readily than any others.

As these Tubes are put in obliquely, and at a proper inclination, having the flanches at both ends inside the flue, they may be put in or taken out of their places through the flue without passing inside the boiler at all, thus giving the opportunity of applying them to boilers already in use without disturbing them or taking out the flues, whatever be the relative dimensions of the shell and flue.

FOR PRICES, AND A LITHOGRAPH OF THE BOILERS, APPLY TO

WOOD BROTHERS, DON BOILER WORKS, SHEFFIELD.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, JUNE 12, 1868.

THE COST OF OUR SHIPS OF WAR.

IN our impression of March 20 last, we called attention to the absurdity of the method of account-keeping adopted by the Admiralty, in which immense sums of money, designated "incidental expenses" and "establishment charges," are charged to the cost of ships built in our Royal dockyards, whereby Government-built ships are represented as costing over 50 per cent. more than ships built in private establishments. In the one comparison we instituted between the alleged cost of the "Bellerophon" and the "Agincourt," we showed by figures taken from the printed official return that the former vessel, built at Chatham, was charged with no less a sum than £114,424 for "incidental expenses" and "establishment charges." As we know that our criticisms—written, as they always are, in a spirit of reason and fairness—have not previously been void of good results, we intend making a few additional remarks upon this important question.

On reference to the return before us, printed July 22, 1867 (the latest return published), we notice an item of £30,000 for landing, surveying, receiving, depositing, and issuing timber for the several home and foreign dockyards. Now, the distribution of the whole of this item over the ships built and repaired does not offer grounds of fair comparison between the cost of ships built in private and in Government yards. It must be apparent that the large stores of timber kept in our Royal dockyards, on which this additional outlay of £30,000 is expended, is an accumulated stock, and largely in excess of the present demands of the service, whereas but very small stocks of timber are required to be kept in private yards. We cannot in justice accuse the shipbuilding officers of her Majesty's dockyards of mismanagement and want of judgment in accumulating such large stocks of timber as we appear to possess; these immense stores of timber have resulted from the desire of successive Boards of Admiralty to possess the means of greatly increasing our navy in the event of war. There is now, in these days of iron and steel ships, no necessity, if there ever was, for keeping these huge stacks of timber to perform their part in swallowing up the Navy Estimates; no private shipbuilder thinks of purchasing such a stock as we have stacked in our public dockyards, and it is evident that our Government-built ships have to bear a charge in this respect which private-built ships have not.

The next item we notice is an aggregate amount of £56,000 for landing, surveying, receiving, depositing, and issuing stores for the several home and foreign yards. A large portion of this sum is expended on stores supplied for the maintenance of ships in commission and reserve, and it certainly is the reverse of all correct business-views to charge sums so expended to ships repairing and building.

In the return before us, page 23, we find the immense sum of £409,883 1s. 1d. for "establishment charges." This tremendous item is not so explicit as we could desire. It stands as follows:—

	£	s.	d.
For salaries paid for supervision and for establishment contingencies	161,498	3	3
For wages of dockyard craftmen	18,250	15	11
For wages of the Metropolitan Police force employed in the dockyards	30,481	0	0
For freight and sundry charges on naval stores	20,349	7	11
For survey valuations	1,548	3	9
For amount of interest charge for plant	44,787	0	0
For loss on stock ascertained on its re-valuation at the end of the year.	116,981	2	2
For difference between the rate-book value of manufactured articles and the cost at which they have been produced	16,007	8	1
	£409,883	1	1

It is possible that this vast total may comprise charges as little connected with the actual cost of shipbuilding and repairing as with shipwrecking. But however this may be, it is certain that our dockyard establishments are supported on a scale, and maintained in a way, which render it unreasonable to compare them with the scale and manner of private shipbuilding firms.

There is an item of £7,659 for shipping off timber and stores to other dockyards at home and abroad. This is a comparatively small amount, but why it should be charged to ships building and repairing at our home yards we are, as in the other cases, at a loss to divine. There is also a further sum of £8,918 for the preservation and deterioration of timber and stores, the principal part of which outlay is incurred, we should say, from a deliberate State policy, and not from the actual requirements of the existing dockyard works.

We have quoted sufficient figures to show the gross anomalies and unintelligible arrangements which exist in the present system of dockyard, or, rather, Admiralty account-keeping. We do not say, looking to all the objects of our dockyards, that the whole of these expenses are unnecessary, and, therefore, useless and wasteful; but we do say that it is out of all reason to charge these immense and various sums to ships building and repairing in our Royal dockyards; and it is of necessity destructive of a correct basis of comparison between the cost of ships built in our public and private shipbuilding establishments. The blunder of the present system will be immediately seen if we imagine all shipbuilding and large repairs to be excluded from our Royal dockyards. This arrangement would not dispense with our principal home dockyards, nor our eleven dockyards abroad, the cost of which would still go on in refitting and repairing ships in ordinary and commission; but these minor works would have to bear the whole cost of these dockyards, and the apparent cost of these trifling refits and repairs would be enormously increased.

Here is another point deserving attention. It is well known that steam engines of large size are not manufactured in the factories in connection with our Government dockyards, these factories being principally occupied in repairing engines and replacing old or worn-out boilers. The original engines and boilers, being first manufactured by private firms, are not charged with any portion of the cost of maintaining these factories, while the ships building in her Majesty's dockyards are charged with the greater part of them.

It must be manifest that the great and important objects which our Royal dockyards are intended to fulfil, in times both of peace and of war, are not of a description to warrant our semi-naval accountants in charging the whole of these so-called "incidental expenses" and "establishment charges" to the building and repairing of ships. These dockyards are a national institution, intended for the safety and protection of the country at large. Whether they subserve that purpose, or whether we should do better to entirely rely upon private firms, is another question. Be this as it may, it is no part of our purpose to raise a howl for the closing of our Government establishments. There is no doubt upon our minds, from what we have ourselves seen and know, that there always has been, and still is, a shameful waste of the public money in the management of our public dockyards. But this is no reason why we should clamour for their abolition. We ask for their complete reform, not their destruction. We do not see the reason for keeping up the heavy establishment expenses which at present exist. We have no hesitation in objecting to the present naval superintendents and their staff, to a large portion of the existing storekeeping, account-keeping, and clerical staff, to a considerable part of the metropolitan police force, and many other sources of expenditure. We do not say that these services are absolutely useless, looking, as we before observed, to all the objects of our public dockyards, but we do say that they may with safety be curtailed without the least injury to the public service. At any rate, they form no part of the legitimate cost of shipbuilding and repairing. The accounts before us are little better than a huge jumble of words and figures, serving to annoy the faithful critic, but affording little reliable information. It would be well if some member of Parliament were to move for a return of every person employed, together with the salaries they receive, in the account-keeping department of the Royal dockyards and Admiralty. We should then know what we pay for these pretentious accounts, which are, to say the least, like "sounding brass or a tinkling cymbal," signifying nothing.

PHOTOGRAPHY AS AN ART.

THE art-claims of photography do not stand upon a very firm footing, as the most biassed artist-photographers unconsciously admit, by writing so vigorously in defence of those claims. If photography naturally took its position as one of the highest arts, the subject could never have been made a matter of dispute at all, for the bare fact would be so self-evident as to be beyond question. The painter in oil, with trained skill, is able to put the purest and brightest of the ideas floating through his brain, upon canvas. The photographer may have those ideas, yet what can he do? Suppose a lady, with an outline like that of a giraffe, and a face like a pelican, to come into his studio, no artistical taste upon earth will enable him to produce from such a form a "thing of beauty" which shall be a "joy for ever." The photographer may have a perfect idea of the utmost beauty possible in the human leg, but let a real leg be placed before his camera, and the faithful lens will limn the protruding veins, the disfigurements caused by the boot or garter, and many other little matter-of-fact things which the artist in oil is enabled to suppress. Hence hard facts prevent photography from taking a high place as a fine art. The artist with the camera deals with hard facts, but the artist with the brushes deals with the glorious pictures of the imagination.

Yet is good taste and a knowledge of the principles of art, an inestimable boon to the photographer. He can then soften down the peculiarities of nature, and render personal defects less obtrusive. By judiciously arranging his lens for diffusion of focus, he will get rid of freckles on the face; by properly arranging the sitter, he will manage that a nose of vast prominence shall not be taken from a side-face point of view; and he will refuse altogether a lady with black hair who insists upon being taken in a white dress. With gentle words he will persuade those stout old ladies who always carry blue cotton gingham umbrellas not to be taken before a background representing a vast mansion with terraces and marble fountains, and when sitters take their places in an arm chair he will not choose as a background a representation of the free and roaring sea. Where do ordinary people lean against pillars, or convulsively grasp the backs of tall chairs, except in photographs? As a rule, photographers who perpetrate these deeds have no art taste. These are the men who place the arm of the sitter upon the table, and let the hand hang down flat

Digitized by Google

like a flounder, while the eyes stare very hard at nothing, and they have no ideas in their heads to lead them beyond such a performance. The mind of an artist is, strange to say, so visible in his photographs, that sometimes his pictures may be recognized by the art principles alone which they embody.

Children are the greatest nuisances to photographers. The little ones will never sit or stand still; so, if the photographer is not clever enough to keep his chemicals and apparatus in the best order, so as to work nearly instantaneously, so many pictures usually have to be taken that he gains little by a successful issue to his exertions. The same plan is adopted in taking children as in taking horses, that is to say, when the plate is ready for exposure their attention is suddenly arrested by a shrill whistle, or something of the kind, which makes them prick up their ears and keep quiet for a second or two. Sometimes the attention of children must be arrested for a longer time, and the unfortunate photographer is obliged to go behind his camera, then jump up and down and crow like a cock, clapping his hands at the same time, and if these gymnastic performances make the child stare at him steadily without moving, for thirty seconds, that photographer is a happy man, and may find a good likeness on the plate. But photographic faults have a knack of coming more upon these plates than upon others less troublesome to expose, and he probably finds in the picture a broad black comet springing from the nose of the child, so that all the work has to be done over again.

Very frequently it is the fault of the parents, and not of the photographer, that the pictures of their children are unpleasing. They bring the little one, dressed up within an inch of its life, with hair curled with mathematical smoothness and accuracy, the whole resulting in a picture like that of a dressed-up doll. Children have a natural grace of their own, and the less they are artificially ornamented, the more pleasing, as a rule, is the resulting figure. M. Adam Salomon, whose pictures created such excitement at the Paris Exhibition, acts very summarily in cases like that just mentioned. He usually makes the mother take off most of the clothes and artificial trappings of the child, and photographs it very nearly in a state of nature, preferably while lying on a couch and playing with a toy or flower. English mothers would not so readily submit to such dictation, possibly because the education of the people, and, consequently, the public taste, is at a much lower ebb here than in France. This very fact, irrespective of the capabilities of the photographer, is one reason why the Parisians excel us in portraiture.

In landscape photography a taste for the beautiful combined with an accurate knowledge of the powers of his lenses, is a great help to taking good pictures. Wide stretches of open country are seldom pleasing in photographs, except, perhaps, when the operator is so skilled in his art as to be able to secure great fleecy masses of natural clouds. A good foreground is everything in a landscape photograph, and this part of the picture at once shows whether the manipulator is a high-class man or not. In short, there is nothing so easy as to become a bad photographer, or so difficult as to become a good one, and a good taste for high art is one of the essential requisites necessary to raise a photographer above the dead level of those who work with the camera, without sufficient qualifications to do credit to the craft.

NEW PROCESS FOR COATING IRON WITH BRASS AND SILVER.

IT appears that Bavaria is inflicted with patents of impossible processes just as we are. We noticed lately, in our "Notes on Recent Discoveries," a process by one Toderer. His process is for silvering hooks and eyes made of iron wire. Even his process for cleaning the hooks and eyes is unique. He suspends them by means of zinc in a copper vessel containing diluted sulphuric acid until the iron shows a clean surface. In the first place, why a copper vessel? Apparently, it does not assist in producing an electric current, for the zinc and the iron will act as an electric pair, making the iron negative. If the copper vessel were connected with the hooks and eyes, it ought to be by means of iron or copper wire: then the hooks and eyes would be positive, which, we think, would be the most likely way to cleanse the iron in a mineral acid; but apparently that is not the mode, and if it is not, then we should recommend a stoneware pan to contain the acid. After the hooks and eyes are thoroughly cleaned, they are rinsed and placed in a brassing solution composed of a mixture of sulphate of copper, sulphate of zinc, and cyanide of potassium.

We consider this an impossible solution. Of course, these ingredients can be mixed, but the moment they are so, the cyanide and the sulphates will commence to destroy each other, and in the end the solution must be either a sulphate solution or a cyanide solution—it cannot be a mixed one. The addition of the cyanide of potassium to the sulphates would cause a reaction to take place; cyanides of copper and zinc and sulphate of potassium will be produced, and if there be not sufficient cyanide of potassium added to decompose the whole of the sulphate and to dissolve the precipitate, all that will take place will be that the sulphate solution will be deprived of part of its metal, the cyanides of copper and zinc being insoluble in the sulphate solution. But there must be sufficient cyanide to throw down all the metal and to dissolve the precipitate, otherwise brass cannot be deposited from these ingredients, for brass cannot be deposited from a sulphate solution; therefore, really the solution is an impure cyanide solution of zinc and copper. When this solution is pure it is an indifferent brassing solution, and making it in this manner will cause it to be half sulphate of potassium, which will make it still worse.

The proper way to make it is to first prepare the cyanides of copper and zinc, and, after having washed these salts in pure water, dissolve them in an excess of the solution of cyanide of potassium. Though this solution were prepared as carefully as possible, it is one that we certainly should not use for brassing, because the cyanide dissolves the copper twice as rapidly as it does the zinc, and also deposits it in the same ratio. We next come to the silver solution, which is certainly an extraordinary one. It is a mixture of nitrate of silver, cyanide of potassium, and sulphate of soda, which, when the reaction has taken place, will be cyanide of silver, cyanide of potassium, nitrate of potassium, and sulphate of sodium. The real depositing solution in this mixture is cyanide of silver dissolved in cyanide of potassium. The sulphate of sodium and nitrate of potassium are merely impurities which prevent the proper working of the solution. But Dingler says that it "answers all requirements." All we can say is, that the requirements are not great or very particular, or the users of it would have availed themselves of some other process out of the many infinitely superior processes which are already in use, and not have taken the trouble to patent such a hodge-podge as this.

Certainly, we have no room to boast of our superiority in the matter of patents over the Bavarians. Let anyone go to our Patent Office Library and take a day at reading specifications, and we think he will be impressed with the idea, at the end of that day, that our Patent Office is the receptacle for all the absurdities under the sun. But then there are true inventions described in some of these specifications, and one of these is sufficient to redeem the institution from the follies of a thousand of the others. It certainly would be a great advantage if true inventions could be sifted from the pretended ones; but we do not see that it is possible. Who is to decide, in many cases, what is a true invention and what is not? We do not see that any tribunal could be trusted in such a matter, for many real inventions have been denounced as chimerical; for example, Bessemer steel, and Gifford's injector. It is the danger of rejecting such as these that makes us willing to tolerate the perpetration of such folly as we see in the greater number of patents.

THE SOCIETY OF ENGINEERS AT THE MIDLAND RAILWAY WORKS.

THE first of the series of visits by the Society of Engineers, during the present vacation, to public works, was made on Friday last, when the members and associates mustered strongly on the works of the Midland Extension Railway at St. Pancras. The great centre of attraction was, of course, the magnificent roof now in course of erection, which is at present the largest in the world. How long it may remain so we cannot say, as the present fashion of bigness in works of this class is very likely to lead to its eclipse—if only by a few inches. However, this roof is certainly a triumph of engineering skill, and requires to be seen to be realized. We saw the working drawings many months since, but until we examined the structure itself we could not properly conceive its magnitude. In order to convey to our readers some idea of this great work we have illustrated and described it generally in our present number on another page, and shall, in succeeding numbers, give further drawings of the details. It will be, therefore, unnecessary here to do more than refer to the progress of the roof, which was designed by Mr. W. H. Barlow, the consulting engineer of the works. The engineering details of the superstructure were designed by Mr. R. M. Ordish. Mr. F. Campion is the resident engineer of the extension line, the assistant resident engineer being Mr. W. M. Grier, by whom the company were received and courteously conducted over the works on the present occasion. Amongst the members and associates present were Messrs. Baldwin Latham (president), C. J. Light (vice-president), William Adams, John H. Adams, Alfred Williams (honorary secretary and treasurer), Perry F. Nursey (auditor), G. W. Harris (secretary), George W. Allan, Frederick Colyer, Francis E. Houghton, George Waller, John J. Horner, Lewis Olrick, John Pinchbeck, Thomas F. Fillary, W. Lloyd Wise, Henry J. Coles, J. C. Mewburn, Henry Gore, James Knox, F. J. Marshall, James Howard, William Hendry, &c.

The roof is 689ft. 4in. long, 240ft. wide (being 5ft. wider than the timber roof of the Imperial Riding House at Moscow), and 100ft. high at centre from the top side of the girders carrying the platform to the underside of the arched ribs. The total quantity of wrought and cast iron required for this structure is about 6,000 tons, which is supplied by the Butterley Iron Company, who have designed two remarkably fine travelling stages for constructing the roof. The contract price for the roof proper, including iron, slate, glass, and wood, is £120,000, which will, no doubt, be somewhat exceeded before the contract is completed. With regard to the progress of the works, we may observe that fourteen of the main ribs are in place, and a portion of the roof is covered in with slates and glass. The flooring, which is laid with Mallet's wrought-iron buckled plates, is nearly completed.

After inspecting the roof and the station works, the party proceeded down the line to the Agar Town coal depôt, which has been

Digitized by Google

designed and constructed by the proprietor, Mr. Samuel Plimsoll, with the view of facilitating the delivery of coal from the railway to the merchants. The arrangements for economizing time and labour in delivery, and for ensuring a minimum of smalls, are practically perfect, and reflect great credit on Mr. Plimsoll in an engineering point of view. The tramways are carried on an elevated platform or viaduct, along which are thirty shoots through which the coals are delivered into the sacks below, where they are loaded into the vans. There are thirty delivery sheds under the platform corresponding with the number of shoots, and these are rented by the various coal merchants. The coal trucks from the adjoining railway are first placed on a traverser at a point central to the length of the viaduct. The lines of rail have a slight inclination from this point to each end of the works, so that a traverser, with its loaded truck, has only to be started on its course, by horse power, when it continues on its way of itself, being stopped by brakes opposite the shoot for which it is destined. Each shoot is approached by a short line of rails at right angles to the main line, and upon which there is room for three trucks to stand at one time. As soon as a truck is emptied it is pushed beyond the shoot on to another traverser upon a line of rails, by which it is brought up to the centre point again and passed back to the railway. This arrangement permits the operations of delivering coal to the merchants to be carried on without any delay or confusion whatever. The full trucks come on and are moved to the various delivery points, and the empties are drawn off and returned to the railway with rapidity and precision.

The weighing into sacks and loading into vans below is also quickly performed, the tail of the van being close against the weighing machine. The coals are screened as they pass down the shoots by means of screens formed of perforated plates, the holes in which are so arranged that there is no continuous surface down which the slack can run from the trucks into the sack. As already observed, the fracture of the coal is reduced to a minimum, by keeping the shoots always full; a trap door at the bottom of each shoot enables the delivery to be regulated. This saving in breakage is estimated to enhance the value of the coal about 1s. per ton. In short, these works are exceedingly well arranged, and all their details carefully studied. We cannot perhaps give any better proof of their perfectness than by stating that the coal depôt of the Midland station at St. Pancras is arranged on the same principle; in fact, the engineer of the line obtained plans from Mr. Plimsoll, which have been carried out under his superintendence.

The trip concluded by a visit to the Midland Railway goods depôt, which is very extensive and well arranged. A traverser particularly attracted attention, being worked by hydraulic power, and completely under the control of the brakesman, who can start and stop instantly. On the whole, the trip was highly successful, as affording valuable information upon points of engineering in a work of construction, the largest of its kind in the world.

SALT IN FRANCE.

FRANCE is by no means well or cheaply supplied with that great necessity of life—salt. On the contrary, this commodity is comparatively scarce, and therefore dear, besides which it is, as a rule, of very inferior quality. Its scarcity is especially felt in the western parts of France, as evidenced by the fact that while on the east side of that country, the works of Nancy, Dieuze, Salins, Marseilles, and Cette, annually manufacture 550,000 tons of salt, the west only furnishes 150,000 tons. Of this quantity only 10,000 tons are of good quality, being derived from the small works of Salies, Briscous, and Villefranque, and being the produce chiefly of the evaporation of brine springs. The other 140,000 tons are furnished by the Marais Salants de l'Ouest, being the produce of the evaporation of sea-water, and containing 14·20 per cent. of impurity. It must, therefore, be a matter of congratulation with our neighbours to have discovered a deposit of rock salt, of a superior quality, and in the very locality where it is most needed. This discovery has been made in the department of the Landes, near the town of Dax. The salt was first discovered by borings made close to the ramparts of the town, on which occasion the chief government mining engineer, in his official report to the Prefect, stated that a first layer of salt had been pierced of 15 metres (nearly 50ft.) thick. This first layer was subsequently proved to overlie a second one, being only separated from it by a thin layer of saliferous clay. A shaft has been sunk on the spot, and the above-named second layer of salt has been reached. A fresh boring has been executed at about one mile from the first, due south, and within the limits of the concession. Here several layers of rock salt have been pierced, of a total thickness of 131ft.; in fact, the part of the concession now proved to contain salt will furnish about 200 millions of tons, for all practical purposes an inexhaustible quantity. The average composition of the rock salt, as it is brought to surface, will be seen by the following analysis, which has been made by Mr. F. Maxwell Lyte, F.C.S. It shows that the salt, as it comes up in the rough state, contains 97¾rds per cent. of pure salt.

	Parts.
Chloride of sodium (salt) . .	97·6790
Sulphate of lime.	0·4012
Chloride of calcium . . .	0·4588
Chloride of magnesium, Chloride of potassium, Bromine	Trace.
Insoluble residue, clay, siliceous sand, selenite	1·4610
Total . . .	100

Looking at the discovery in a commercial light, there can be no doubt that it presents great attractions for the capitalist. These are enhanced by the circumstance that the deposit is situated at the junction of three lines of rail, on the Chemin de Fer du Midi, one leading north to Bordeaux, 100 miles; another south to Bayonne, 30 miles, and thence to the centre of Spain; and a third east to Pau, and along the chain of the Pyrenees, through the southern departments of France. The Adour, a navigable river, running into the sea at Bayonne, flows through the territory in which the salt was discovered. Taking all these matters into consideration, it is not surprising to find that a company has been formed for purchasing and carrying out a concession of this salt deposit, which has been granted by the French Government upon highly favourable conditions. The objects of the company are twofold. In the first place, they propose to establish salt works which will produce 30,000 tons of refined salt per annum. Fuel—the most important item in the manufacture of salt—is obtainable from large deposits of lignite coal in the neighbournood of Dax, at a very low cost. Labour is also cheap, so that estimates of returns show a very good interest upon the outlay in this respect. Then, the works will include the extraction and sale of rock salt for agricultural and manufacturing purposes, and for exportation, for which purposes salt is exempt from duty. Beyond this, it is proposed, in course of time, to establish chemical works for the manufacture of alkali, bleaching powder, muriatic acid, and the other derivatives of salt, but this extension of operations will be postponed until the manufacture and sale of salt have been brought into thorough working order. Apart from the importance of the discovery to France, in a national point of view, it is of consequence as a means of legitimately employing capital, and we are glad to observe the spirited way in which the matter is being taken up. The development of the salt produce and manufacture in the west of France will not only benefit the country, but will—if carried out as proposed—prove remunerative to private enterprise.

PRACTICAL TELEGRAPHY.

THE value of such a work as Mr. Culley's "Handbook of Practical Telegraphy" * cannot be better shown than by the short time it has taken to arrive at its third editions Of its utility and the way it is appreciated, the fact that it is adopted by the Electric and International Telegraph Company and by the Indian Government Telegraph Department as a text book is ample evidence. It is the exception rather than the rule that works on telegraphic or electrical subjects should extend beyond a first edition. We cannot, therefore, but hail the fact of a book on this technical subject running to a third edition as a proof of the greater interest that is felt now in the science than formerly.

The edition before us is a revision and an enlargement of the previous one. The principal addition appears to be in the appendix, where we find considerable matter that increases the value of the present work. Amongst this matter we may mention a table of "Resistances of a knot-pound of copper wire of varying conductivity, at different temperatures," which cannot but be of great value to all electricians, particularly to those in any way engaged in testing submarine cables—a branch in which the careful testing of the copper conductor for resistance, and for conductivity as compared with pure copper now plays so important a part. The table of squares and logarithms is particularly useful, and to those engaged in out-door work, or any operation where carrying a number of books is undesirable, this addition will be especially welcome, as it will enable them to make difficult calculations easily, and obviate the necessity of always carrying about with them a book of logarithms. Where large multipliers are used, as, for instance, in giving the resistance of the insulation of wires, the use of logarithms is a necessity, and we doubt not that all who use Mr. Culley's book will be grateful to him for supplying them with the means of making those calculations in a more expeditious manner.

The book, as in the previous edition, is full of original and valuable information, carefully culled from standard works, and also contributed by well-known electricians, all of which are in the most praiseworthy manner properly credited to their several authors. Mr. Culley is very particular in this respect, and he states in his preface that he "thanks his friend Mr. Preece for his valuable help, and expresses his obligation to those members of his staff who have so kindly and effectively assisted him." And "he must also thank Mr. Chatterton, Mr. Latimer Clark, Mr. Fuller, Mr. Hooper, Mr. Flemming Jenkins, Mr. Varley, and Sir C. Wheatstone for the information they have so courteously supplied." In this particular respect Mr. Culley sets an example that all authors should be careful to follow, for it may be relied upon that information will be the more likely to be given when it is known that it will be properly acknowledged than when the case is otherwise.

The explanation of rules or laws, or any matter touching difficult or intricate points,

* "A Handbook of Practical Telegraphy." By R. S. CULLEY. Third Edition. London: Longman, Green, Reader, and Dyer. 1868.

Digitized by Google

is always anything but an easy task, however plain and simple the explanation may be; but, from our own experience, nothing is explained so easily, or fixed so indelibly on the mind, as when the information is accompanied with a plain and straightforward diagram. It is in this respect, and in this only, we notice any shortcoming in Mr. Culley's handbook, and we submit for his particular consideration the policy of giving in his next edition more diagrams explanatory of the various points at present without illustration. We believe the policy will be a wise one, rendering the book more valuable and more sought for. When so many excellencies are found collected together, it is difficult to find one more than another that deserves special mention. If we were to make an exception, it would be in favour of the various chapters on testing, in which more varied and useful information will be found collected than can be obtained from any other work.

By publishing such a work Mr. Culley deserves the thanks of all interested in the progress of telegraphy. He places in the hands of the manipulator, of the inspector, in fact of all engaged in telegraphy, a means of accumulating knowledge of the science they are humble workers in. To those unacquainted —as doubtless many are—with any of the mysteries of the science, he places within easy reach a method of making them practically and theoretically acquainted with facts and laws that must of necessity, by increasing their own knowledge, render themselves more valuable not only to themselves but to their employers. To the electrician, to the telegraphist to whatever particular duty he may be assigned, to all interested in telegraphy, we specially recommend the volume before us. To the electrician and telegraphist it will be handy as furnishing facts and memoranda it will be so constantly necessary for him to refer to in his ordinary daily routine. To the scientific man and erudite professor of science it will afford practical examples and facts that may probably prove the correctness of many a well-thought theory. We congratulate Mr. Culley on his rôle as an author, and consider he has done a beneficial act in giving to the world the result of the experiences gained in a life long given up to the study and practical operations of telegraphy.

ENGINEERS AND ARCHITECTS' DIRECTORY.*

THIS is a great book literally, extending as it does to nearly 1,000 pages imperial octavo; as regards paper and printing it is capitally "got up"; but it has merits of a much higher order than those that attach to mere bulk or typography. It is the last addition to the genus Annual, species Directory, and a finer child, or one giving better promise of vigorous life, was never before added to that large family. The publishers, in their preface and elsewhere, modestly bespeak the indulgence of their subscribers and professional friends for any shortcomings that may attach to their first attempt at compiling such a work as they have produced, and profess themselves fully alive to the scope for error—of omission and commission—which it presents. That omissions may have been made may be readily believed, but that wilful sins of either omission or commission have been committed, will not, we think, be alleged. The book contains sufficiently abundant internal evidence of care and impartiality in its preparation to prevent even the suspicion of such faults.

The plan of the book is based upon enlarged and liberal ideas, and, so to speak, the framework leaves nothing to be desired, although the panels may probably, by the help of the trades and professional men interested and appealed to, be more completely filled up in future editions. It must be evident, indeed, that this bold enterprise can only prove successful and the book be made as useful as it ought to be, and as it is capable of being made, by the cordial assistance and co-operation of the professional men most immediately interested. The publishers appear to have done their duty, and it must, to a considerable extent, depend upon the generous co-operation of others whether the publishers' care and cost has been squandered fruitlessly or well applied.

We note the following among the principal features of the book:—A professional directory, comprising an alphabetical classification of architects, sculptors, engineers, surveyors, and constructors of important public works in London, and the chief cities, towns, and places in England, Scotland, and Wales; including a record of noteworthy facts in the professional history of our living architects, engineers, and others, and of those prominently identified with the execution of important public undertakings. And, again, a trades' directory, comprising in one general alphabetical classification of trades the names and addresses of builders, contractors, shipbuilders, and engineers; granite, stone, slate, brick, and timber merchants; metal founders, and of the other industries connected with architecture and engineering in England, Scotland, and Wales. The information collected in this division has only existed hitherto in the diffuse and scattered form of a library of separate city and provincial directories, which could only be consulted at a heavy cost of time and money. The next section of the work consists of an alphabetical list of cities and towns in Great Britain, giving a classified local directory for each place, specially adapted to the requirements of architects, engineers, contractors, builders, shipbuilders, iron and brass founders, stone and metal workers, art workmen, clerks of works, out-door foremen, and other classes of industry connected with construction. The lists in this division are, in some instances, rather meagre, but it will be comparatively easy, the plan being laid down, to supplement them in future editions. Great difficulty attaches to the compilation of such lists, from the fact that there are firms doing very large businesses, as contractors, for instance, who may have a dozen temporary offices in various parts of the country, according to the exigencies of their contracts, and who may not have withal any settled local habitations as firms. The completeness of the lists in all such cases must necessarily depend upon the communication of the necessary information by the firms themselves, to whom a cue may not readily be found by the compilers.

Another division of the book, the place as well as the importance of which should have entitled it to an earlier notice at our hands, is the concise yet comparatively exhaustive account given of the institutions and societies connected with architecture, engineering, and practical science. We do not know of any other single volume which contains, in as compact a form, as full information as is given here concerning these associations.

The classified list of protections to inventions granted in 1867, is novel, and will be useful, we doubt not; but we venture to suggest that in future editions it will be better to give, under a similar classification, which appears to be thoughtfully done, the patents actually sealed, rather than those for which provisional protection has been granted. There is an advantage, doubtless, in the precision secured in taking the applications for the year; and even abandoned patents, although many of them are egregiously foolish, have often a certain degree of scientific interest and value attaching to them; but we submit that, upon the whole, the compilers would economize space with advantage by enumerating the titles of the sealed patents only, even at the expense of sacrificing something in the direction of exactitude in dates and numbers.

The proprietors of this work have engaged upon a delicate and difficult task in entering upon biographical sketches of the principal architects, engineers, and others. They do well, however, in dealing with this part of the volume, to confine themselves very much to statement of facts, rather than to the expression of opinions. A directory is not usually a book from which quotations can be successfully made; in the volume before us there is, however, an embarrassing abundance of quotable matter; but we could neither do justice to ourselves nor to the book by commencing quotations, so forbear altogether. While we have to speak in strong terms of the merits of Messrs. Wymans' work, we are not ignorant of, at least, some of its defects. Notwithstanding these, it is an honest and creditable piece of work, and really a marvel in having so much in it worthy of approval—so many excellencies and so few defects, and those few such as are easily remediable in succeeding editions.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

NEW CEMENTS—COMPOSITION FOR ELECTROTYPE MOULDS—SILICATE PAINT FOR STOVES AND OVENS —PRESERVATICN OF BUILDING MATERIALS.

FEW things are in more constant demand among mechanics than cements, and it must be admitted that most of those in common use are open to improvement. We have recently met with some receipts in the French and German journals, which we put together for the information of our readers. The first is an iron cement, which looks likely to be useful. It is made by mixing from four to five parts of dry clay, two parts of iron filings, one part oxide of manganese, half a part of salt, and half a part of borax. When the cement is wanted for use, this mixture is made with water into a paste, which is applied immediately to the pieces to be joined. It is then allowed to dry gradually, and is subsequently heated to whiteness. After this the cement will resist water, and of course heat. Another, said by Stinde to be a very useful cement, is made by mixing equal parts of oxide of manganese and oxide of zinc, and making them into a thinnish paste with the solution of silicate of soda of commerce. This paste must be applied quickly, as, no doubt, it sets very rapidly. It is not calculated to resist heat and water—the latter, at all events, not for any length of time. Another receipt we find is for a strong liquid glue. To make this the inventor puts three parts of glue with eight parts of cold water, and lets them stand for several hours to soften the glue. He then adds half a part of muriatic acid and three-quarters of a part of sulphate of zinc, and heats the mixture to 185deg. Fah. for ten or twelve hours. The mixture remains liquid after cooling, and is said to be very useful for sticking wood, crockery, and glass together.

The use of gutta-percha for electrotype moulds presents many inconveniences when the medallion or plate to be copied is large. Kness has therefore invented composition for the mould which may be used with articles of any dimensions. It is made by first melting together 6lb. of white wax, 2lb. of asphalte, 2lb. of stearine, and 1lb. of suet. When a homogeneous paste in obtained, he stirs in enough lamp-black to give the whole a deep black colour, and a little very fine plaster of Paris, to give it more body, and prevent it from sticking to the model. When used the pattern must be smeared with a little oil, and the composition poured on at the lowest temperature that it will run well, for if too hot, it will adhere. After cooling it detaches very easily, and forms a hard mould not at all brittle nor likely to get out of shape.

Black lead is a great institution in this country, and probably few but cooks and housemaids would care to see its use diminished. It certainly has its recommendations, but it can hardly be said to be ornamental, while it entails an immense amount

Digitized by Google

of labour on our servants. In Germany, where a stove and sort of kitchen range is continually to be found in the common sitting-room of a respectable family, the unsightliness seems to have been felt, and a suggestion has been made to do away with the black lead and paint the stoves and ovens. Oil paint, of course, cannot be employed, but water-glass (silicate of potash) coloured with pigment to match the paint of the apartment is the material recommended. Before this is applied the iron must be thoroughly cleansed from grease, and all rust spots must be rubbed off with a scratch brush. Two or three coats of the paint may then be put on and allowed to dry, after which the fire may be lighted without fear of injury to the colour, which may, indeed, be heated to redness. Grease or milk spilt over the paint has no effect upon it, and it may be kept clean by washing with soap and water. Dutch ovens and like utensils may also be coated with the same materials, and the labour spent in polishing be saved. A good coating of the paint, the author says, will last a year or two.

M. Payen has paid a good deal of attention to the preservation of building materials, and especially of wood. There is no novelty in his latest suggestion for the superficial carbonization of timber, for we know that it was practised by the Romans. M. Payen, however, recommends that the whole surface of ships should be carbonized, and for this purpose suggests the use of the gas blow-pipe, or, when gas is not at hand, a blow-pipe and lamp fed with heavy petroleum oils. He would treat all woodwork exposed to wet in the same way. The utility of this plan of treatment is incontestable, the only question being whether the same end cannot be gained at less cost.

SUSPENDED RAILWAY WHEELS.

THE disadvantages or defects of ordinary railway wheels are their tendency to mount the rails, and their liability to sliding and lateral concussions, thereby occasioning oscillations of the train, matters which not only engineers but ordinary railway passengers cannot fail to have observed. But, beyond these defects, are loss of power in traction by the unequal wear and tear of the tyres; also unequal expansion and contraction of the tyres and bodies, torsion of the cranks and axles. These defects are greatly increased should the frames of the engine or carriages get out of the square by twisting or straining, leaving out of the question bad roads, unequal lengths of the rails at the various curves, all of which have to be taken into consideration, independently of the straining and vibration of the bridges when passing over, as well as the enlargement of the engine-tyres when they have to be taken off and re-set. There is also the ever-present danger of the tyres, when at high speed, separating or breaking from the body of the wheel, to the destruction of the train, and danger of life, all owing to their being fixed on the axles. These objections are fairly met in a wheel which has been invented by Mr. George Smith, junr., of Donegal-square West, Belfast, and which we here illustrate. Fig. 1 is a half section and half elevation of a portion of the wheel, fig. 2 being an enlarged cross section through the tyre. The novelty of these wheels consists in the body, hoops, spokes, or discs being suspended to the tyres. By such an arrangement the tyres are in compression as well as the body, spokes, or discs, while the hoop is always in tension, the reverse in principle to the constructions at present adopted. Referring to the engraving, A is the tyre into which one of the wrought-iron flanges B is let in and welded over, and the other so arranged as to be removable when required. C is a spring steel or iron hoop, a little larger in diameter than the flanges on B, on which it rests, or the rim of the body of the wheel D, which rests in it. It will be seen that by this arrangement the weight of carriage and body of the wheel D is borne by the steel hoop C, which in its turn is suspended from the top of the wheel by the flanges B B. Thus, any irregularities in the road are compensated for by the play of the steel spring C in the space F.

The advantages presented by this form of wheel are cheapness, lightness, durability, greater safety to the trains, especially at high speeds, as the tyres cannot separate or break from the body, hoops, spokes, or discs of the wheel; nor can they mount the rails. As the tyre sheers instead of biting, there are less jolts, less tear and wear to engines or carriages, and permanent way, no skidding, sliding, or lateral concussions, nor any necessity for double rails at sharp curves. The improvement also prevents torsion to cranks and axles. As the tyres regulate themselves to the irregularities of the permanent way, there will be less straining or vibration of the bridges, on account of the elasticity of these wheels. Lastly, it is found that with these wheels in use, there is no need to loosen the ballast, as is often done, to give elasticity to the rails, so as to lessen the hammering of the rigid wheels as at present constructed. The jolts and jars now felt in going over loose joints of the rails, and especially on bad, rigid, or frozen roads, are greatly prevented—a boon to passengers—especially in long journeys. The arrangement also enhances the safety of the body's spokes, or discs of the wheels, whether made of wrought or cast iron. As they are loosely suspended in elastic steel or iron hoops, they may expand or contract without strain or contortion to the several parts, under all changes of temperature, whereas in the tyre and body of the old wheel there is a constant danger, in consequence of their unequal expansion

FIG. 1

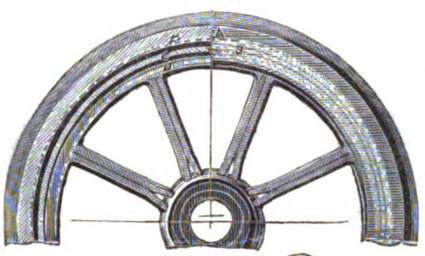

FIG. 2

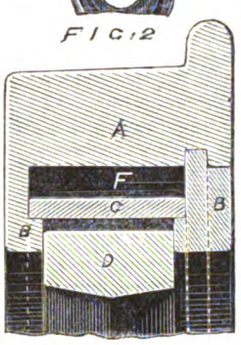

and contraction, more particularly in sudden changes of the weather. A set of four of these wheels have been running on the Great Western Railway over eleven months under a high-sided goods truck, which, when laden, weighed over seventeen tons, thus giving four and a-quarter tons per wheel. When the inspection took place on May 6 last, these wheels—which have done many thousand miles of work—showed little or no wear, whereas tyres of the same quality of steel and running from the same date and the same distance showed a diminution in the thickness of the tyre on the tread fully equal to $\frac{1}{4}$in. The North London Railway Company have also had some of these wheels in use for more than a year, and we are glad to say they are there giving every satisfaction.

ROYAL CORNWALL POLYTECHNIC SOCIETY.

WE append a list of premiums and prizes in the mechanical department for 1868, offered by the Council of the above useful institution. The mechanical department includes natural philosophy, chemical analysis, mechanical and other scientific inventions and improvements; models of machinery not displaying invention; and naval architecture — in all of which subjects medals and prizes will be awarded by the Society. The special premiums are as follow:—Premiums of £10 for the best model, and £5 for the best plan for improving the ventilation of mines. A premium of £20, by the editor of the "Mining Journal" and by the Society (or such portion thereof as the judges shall consider suitable), to the originator of, improvements in the dressing of ore, such improvements to have been in successful operation for a period of not less than six months. A premium of £5, by the editor of the "Mining Journal," for the best paper containing an account of any methods or plans practised in any other mining districts, advantageously applicable to the Cornish mines; to be accompanied by the necessary drawings. A premium of £2, by the Society, and £3, by Colonel Tremaine, for the most exact account of the phenomena of mineral veins in any mine or district, their dip, direction, variations in productiveness, slides, heaves, &c. The Society being especially desirous of cultivating close habits of observation in our miners, will give prizes for accurately drawn cross sections; for collections of ore and country in which the relations of one to the other are carefully marked; for drawings and descriptions of any remarkable phenomena observed in lodes, &c. The introduction of improved methods of drawing the ores and rubbish from the Cornish mines appears to the committee to be worthy of attention with reference to these premiums. A premium of £5 5s. is given by the Society, for the best working plan of a mine in full work (sections of the lodes not required); the plan to be corrected to some time within three months previous to its exhibition, and to be drawn by the person who dialled the mine-workings.

The following has been forwarded by Charles Fox, Esq:—The value of copper ore in any state is soon ascertained, and unless of very low produce, can bear the expense of carriage. Tin-stuff, when in considerable quantities, requires more investigation to judge of its value. In many parts of the county, purchasers of it in the stone are not to be met with, whilst the expense of carriage to stamps (if the use of any be attainable) may be too heavy an item in the returning charges. This also applies to some copper halvans and skimpings. I therefore offer premiums of three, two, and one guineas, for the first, second, and third-class models of steam stamps (to possess a stamping power equivalent to that of three or four heads) which may be removable from place to place, whether attached to wheels or on frames, to be transported on a waggon. Or for such improvements, especially in the stamping part, in steam stamps, whether stationary or locomotive, as may simplify the machinery, whether of the engine or of the stamps, without impairing its efficiency. Should the judges be unable to decide that such alterations are, on the whole, an undoubted improvement, the premium should be considered as earned, if they recommend them as clearly deserving of trial.

A premium of £1 is offered by Mr. R. R. Broad, and £2 by the Society, for the best practical essay on the improvement of Cornish river fisheries, especially with reference to salmon. An additional premium of £1 by Mr. R. R. Broad, and £1 by the Society, will be awarded if the suggestions are carried into effect. Finally, there is offered a prize, by the editor of the "Mining Journal," of Burgh's large folio of "Practical Illustrations of Steam Boilers and Engines," with pocket-book of practical rules for the same, for the best (original) mechanical drawing by youths not receiving another prize. Premiums are also offered in the fine arts, photography, &c. We should add that further information respecting the Society generally, and the above objects in particular, may be obtained from the acting hon. secretaries, W. P. Dymond, Esq., and A. Lloyd Fox, Esq., Polytechnic-hall, Falmouth; or from Mr. J. C. Stephens, the manager of the Art Union of Cornwall.

SILKWORMS' EGGS.

THE Italian correspondent of the "Times" writes as follows:—You are aware that of late years there has been a very large importation of silkworms' eggs from Japan to Italy, with a view to repairing the ravages of disease among the worms in this country. To a considerable extent the plan has proved successful, although the descendants of the Japanese by no means invariably escape—at least, in the second and third generation—the mysterious affliction which has long played such havoc with one of the most important and lucrative of Italian productions. Latterly, complaints have been heard even of the eggs imported direct from Japan. To all appearance they were of good quality, but it seemed they were not proof against the prevailing epidemic. A circular that has just been addressed to the presidents of agricultural committees, by the Minister of Agriculture and Commerce, accounts otherwise for the deterioration. A system of fraud has been detected. The Minister declares it to have come to his knowledge that a great number of cases containing empty papers of the kind in which the Japanese eggs are usually sent, have been received by a Milan house. These papers are duly stamped and inscribed in Japanese; they bear the Custom-House mark usually put on them at Yeddo on their way to the Yokohama market. The Minister declares it beyond a doubt that these papers were intended to receive Italian eggs, which would be sold to the public as genuine Japanese—thus discrediting the only eggs on which is now based a hope of reviving sericulture in this country. The discovery appears to have been due to the refusal of certain Japanese houses to submit their papers of eggs to the inspection and stamp of the Italian agents and consuls in Japan. The Minister promises great vigilance to defeat these frauds, for, he adds, he has reason to believe that other persons are on the alert to follow the example of the Milan house above alluded to. According to an official publication, in 1863, the total value of the cocoons produced in the provinces which now compose the kingdom of Italy was upwards of four millions sterling. To obtain this there had been imported 56,129 kilogrammes of eggs, at a cost of twenty-four millions of francs, or nearly a milloin sterling.

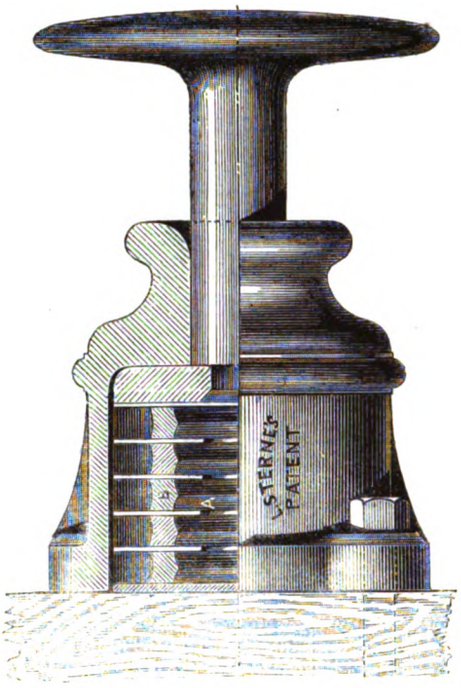
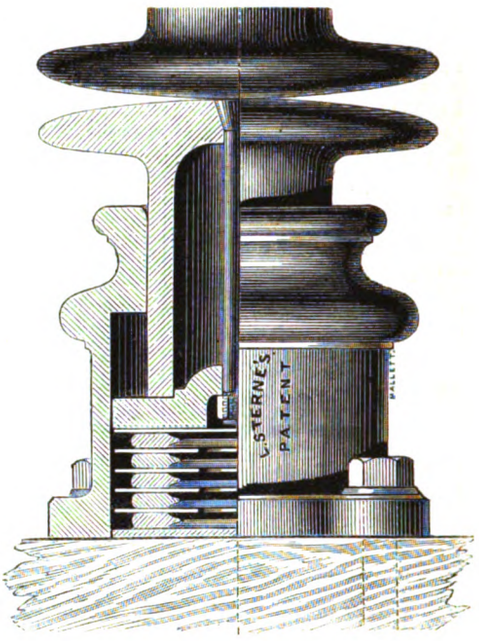
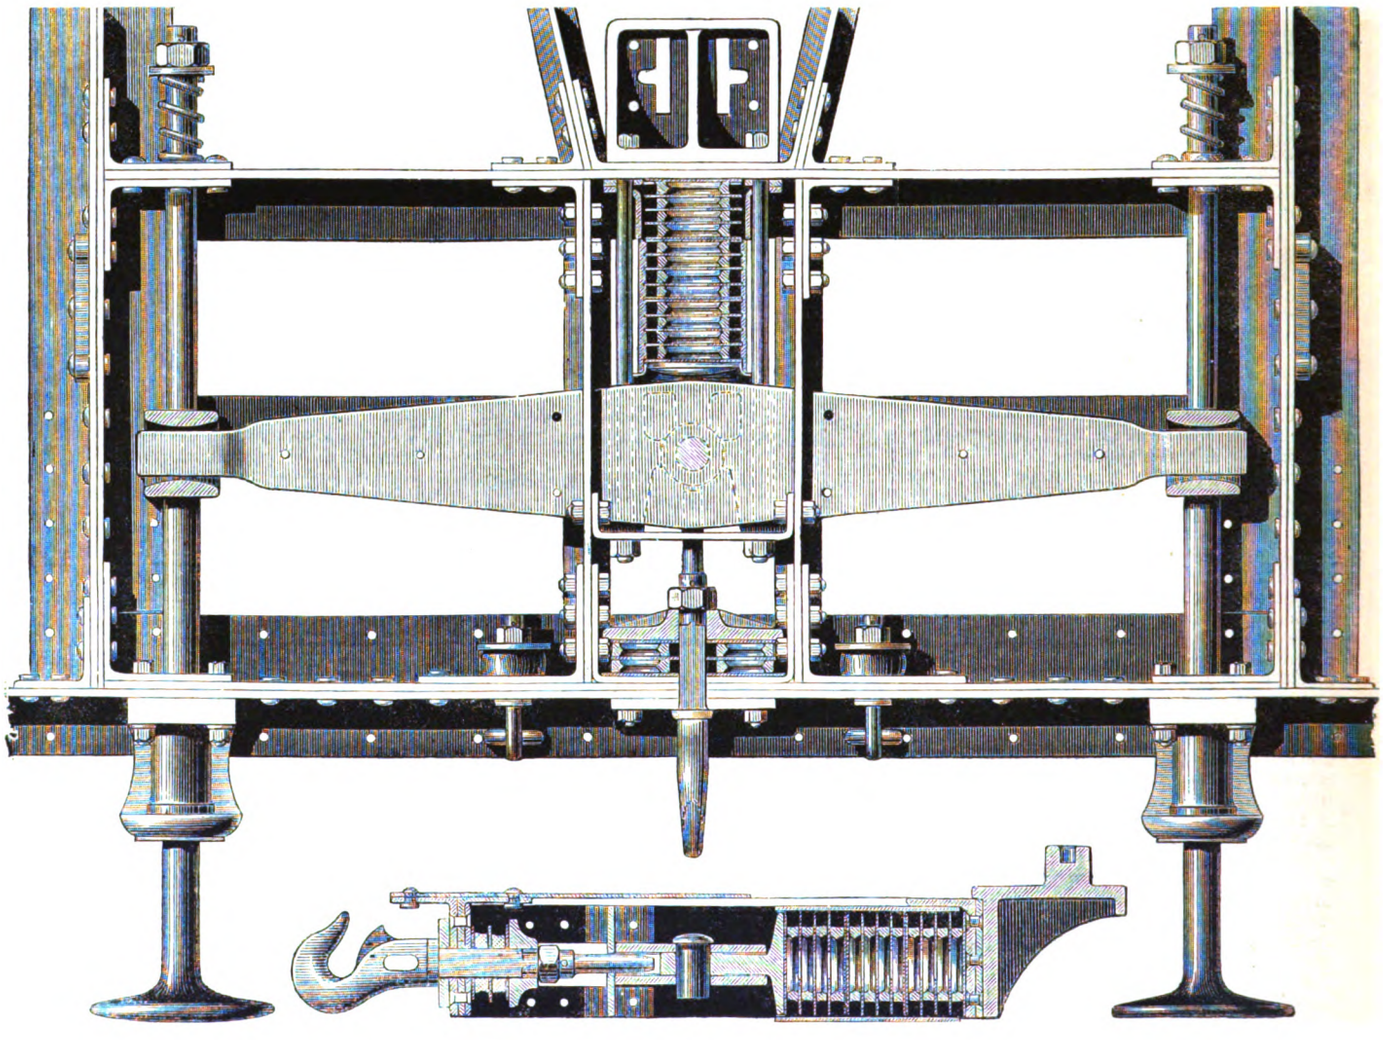
PNEUMATIC RUBBER BUFFERS, BEARING AND DRAWING SPRINGS.

BY MR. L. STERNE.







Digitized by Google

PNEUMATIC RUBBER BUFFERS AND DRAW SPRINGS.

IN our notice of the conversazione of the Institution of Civil Engineers we referred in passing to the pneumatic rubber buffers and draw springs exhibited by Mr. Louis Sterne, of No. 8, Great Queen-street, Westminster. We now have much pleasure in illustrating this invention, which is being adopted with thorough success in several lines of railway, and is no longer an experiment. The buffers and springs, as shown in our engraving, are built up of soft india-rubber rings and circular steel, iron, brass, or other metal plates; the terminal plates of each spring being complete discs, while the others have each a hole through the centre. During the process of vulcanization the buffer rings become inseparably united with the plates, and each spring thus becomes a perfectly air-tight chamber. When pressure is brought to bear on the springs the air within them becomes compressed and offers a resistance proportionate to the amount of such compression, and to the area of the discs upon which the pressure of the air is exerted. The india-rubber rings not only perform the office of securely retaining the air within them, but resist sudden concussions better than any rubber buffers ordinarily used. In order to avoid friction upon the rubber, by which it would be quickly destroyed, the circular plates are extended beyond the rings to a distance in proportion to the depth of these rubber rings. The india-rubber, therefore, can never be injured or come in contact with the inner surface of the cylinder. Fig. 1 represents the buffer at rest, and fig. 2 compressed in action.

In practice it is found that these buffers are capable of resisting more compressive force than a steel spring, possessing greater sensitiveness, and all liability to accident from breakage is completely avoided. Unlike a steel spring, which, if made to resist great force, is rigid until a considerable weight is brought to bear upon it, this buffer spring is sensitive to a very slight pressure, and yet absorbs a power of 14 tons, being 100 per cent. more than the resisting power of any steel springs used for this purpose. These buffers may fairly be said to possess greater resisting power, greater sensitiveness and range of elasticity, combined with great freedom of action, simplicity of construction, ease of adjustment, and undoubted durability than any others. They are in use on the Great Western, London and South Western, Metropolitan, Great Southern and Western of Ireland, the Scinde and Delhi, Great Southern of India, and other lines of railway at home and abroad.

At fig. 3 of our engraving we show the application of these springs as buffers and draw springs, as adopted by the Metropolitan Railway Company. Each buffer rod carries a kind of shoe embracing the ends of a compensating travelling beam, which extends from one spindle to the other. This transmits the pressure fairly to the springs, at the same time enabling the buffer rods to accommodate themselves freely to the position of the carriages passing round curves. The buffing spring occupies a length of 13½in. when uncompressed, and is capable of being compressed 9in. The light spiral springs at the end of the buffer spindles are merely placed there to prevent chattering. The draw-spring is formed by a pair of pneumatic springs placed one on each side of the draw-bar, and composed of two rings of rubber each.

Some important experiments were recently made by Mr. Kirkaldy with Mr. Sterne's buffing apparatus, to show their resistance, the results of which we append. The following tabulated statement gives the results of experiments to ascertain resistance to depression under a gradually increased thrusting stress of seven of these buffer springs.

Tested in cast-iron case, with wrought-iron plunger.—The above depressions are each the mean of four readings.

Whilst on this subject, we may add the results of some experiments made by Mr. Kirkaldy to ascertain the resistance to depression under a gradually increased thrusting stress of Mr. Sterne's rubber washer for armour-plate bolts:—

Stress in pounds.....	4·000	8·000	12·000	16·000	20·000	24·000	28·000	32·000	36·000	40·000	44·000	48·000	52·000	56·000	60·000	64·000	68·000
Depression, inches.....	·283	·504	·615	·702	·755	·800	·830	·854	·875	·891	·903	·919	·931	·944	·958	·972	·984

RESULTS OF EXPERIMENTS to Ascertain the Resistance to Depression under a Gradually Increased Thrusting Stress of two of L. Sterne's Patent Pneumatic Rubber Buffers in Cases:—

Test Number.	Description.	Tested.	STRESS IN POUNDS, AND DEPRESSION IN INCHES. 1,000	2,000	3,000	4,000	5,000	6,000	7,000	8,000	9,000	10,000
C 254	Five Rubber Rings.	March 21	1·02	1·60	1·91	2·04	2·17	2·26	2·32	2·40	2·48	2·51
255	"	"	1·07	1·62	1·94	2·10	2·18	2·28	2·36	2·43	2·49	2·53

The above depressions are each the mean of four observations.

With these satisfactory results we cannot doubt the ultimate general adoption of this principle of pneumatic buffers and springs.

FORTIFICATIONS.

THE following instructions, signed by Sir J. Pakington, for the guidance of the committee recently appointed to inquire into the construction, condition, and cost of fortifications, have been issued as a Parliamentary paper:—It appears to me extremely desirable (having reference to questions recently raised in the House of Commons) that a full inquiry should be made into the construction, condition, and cost of the fortifications and works erected, or in the course of erection, under the 30 and 31 Vict. c. 145, and previous statutes, by a competent committee. I have the honour to inform you that the officers and gentlemen named in the margin have consented to undertake such inquiry, under your presidency, and to report to me the result. Plans of the works in course of construction will be laid before you; and, accepting as approved the position of the forts, and the general design of the works, the matters upon which I desire the information and the opinion of the committee are—1. Whether these forts and works have been well and skilfully constructed, with reference —(.) To their stability and permanency. (*b.*) To the arrangements made, or proposed to be made, in them for the service of the guns, and otherwise to meet the requirements of a modern armament. (*c.*) To the power of resistance (offensive and defensive) that they offer to any attack to which they may be exposed. (*d.*) To the cost incurred and to the future expenditure that may be needed for their completion (if this inquiry can be readily accomplished by the committee, and without involving them in a considerable sacrifice of time). 2. Whether any and which of the works, so far as the same have yet proceeded, are, with reference to their foundations, or otherwise, in an insecure condition, and need any and what support or reparation, and what would be the probable cost of such support or reparation. 3. Whether the estimates in the schedule of the Fortification Act of 1867, before referred to, will suffice for the completion of the works as contemplated, and, if not, what additional sums will probably be required. 4. For the purpose of enabling you to carry out this inquiry, I have requested his Royal Highness the Field Marshal Commanding in Chief to cause the general officers commanding at the stations to be instructed to give the committee all requisite facilities. I have also desired the officers of the War Department to give you the fullest information upon every matter upon which the members of the committee may require it; and I have to express a hope that the inquiry will be conducted with as little delay as may be compatible with full investigation and report, and that the committee will, if they deem it to be expedient, make a preliminary report on any of the subjects of inquiry.

THE HANDEL FESTIVAL.

THE grand triennial festival which takes place next week at the Crystal Palace will be held under improved conditions. Various alterations have been made in the Handel orchestra, and the great transept has been enclosed with screens, thus forming a magnificent concert hall, possessing a power of concentrating sound far greater than has ever been previously attained at the Palace festivals. For the comfort of the visitors a very wise precaution has been taken in having the roof covered on the outside to screen it from the heat of the sun, proper ventilation being at the same time effectually provided. The stage of the theatre fronting the Handel orchestra is being fitted up with Royal boxes, a reception room, floral parterres with fountains and sculpture, as on the occasion of the visit of the Sultan last year. An important feature is the increase of railway facilities since the last festival—the different points of departure and the additional service in this respect being now amply sufficient for the conveyance to and fro of the maximum amount of expected visitors without delay or embarrassment. Everything, as far as arrangements are concerned, promises to render the Handel Festival of 1868 a thorough success.

THE Prussian Reichsrath has voted a sum of £900 to defray the cost of a scientific mission to Aden to observe the eclipse of the sun on the 18th of August.

THE MIDLAND RAILWAY EXTENSION WORKS.

THE visit of the Society of Engineers to the St. Pancras Station of the Midland Railway, on Friday last, as noticed on another page, afforded us an opportunity of looking over the works generally, and of placing before our readers drawings and particulars of the same. For this purpose we will commence at a point about two miles from the London terminus, and follow the course of the line until we arrive at the St. Pancras station, where the line terminates. The railway is constructed for four lines of way for a considerably further distance than we have named, and at the point from which we started it emerges from under the Hampstead Junction Railway, which line is carried by a heavy brick viaduct of two arches. On the east side of the line, near the bridge, are large engine sheds, fitting shops, blacksmiths' shops, and other buildings necessary for the repair and fitting-up of locomotives. The line then passes under the Kentish Town-road, through a double-arched bridge, the crown of which was roofed in with cast-iron plates, so that the requisite headway might be obtained without disturbing the levels of the road. The site of the Kentish Town station is in this arched bridge, and substantial retaining walls are built on either side the line through the cutting. The line then passes under Hammond-street, Islip-street, Caversham-road, and Gaisford-street, through brick arches. We then arrive at the site of the Camden-road station, the building of which is situate on the top of the covered way near the Camden-road. The arch of this covered way is elliptical and built of five-ring work. At the south end of this covered way the lines commence to widen out, and at the junction of Paul's-road, St. Augustin's-road, and Murray-street, which are carried by a wide bridge of wrought-iron girders, with brick arches between them, the several lines begin to assume their distinctive character. The main lines go direct to the terminus, while the St. Pancras branch leaves the main line on the east side, and the several other lines which will serve the existing goods station diverge to the west; all these lines are carried under the North London Railway, near Camden Town station, by bridges of various construction, those for the main lines being composed of wrought-iron girders and planking, and that for the St. Pancras branch by a brick arch or tunnel. We will follow the course of the main line to the terminus first, and then give a description of the Pancras branch, or that portion of the line which will connect the Metropolitan line with the great system of the Midland Railway.

After passing under the North London Railway the main line runs alongside the existing goods station and crosses over the Regent's Canal and Cambridge-street, by wrought-iron girders and platforms, and then arrives at the Old St. Pancras burial ground. Here the bridge which carries the railway is in three spans, and is supported on brick abutments and piers formed of cast-iron cylinders built in segments and bolted together. These cylinders are well sunk in the blue clay, and are filled in with concrete and brickwork. After the brickwork had set each pier was tested with loads varying from 200 to 300 tons, and, after the load was removed, large stones of Bramley Fall were fitted to the cylinders, and the superstructure was then proceeded with. After passing over the burial ground the line is carried in brick arches of 25ft. span until it intersects the Old St. Pancras-road, where it joins Brewer-street, Wharf-road, and Elstree-street. The arching carries the sheds necessary for railway carriages and other requirements which are requisite at a large terminus, for the making up of trains, such as turntables, shunting sidings, &c. These arches will no doubt prove valuable property, being available for storage of goods, &c., and, having a good frontage in the Old St. Pancras-road, will probably be made use of by the public. At the extremity of this arching the line is carried over the Old St. Pancras-road by wrought-iron bridges varying in span, and widening out to suit the position of the lines going into the terminus.

We now come to the St. Pancras terminus, at the entrance of which the rail level is 17½ft. above that of the road and the adjoining streets. At the frontage the height is 12ft. above the Euston-road. The opportunity thus opened was taken advantage of, and the space afforded by these levels was turned to good account in the following manner:—In consequence of arrangements already made, a cellarage for beer was designed, the height of which, from ground level to top of columns is 13ft. 6in. There are besides this cellarage, which occupies about four acres, seven acres more at the goods' stations, devoted to the same purpose. In order to economize the space in the cellarage under the terminus, cast-iron columns about 12in. diameter have been used instead of brick piers. These columns are put upon brick piers capped with stone. The columns are in rectangular lines 14ft. 8in. centres, the spaces between the columns being convenient for the stacking of barrels. There are in all about 700 columns ranged in the manner described, and the large space over which these columns extend is about 700ft. by 240ft. On the top of these columns are placed wrought-iron girders about 2ft. deep, the main girders running across the building and having cross-girders between them, the flooring being made of Mallet's buckled plates, which connect all the main and cross-girders together. The main and cross-girders take their bearing upon the columns, and are consequently all of a uniform span, thus rendering the manufacture of so large a quantity of similar work simple and easy to contractors. It was at once seen by the engineer that these girders would form a most excellent tie to a large arched roof, and accordingly a roof was designed which, when finished, will be the largest single span in the world. Those most nearly approaching to it, though of different construction, are the roofs of the Riding School at Moscow, and that of the Birmingham station roof. The tie in this roof being completely hid there will be no tie-rods, ring posts, or other fittings, which detract considerably from the appearance of a structure of this kind.

Our engravings show elevations, sections, plans, and details of portions of this roof, and we purpose placing further details before our readers next week. The clear span is 240ft., springing from platform level, and the rib will be a four-centred arch, Gothic in character. The height from platform level is 96ft., and the total length of roof 690ft. The principal ribs are composed of plate flanges with diagonal lattice bars connecting them, the total depth of each main rib being 6ft., and are placed at a distance of 29ft. 4in. apart, centre to centre. The ends of these ribs are connected to the transverse girders, as before stated. It should be noticed that provision has been made in the transverse girders not only to take the thrust of the roof, but strength enough has been given to them to carry the weight of the platform, rolling load, and ballast. Between the main principals are placed three intermediate ribs to support the planking, &c., at equal distances of 7ft. 4in., and the whole is braced together by trussed purlins, which occur at equal distances of 17ft. 6in., and correspond to the vertical joints of the arched main ribs. The arched main and intermediate ribs carry the gutters, which form a springing for sash frames, and about 70ft. of each side from centre of the roof is glazed, and the remainder being slated on boarding. The glass is carried by sash bars, which are placed at equal distances apart, and grooved to receive the glass; the sash bars form a ridge-and-furrow roof over the arched rib, and are secured to the purlins by tie bars. As each bar of main principal is divided into lengths of 17ft. 6in., which each contain six diagonals between the flanges, inclined at an angle of 90deg., the disjointed piers are capable of being very easily riveted together in place. For about 30ft. from the springing at each side the main principals are made of plate and angle ironwork instead of lattice work, and is fastened to a plate box which rests on the walls, and is well secured by holding down bolts to anchor plates built in the foundations of the walls. We notice that provision has been made in the two end main ribs for taking the horizontal thrust in the gable end occasioned by the wind. These two principals are placed 14ft. 8in. apart, and are braced together horizontally.

Although the space of this roof is large yet there are several elements of economy in its construction as compared with other roofs of large span. In the first place, the tie is provided for it in the girders which support the flooring. Secondly, there is no wrought work in forging, turning, and screwing, and the fitting of gibs, cottars, and fastening requiring expensive workmanship, but the whole is formed of riveted plate ironwork, such as is employed in ordinary bridges. Thirdly, the side walls are not required to support the weight of the roof, and are therefore made much lighter than would be necessary were the great weight of the roof borne upon the walls. And, fourthly, no provision is required for expansion by temperature, the effect of expansion being a slight elevation in the crown of the roof. Thus the complications of roller frames and adjusting bearings are avoided in this construction.

Upon entering the North London tunnel this portion of the line is carried though a large covered way made for two lines of way; it passes first under the Regent's Canal, where the construction is peculiar. Having to save headway, so as not to approach too near the bed of the canal, cast iron plates are used, well cemented together and bolted, and covered over with concrete and puddle. There are numerous shafts which will ventilate this covered way well. It then passes under the old St. Pancras burial ground, and especial care has been taken to drain the portion well; the arch is well protected by asphalte, and drain pipes are laid alongside the arch on both sides to take off any drainage there may be. It then passes underneath the arching which carries the main line before described, and reaches the Old St. Pancras-road where it intersects the Fleet sewer, this sewer being carried over by a cast-iron pipe supported by wrought-iron girders. After passing the Fleet sewer, it finds its way under the diverted Brewer-street into the St. Pancras station, under which it travels; this branch will connect with the Metropolitan system at King's Cross, in connection with a second Metropolitan line now being made down the Euston-road.

We may mention that Bessemer steel rails are being extensively used on this line, and it is believed that the use of this most excellent material for permanent way may not only prove beneficial and economical to the Midland, but may tend to show to other railways which have not yet adopted it the necessity of doing so, as although the first outlay is considerable, the wear which this steel is capable of bearing will more than repay the difference of cost between iron and steel rails. There are several cab approaches and footway approaches to this station, and every space available seems to have been made good use of. There are shops with handsome frontages, both in the St. Pancras-road and the Brewer-street side, some of which have convenient cellarage. Nothing can be finer than the quality of the work, both in brick and stone. Great care has been taken in preserving the bond of the brick-work, and every piece of cut work is beautifully wrought.

WRECKS IN 1867.

THE annual summary of wrecks and casualties during the past year has been issued by the Statistical Committee of Lloyd's. From a comparison of these with those which occurred in 1866, we have the following results. The cases reported during the past year were 11,424 against 10,587 in the preceding 12 months. The instances of total loss were 2,238, of which 105 were steamers; of constructive loss 323, of which 10 were steamers; of great damage 1,563, of which 132 were steamers; and of minor damage, 3,877, of which 298 were steamers. Forty-four ships and 11 steamers were raised after sinking, and 2,335 ships and 491 steamers among the number reported are classed as not damaged, or results unknown. The proportion of casualties reported in each quarter of the year stands as follows:—First quarter, 3,578; second quarter, 1,927; third quarter, 1,791; and fourth quarter, 4,128. The closing months are usually the most disastrous, but the total for that period of the past year was more serious even than in 1866, the number then having been 3,213. The number of vessels in 1867 abandoned was 455, of which 27 were steamers; the number missing was 100, including 7 steamers; the number burnt or on fire was 138, including 17 steamers; the instances of piracy were 5, all sailing ships, and the cases of collision were 2,062, including 357 steamers. The number of lives ascertained to have been lost was much less than in 1866, the total having been only 1,346 against 2,644—a result attributable, perhaps, partly to increased efficiency of the life-boat service, and partly to the increased care as regards emigrants' ships. The returns relating to lives lost are, it is stated, still most imperfect, the actual number being in excess of that given in the various tables.

A PARLIAMENTARY return prepared by the Metropolitan Board of Works shows that the estimates for the Thames Embankment (north and south) amount to £3,167,515; Mansion House-street, £2,227,837; other approaches, £173,000; total, £5,568,352. The expenditure to the fifth of May, 1868, reached £3,572,013; there was £157,339 available for further expenditure, leaving a further sum of £1,839,000 required.

THE APPLICATION OF TOWN SEWAGE TO GENERAL FARM CROPS.

By THOMAS CARGILL, C.E., B.A.

(Concluded from page 429).

JUDGING from what has already been accomplished in the application of sewage to general farm crops, there is no question but that hitherto grass, and especially Italian rye-grass, has had the lion's share. This is due to several causes which I shall point out when treating of the selection of crops. One of the principal reasons is that, like all grass crops, it grows much quicker than grain crops, and consequently yields a quicker return for the capital expended. Again, there are difficulties and expenses attending the application of sewage to root and cereal crops from which grass land is free. But although we have not so many examples to draw conclusions from as we could wish, yet there is abundant evidence to demonstrate beyond a doubt that sewage can be successfully and profitably applied to the growth of every description of farm crops. A very extensive and careful series of experiments were carried out at Rugby to test the value of the application to oats, and the results were reported by the commissioners to be of the most satisfactory nature, regarded in a pecuniary sense, and to have afforded a remarkably large money return for the proportion of sewage applied. There is, in fact, no place, with the exception of Lodge Farm, at Barking, where sewage has been extensively applied to root and grain crops, but when it is considered that the soil there is of a poor description, the unprecedented success which has attended the application is a better guarantee for what may be accomplished in other places than if we based our expectations upon the produce of a rich and fertile soil. In applying sewage to cereal and root crops a great deal of care and attention is necessary, both with respect to the quantity applied and the time of its application. It cannot be applied so indiscriminately as in the case of grass. If too large a quantity of it be used at one dose, or if the doses be repeated too frequently, the crop will run to straw, and the ear will suffer for it. The experiments at Rugby, to which I have already alluded, confirmed the truth of this remark with respect to oats. When the supply of sewage was confined to about 140 tons per acre, a money value of 5½d. per ton of sewage was returned, but when that quantity was increased to rather more than 500 tons, the value at once fell to 1½d. per ton, as the grain was seriously diminished in consequence. This is what has to be guarded against in growing cereal and root crops under sewage, especially in the case of wheat. There is scarcely any reliable information at present upon the growing of wheat by the application of sewage, but the experiment I am about to mention, although conducted upon a small scale, is of a most encouraging nature, and ought to stimulate others to imitate it upon a scale more extended, and better calculated to do justice to so valuable a crop. About a couple of roods of land belonging to the farm at Barking were ploughed up, irrigated with sewage, and sown with wheat, and at the same time another couple, closely adjoining the former two, were prepared and sown in a similar manner, but were not irrigated with sewage. The crops having been cut, the yield of the sewaged land was found to be exactly one and a-half times that of the land which was not sewaged, and there is very little doubt but that the proportion of the former to the latter would have been much greater had there been a larger area of land experimented upon. This convincing proof of the superiority of sewaged to unsewaged land is more fully borne out in the case of grass when its value is estimated as milk.

Ammonia is known to be a good manure for wheat, but ammonia accompanied with a large quantity of water may not prove a good manure. No amount of ammonia would compensate for the injury that an excessive and unseasonable application of sewage water would do a wheat crop. But in the time of drought sewage becomes exceedingly valuable for grain crops, not only on account of the ammonia it contains, but also for the absolute water in it. This is a fact that is quite lost sight of by the advocates of the dry manure system, who appear to forget that drought is a terrible, and often incurable, cause of barrenness in a soil. Directing our attention to other crops, we find mangold wurzel to have been grown with excellent results under sewage. At Chelmsford, where, as I have already mentioned, circumstances were of an unfavourable character, thirty tons per acre were produced. At Barking, this quantity was nearly doubled, the average return being over fifty tons. Another instance is afforded by this crop of the superiority of sewaged land over that which has not been sewaged. The yield at Barking of mangolds from ground that had been sewaged was just double that grown upon land which had not been sewaged, although it had received per acre twenty tons of cowhouse manure, together with over a quarter of a ton of guano mixed with superphosphates and common salt. This is a crop which deserves the careful consideration of the farmer in laying out land for the application of sewage. Three dressings are sufficient during the growth. Rye-crop has given most satisfactory results, and is a good crop to put down as a change before the re-sowing of rye-grass. Winter-greens also answer very well as a change crop. Besides these crops, others, such as lucerne—a plant of the same genus as clover—beet, flax, celery, and cabbages, have all been grown upon the farm at Barking, and produced returns beyond all expectations. A crop of cabbages sown in August, and watered with sewage every fortnight, yielded a return of £10 per acre, the distance of the plants apart being about 15in. The soil upon which these unexampled results have been obtained is of a poor gravelly description, and the only manure used was the ordinary London sewage, which is probably more diluted than that of any other town, owing to the large drainage area it embraces.

So far as the farmer is concerned he has not much choice in the selection of the best site for the application of sewage, as is the case with local boards. What the farmer has to do is not to look about for the best land—although upon a large estate there may be a good deal of selection in the matter—but to apply the sewage to the land he may happen to possess, whether it be good or bad. He should, of course, exercise his own judgment and practical experience respecting the manner in which the farm is to be divided, and the various crops allotted to it. While, therefore, it may be fairly stated that there is no soil so utterly barren that it cannot be made productive by the application of sewage, yet, at the same time, the situation of it, the nature and levels of the ground, materially affect the financial part of the question. We have seen that at Edinburgh, pure sea sand by sewage irrigation was converted from a state of utter sterility into that of a teeming and prolific soil, and it may, therefore, be reasonably imagined that by a similar course of operations the same results might be obtained in other neighbourhoods. There was for some time a difference of opinion upon this important point, many asserting that certain descriptions of sand could not be rendered fruitful by the use of sewage. Baron Liebig held this opinion, and maintained that all the sewage in the world would never make crops grow upon the Maplin Sands. A short time ago a company was started to irrigate the sands, and as the opinion of so eminent an authority as Baron Liebig was deserving of consideration, it was determined to set the matter at rest, and an experiment was carried out which decided it in the most conclusive manner. As the sewage could not be conveyed to the sands in this early stage of the proceedings it was determined to bring the sands to the sewage. Accordingly, about 3,000 tons were taken up in barges, and spread over an acre of ground, levelled and prepared for its reception. The depth of sand was about 2ft. 6in. During the year four cuttings of grass were obtained from it, one crop yielding twenty tons per acre. Smaller plots of the same made ground were equally productive with respect to mangold and other crops.

Admitting the practicability of applying sewage to every possible description of soil, with nearly equally good results, it is still evident that the management must be varied to suit the particular nature of it. A much larger quantity of sewage may be applied in the case of light, porous, gravelly soils than upon stiff clays, particularly during the first year of the application. It would appear that gravelly soils require a certain time to become thoroughly saturated with the sewage, and absorb it greedily while the operation is in progress. This fact is corroborated by the experience acquired at Barking. When the sewage was first brought on to the land an enormous quantity of it went to waste in the carriers, which, being cut in the gravelly soil, absorbed it with extreme rapidity. The settling tank was, in consequence, not used for a long time, in order to allow the sewage to carry as much mud along with it as possible, and, by depositing it in the carriers, render them ultimately water-tight, which appears now to be the case. The practical lesson to be learnt from this is that if the supply of sewage was very limited, and the ground of an exceedingly porous nature, it might be worth while to make the carriers water-tight by puddling them, or by other means. During the winter time, when the crops are stationary, stiff soils probably retain the fertilizing constituents of the sewage better than the lighter descriptions of land. With all crops of a rapid growth, as grass, which quickly assimilate the elements they require from the soil, the character of it is not of much consequence. Three different descriptions of soil are sewaged at Croydon with much success. One is a sandy, gravelly soil; another gravelly, mixed with loam; and the other a stiff, clayey one.

The question of the proportion of land to be sewaged by a given population, however interesting it may be to local boards, does not much concern the farmer, but it may be generally accepted as a good practical estimate that one acre of ground will require the sewage of 100 persons to yield annually forty tons of grass. The application annually of 5,000 tons of sewage per acre is calculated to give a certain average return of thirty tons of grass. This quantity is sufficient to supply all the potash needed by the plant, without taking any from the soil, but if the latter be rich in potash a less amount of sewage will suffice. It is impossible to state, with respect to grass crops, the exact limit at which the application of sewage ceases to give a productive return. Between 5,000 aud 6,000 tons is the most profitable quantity under all circumstances to apply annually per acre, but at Edinburgh over 8,000 tons is the usual allowance. One point is very certain, that is, that after a given quantity of sewage has been applied the applicatipn of more is not attended with a proportionate increase in the result.

There are three principal methods of actually applying the sewage to the land, known respectively as the hose and jet system, the method of sub-irrigation, and the method of surface channels. There is a fourth plan of irrigation by total submersion, or literally laying the land for a certain time under water. This is practised in Piedmont and other continental districts, but as it is not applicable as a rule to sewage, I need not discuss it. In describing these different methods the sewage is supposed to be brought upon the farm ready to be distributed. The means of conveying it, whether by pumping or by gravitation, are connected with questions of engineering works and estimates which would be out of place for me now to allude to. To commence with the hose and jet system. Small pipes are first laid down, through which the sewage must be forced. To accomplish this it is necessary to have a certain head of water, not less than about 10ft., which entails a great waste of power, consumed in not only overcoming the friction of the pipes, but also in imparting the requisite momentum to the jet. By this system the sewage must always be raised a few feet higher than the level of the land, a disadvantage not occurring in either of the other two methods. The hose and jet plan can be applied to land of any form of surface without the necessity of any especial preparation or laying out in beds. But as a balance against this advantage must be set the cost of the piping, hydrants, and other appliances, which will exceed that of the preparation of the ground for the application of the other principle. On the farms of Alderman Mechi, and Mr. Nielson, the hose and jet system has had a partial success, but then it must be remembered that town sewage is not used, but liquid manure, which is a much stronger and more concentrated fertilizer than the former. Moreover, at these two places, ordinary farm manuring is carried on as well. The dragging of a long length of hose among crops is a troublesome and tedious operation, to call it nothing worse, and grass could not well be sewaged in this manner, except during the early stages of its growth, which would not suffice to produce the splendid annual crops which have been obtained at Edinburgh and Barking. In the best seasons at Edinburgh so much as 80 tons of meadow grass have been got off one acre, which was sold for £35. The utility of this method is very much impaired by the restrictions imposed upon it with respect of time, since one of the most important features of the application of sewage is that it should be able to be applied at any and at all times, in the day-time as well as the night-time, and at any stage of the growth of the crop. Objections have been taken to the fact that the distributing of the sewage over the crop, instead of applying it direct to the roots is wrong in principle, and that a deposit is thereby left upon the leaves and those portions of the plant above ground, exceedingly injurious to its growth.

At Rugby, Alnwick, Watford, and other locali-

Digitized by Google

ties, the hose and jet method has totally failed. Mr. Rawlinson, the well-known commissioner of sewers, has stated that it would cost more to distribute 500 tons of sewage per acre by means of this method than to apply 5,000 tons by the system of surface channels.

The second method, namely, that of sub-irrigation, has not been practically tried except on a very small scale, as it is not only a very expensive plan, but also promises little hope of being successful. It consists in laying down below the top soil porous or perforated pipes, the ends of which can be closed when required, and the sewage forced through the pipes into the soil. Now it will be at once apparent that as the pipes must be laid at such a depth as to be out of the reach of the plough and other tillage implements, the plants scarcely derive the full benefit that they ought to do from the sewage, more particularly as it is distributed very slowly, and is in some danger of complete stagnation in the interior of the pipes, owing to the stopping up of the holes by solid deposits. It is not by any means clearly established how these underground pipes act, or whether a portion of the sewage does not drain away from them instead of rising to the level of the roots of the plant, in which case the waste might be very great. Under certain conditions the pipes used for ordinary subsoil drainage may be made to answer the purpose of this system, by merely stopping up their outlets during the season of irrigation. This plan has been adopted in Switzerland and a few other places.

Of the three methods, that of surface channels is the only one which has been attended with undoubted success, and as it is the one I should recommend to be adopted I shall describe it more in detail. It is the only principle applicable upon a large scale to sewage irrigation, and fitted to contend with the difficulties that have to be encountered. It may be subdivided into three distinct kinds, namely, the catch-water, or catch-work plan, the pane and gutter, and the ridge and furrow. All of these are distinguished by their simplicity and efficiency, and the adoption of one or other depends upon the physical features of the ground. The catch-work plan is best adapted in the case of steep or even hilly grounds, and is the cheapest mode of applying sewage. The ground having been first carefully levelled over, or contoured, as it is technically termed, gutters or carriers are cut along the contour lines at convenient distances from the top to the bottom of the field. These carriers are cut transversely to the slope of the ground, and are perfectly level in the direction of their length. The sewage being brought into the uppermost carrier fills it, and then flows over the edges on to the land into the lower carrier, and so on until it reaches the lowest one, which conveys it away to the outlet.

It is not absolutely necessary for the sewage to be brought first into the top carrier; it can be brought into any one, as it is sometimes advantageous to give a portion of a field an extra dose. According to the slope of the ground, so must the distance between the carriers be regulated; about 35ft. may be considered an average distance. As to the slope itself, 1 in 12 will be found a good limit, although 1 in 4 or 5 has not been considered too steep. When the ground, however, has a slope of this steepness, there is danger of the sewage passing off so rapidly as not to benefit the land to the proper degree. The cost of preparing the ground and cutting the carriers for the application of sewage upon this principle will not exceed about £2 per acre.

When the ground has a gentle inclination the pane and gutter system is generally adopted, and the ground is prepared in the following manner. Main carriers are cut right across the field, or in the direction of its least fall, and another series of smaller gutters are cut radiating from them in the direction of the greatest slope of the ground. The land between these secondary or distributing carriers is laid out perfectly level, and stops made of oak or elm boards placed at intervals across them. In addition to the distributing carriers, discharging gutters are cut parallel to them, and the manner in which they act is as follows:—The sewage flows from the main into the secondary carriers, where, by the proper use of the stops, it is dammed back, and made to flow over the land until it reaches the discharging gutter which conveys it away. This principle has been extensively employed with the greatest success at Croydon and Norwood, its management being both simple and satisfactory. The cost of forming the ground and cutting the carriers for the pane and gutter system at Craigentenny was about £12 10s. per acre, which is a high price, and the annual expense of maintaining the fields in working order is a little over £3.

The third method to be described is that known as the ridge and furrow, or bed method, which is applicable to land perfectly level, and necessitates a good deal of preliminary formation of the ground. As the name signifies, a ridge is formed by raising the earth, which is taken from the slide slopes running down to the furrows, which lie in the hollow between two adjacent sides. The operation can hardly be called excavating: it is rather a transference of the soil from one spot to another. Carriers are constructed in the artificially-formed ridges and furrows, and the sewage, after entering and filling those on the ridges, flows over the side slopes into the drains in the furrows, and runs into the nearest watercourse. The sides of the slopes are the panes, as they are sometimes called (which is a badly chosen term, as it confuses this system with the pane and gutter), are carefully levelled and dressed to an inclination of about 1 in 120, and the ridges may be placed at any average distance apart of from 25ft. to 75ft., according to the crop put into the ground. It is difficult to estimate what the cost of forming the ground upon this system would come to, without knowing the particulars of each case. £5 per acre may be stated as the lowest, and £20 as the highest price. A large area of land at Barking has been laid out upon this method for the growing of grain crops during the present year.

All these subdivisions of the "surface channels" principle possess the great advantage of being able to deliver the sewage upon the land at all times, and during all stages of the growth of the crop, even up to the time of cutting it, should it be grass. Any stagnation of the sewage upon the land must be prevented by levelling all irregularities, and filling up all holes and hollows, so as to maintain the flow as uniform as possible. In artificially forming the ground the best soil should be kept on the surface. The general principles that ought to guide a farmer in the laying out of his farm for the application of town sewage are not difficult to arrive at, although they must always be modified by the peculiar circumstances of the locality, the nature of the soil, the shape of the ground, and a number of minor points belonging to every individual instance. A certain amount of grass, whether meadow or rye-grass, must be grown, in order to dispose of the sewage at all times, and to form an outlet, as it were, for it, whenever the condition of the other crops does not allow it to be applied to them. A farm composed entirely of arable land would be unsuited to the application of sewage, provided it were required to dispose of the sewage at all times, which would be generally the case. Green crops are the only ones which can stand, and, in fact, benefit, by the application of excessive quantities of sewage. Other crops cannot be stimulated or forced to the same extent, and are only injured by doses of sewage too often repeated. When sewage farming is better understood, and reduced to scientific principles, it will be found more economical to devote a much larger area of land to the production of root and cereal crops than is done at present. The truth is, that there is a mania just now for growing grass, particularly Italian rye-grass, which is no doubt the great sewage crop. This is partly owing to the fact that at Croydon and the few other places where sewage is profitably applied, grass is the best paying crop, a ready market being found for it, owing to the situation. Milk is one of the most essential articles of food, and brings a high price in every large town. Consequently the crop which contributes most to its production is certain to find a ready sale, whether it be cut for garden or grazed off the land. At the same time it would be a most short-sighted policy to imagine that the application of sewage is to begin and end with green crops. In fact, the true value of it will never be appreciated until it is extensively applied to roots and cereals. At present it is wasted; there is too much of it to be had for nothing; then, it will be properly economized and estimated as it ought to be. From the facts I have laid before you it is manifest that the future system of sewage farming will be a combined one, and will consist in so proportioning the relative amounts of grass and arable land as to dispose of the sewage in the most effectual manner. The farmer will also be relieved from a great difficulty. Although he will have a choice, he will not be able to say, as at present, "I cannot grow such and such a crop, the ground is too poor;" for the real value of sewage is that by its means the poorer soils are raised to an equality with the richer, and made to be equally productive. Bearing in mind that grass will stand a very large quantity of sewage, there is not the slightest fear of not being able to dispose of it, provided a judicious selection be made in the choice of the crops grown. While any crops may be grown to great perfection, yet the most profitable ones will, of course, depend upon local circumstances, of which the farmer himself is the best judge. It may be stated that while sewage is a valuable fertilizer for all descriptions of soil, it is a perfect regenerator for the poorer kinds. It may be expedient in the one case, but it is absolutely essential in the other. An objection has been taken to the application of sewage to rye-grass, that it caused the crop to be very rank. This is not the fault of the sewage, but of the farmer. If rye-grass be cut immediately before it begins to form seed, it will never be either coarse or rank. It should be ploughed up every second year, a root crop taken out of the ground, and then it may be resown. One acre of Italian rye-grass irrigated with 5,000 tons of sewage will yield 1,000 gallons of milk per annum, equal to a money value of over £33. There is an advantage in applying sewage to cereal crops which is not always taken account of, more particularly if the land be tolerably fertile. After applying the sewage in large doses for two or three years on grass lands, intermediate grain crops may be grown in great perfection from the manure or residue of sewage constituents left in the land. Clayey soils in particular possess a remarkable power of retaining or storing up food for plants. Were rye-grass to be cut every two years, or even every eighteen months, it would allow of a very judicious and profitable combination of sewage farming, as intermediate crops of mangolds, potatoes, and cabbages could be got out of the land with great success. Viewing the question of the application of sewage to crops upon a broad basis, there is but little doubt that through its means land which is now impoverished and exhausted, or rendered barren by natural or artificial causes, will be restored to its original fertility. Not by simply applying sewage to grass crops, or by continuing the application for two or three years, but by a regular scientific, systematic course of sewage farming and sewage engineering for the future Can it be expected that a period of a few years can repay the evils which it has taken ages to create, or that a brief application of the remedy can cure a disease that has been aggravated by the lapse of centuries? Most fortunately at the present time, by one of those coincidences which invariably attend cause and effect, land is wanted for the application of sewage, and sewage is needed—urgently needed—by the land. It is from the union of the two that national wealth and prosperity will result, but we shall never carry out the union in its integrity, never avail ourselves to the full degree of the advantages at our disposal, or do justice to the resources in our power, until sewage pipes are laid on to the land for the use of the farmer and agriculturist in the same manner as water and gas pipes are laid on for the supply of our cities and towns.

MANCHESTER BOILER ASSOCIATION.

THE last ordinary monthly meeting of the Executive Committee of this association was held in Manchester on Tuesday, May 26, 1868, Charles F. Beyer, Esq., C.E., in the chair, when Mr. L. E. Fletcher, chief engineer, presented his report, of which the following is an abstract:—"During the past month 276 visits of inspection have been made, and 698 boilers examined, 532 externally, 11 internally, 6 in the flues, and 149 entirely; while, in addition, 3 have been tested by hydraulic pressure. In these boilers 102 defects have been discovered, 4 of them being dangerous, thus:—Furnaces out of shape, 4; fractures, 15—2 dangerous; blistered plates, 5; internal corrosion, 27; external ditto, 6; internal grooving, 8; water gauges out of order, 5; blow-out apparatus ditto, 8; fusible plugs ditto, 1; safety valves ditto, 1; pressure gauges ditto, 14—2 dangerous; boilers without pressure gauges, 2; without feed back pressure valves, 5; cases of deficiency of water, 1." Mr. Fletcher presents a long list of explosions, six having occurred during the past month, resulting in the death of six persons and injury to seven others. In addition to these, reference is made to an explosion which ranks as No. 11, and occurred during April, but particulars of which were not received in time to be included in the last report. Not one of the exploded boilers was under the inspection of this Association. No. 11 explosion, by which one person was injured, occurred at a paper mill, at a quarter before two o'clock, on the after-

Digitized by Google

noon of Wednesday, April 15. The boiler was No. 3 in a series of four, set side by side, all of them being internally-fired, and of plain single-flued Cornish construction, while the one in question was 15ft. long, by 4ft. 7in. in diameter in the shell, and 2ft. 8in. in the furnace tube, the thickness of the plates in the latter being a quarter of an inch, and the steam pressure 60lb. The boiler failed through collapse of the furnace tube, the crown of which came down and rent near the firebridge, when the rush of steam and water blew up the brick flue at the back of the boiler and severely scalded one of the workmen, but did not disturb the boiler from its seat.

The cause of the collapse has been attributed to shortness of water through the neglect of the attendant. As the furnace tube was removed at the time of examination, Mr. Fletcher is not prepared to offer a positive opinion on this point, but he was assured at the works that the glass gauge showed an ample supply of water at the time, while it may be pointed out that the furnace tube being made of plates only a quarter of an inch thick was quite unfit for a pressure of 60lb. on the square inch, constructed as this one was without any strengthening rings or other appliances, while, further, there was no feed back pressure valve, so that there was nothing to prevent the water's being vomited from one boiler to the other, which would have laid bare the furnace crowns in a few minutes. Whether, therefore, the attendant had been neglectful or not, the furnace tube was weak, and the complement of fittings defective, and, however convenient it may be to throw the blame on the attendant, the boiler makers cannot be exonerated in the present instance, and the explosion affords an additional illustration of the necessity of competent periodical inspection to check the construction and equipment of boilers, as well as their condition.

The following explosions occurred from April 25, 1868, to May 22, 1868, inclusive:—April 30, plain cylindrical, egg-ended, externally-fired—1 killed, 3 injured; May 1, single flue, or Cornish, internally-fired—1 killed; May 9, single-flue, or Cornish, internally-fired; May 11, plain cylindrical, camber-ended, externally-fired—1 killed, 1 injured; May 11, multitubular marine, internally-fired—1 killed; May 12, plain cylindrical, camber-ended, externally-fired—2 killed, 3 injured; total—6 killed, 7 injured.

ON SOME EFFECTS OF THE HEAT OF THE OXY-HYDROGEN FLAME.*

By Mr. William Odling, F.R.S.

CHEMICAL changes, whether of combination or decomposition, result in the production of new bodies which, under the conditions of the change, have for the most part a greater stability than the original bodies. One evidence of this greater stability is afforded by the development of a quantity of heat—the heat of chemical action—from the produced bodies having a smaller potential heat than the original ones. It results, both from reason and experiment, that in order to undo or reverse any definite chemical action, just so much heat must be directly or indirectly expended as was evolved by the original action. For the same quantity of heat evolved, the resulting temperature varies with the mass and kind of matter heated, and with the rapid or gradual evolution of the heat. When the evolution of heat is instantaneous, the resulting temperature may be calculated from the quantity of heat evolved, and the mass and specific heat, &c., of the matter heated. By a unit of heat is meant the quantity of heat necessary to raise the temperature of one kilogramme of water one degree Centigrade, or more accurately from 0deg. to 1deg.

Every 18 grammes of water is a combination of two 1-gramme proportions of hydrogen H, with one 16-gramme proportion of oxygen O; and, by the combination of 2 grammes of hydrogen with 16 grammes of oxygen, there are developed 68 units of heat. Of these 68 units of heat, however, little more than 57 units are really due to the chemical action—nearly 11 units of heat being evolved by the contraction of the original mixed gas into two-thirds its volume of steam, and by the further condensation of the resulting steam into 18 cubic centimetres of water. While the quantity of heat evolved by the combination of a given quantity of oxygen and hydrogen is invariable, the intensity of the heat may vary from a scarcely recognisable rise of temperature up to the highest temperature of the oxy-hydrogen blow-pipe flame, capable of fusing platinum and silica. A most remarkable effect of the intense temperature resulting from the combination of oxygen and hydrogen into water, is the partial decomposition of water into oxygen and hydrogen, discovered by Mr. Grove in 1846. At this high temperature, hydrochloric acid and carbonic anhydride gases also undergo partial decomposition into hydrogen and chlorine, and into carbonous oxide and oxygen respectively. Upon what do these singular decompositions by heat, of bodies formed with great evolution of heat, depend; or with what class of chemical phenomena may they be associated?

Under certain familiar conditions, chemical action seemingly takes place to its utmost possible extent in a single direction only, with production of a maximum amount of the substance that is formed with maximum evolution of heat. For example, taking atomic proportions in grammes, the heat of formation of chloride of zinc, $ZnCl_2$, is 101 units, and the heat of formation of chloride of copper, $CuCl_2$, is 60·5 units. Hence, with chlorine in solution and excess of both copper and zinc, there is finally produced the maximum possible amount of chloride of zinc and no chloride of copper. Again, an addition of sufficient zinc to solution of chloride of copper, there is complete combination of chlorine with zinc and complete separation of chlorine from copper, *i.e.*, complete burning of the one metal and complete unburning of the other.

But under simpler though less familiar conditions, chemical action habitually takes place in more than one direction simultaneously, with production of correlative products in varying proportions. Thus, with hydrogen and excess of both chlorine and oxygen, although the heat of formation of oxide of hydrogen H_2O is 57 units, and the heat of formation of chloride of hydrogen, 2 HCl, is only 47·5 units, yet, in this case, the hydrogen does not combine with the oxygen to the exclusion of the chlorine, but divides itself between the oxygen and the chlorine in proportions which vary with the conditions of the experiment. In accordance with this result it is found that, at the same red heat, excess of chlorine will effect the partial decomposition of water with extrusion of oxygen; and, conversely, that excess of oxygen will effect the partial decomposition of hydrochloric acid with extrusion of chlorine. So that, beginning with the two chemical substances, water and chlorine, or beginning with the two chemical substances, hydrochloric and oxygen, or beginning with the three chemical substances, hydrogen, chlorine, and oxygen, there exist, at a full red heat, the four chemical substances, water, hydrochloric acid, chlorine, and oxygen; the proportions of the four substances depending certainly upon the relative quantities present of the elements concerned, and most probably also upon the temperature of the experiment. Similarly, beginning with the one chemical substance water (Grove), or beginning with the two chemical substances, oxygen and hydrogen (Bunsen), there always exist, at a sufficiently high temperature, the three chemical substances, water, oxygen, and hydrogen. Although, by exposure to a red heat, the electrolytic mixture of oxygen and hydrogen gases becomes completely combined, or transformed into water, yet, as recently shown by Bunsen, at the high temperature of 2,024deg., only one-half, and at the still higher temperature of 2,844deg., only one-third of the mixture undergoes combination, the other one-half or two-thirds remaining in the state of mixed gas.

Chemists are acquainted with many reciprocal actions comparable with those of chlorine upon water, and of oxygen upon hydrochloric acid, the most familiar instance being probably the decomposition of ignited oxide of iron by hydrogen with extrusion of iron, and the converse decomposition of oxide of hydrogen by ignited iron with extrusion of hydrogen. Similarly, sodium will decompose the oxides of carbon, while carbon will decompose oxide of sodium; and just as a sufficient excess of chlorine may be made to effect the almost complete decomposition of a given quantity of water, so may a sufficient excess of carbon (or carbonous oxide) be made to effect the almost complete decomposition of a given quantity of sodium-oxide or zinc-oxide, as in the ordinary processes for obtaining the two metals; notwithstanding that, for an equal consumption of oxygen, the respective combination heats of sodium and zinc exceed by far the combination heat of carbon or carbonous oxide. Again, although the combination heat of oxygen and carbonous oxide is 68 units, while that of oxygen and hydrogen is only 57 units, yet, as was shown by Bunsen many years ago, upon exploding a mixture of oxygen with a joint excess of carbonous oxide and hydrogen, the oxygen does not attach itself exclusively to the carbonous oxide, but divides itself between the carbonous oxide and hydrogen in a ratio determined by their relative proportions.

* Read before the Royal Institution of Great Britain.

STEAM FIRE ENGINES.

THE corporation of the borough of Wigan have recently purchased of Messrs. Merryweather and Sons, of London, the large-size double cylinder steam fire engine "L'Empereur," one of the engines which the firm exhibited at the Paris Exhibition of last year, where, it will be remembered, the first prize, and only gold medal, was awarded to them. The trials made with this engine at Wigan have shown that the engine is quite capable of projecting and maintaining a stream 1¾in. diameter to a height of over 200ft., and of raising 100lb. pressure of steam from cold water in from ten to eleven minutes. By way of experiment, jets of 2in., 2¼in., 2½in., also four of 1in. and eight of ¾in. were delivered by this powerful machine; whilst doing this great amount of work the engine remained perfectly steady. It has two steam cylinders, each 8¾in. diameter, and two horizontal double-acting pumps, each 7in. diameter, with 24in. stroke of steam and water pistons. Engines of similar size have been supplied by these makers to five of our Royal dockyards.

Correspondence.

MAGNETIC PHENOMENON.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—If your correspondent, "A. de B.," of Delft, will duly reflect on the experiment he has described at page 435 in your journal, June 5, he will see there is nothing remarkable in the north pole of the magnet attracting the suspended needle at C. It should do so. He has forgotten that in magnetizing the point of the needle (which was thrust through the cork) with the north pole of the magnet, he communicated to it a south polarity. The south pole of the magnet of course communicated a north polarity to the point of the suspended needle, the lower end of which would of necessity be a south pole, and, therefore, attracted by the north pole of the magnet, when presented to it. As regards the oscillations of the needle, if he will place the bottle on a support free from tremor, the suspended needle will soon attain a state of rest.—I am, Sir, yours, &c.,

J. B. DANCER.

Manchester, June 9.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Meetings for the Week.

MON. — Royal United Service Institution. — Major Palliser, unattached, late 18th Hussars, on "The Construction of Heavy Rifled Ordnance," at 8.30 p.m.

THURS. — Royal Institution.—Sir J. Lubbock on "Savages," at 3 p.m.

FRI.—Royal United Service Institution.—Colonel W. F. D. Jervois, C.B., R.E., Deputy-Director of Works for Fortifications, on "Coast Defences, and Application of Iron to Fortification," at 3 p.m.

SAT.—Royal Institution.—Sir J. Lubbock on "Savages," at 3 p.m.

DURING the past week 34 wrecks were reported, making for the present year a total of 989.

Digitized by Google

Naval, Military, and Gunnery Items.

A PANORAMA of the Isthmus of Suez, representing the works executed by the company of M. F. de Lesseps, has been brought out in Paris. Before the public were admitted, M. de Lesseps invited the members of the press to the panorama, and intimated to them that "it was but the beginning of the voyage which the company was going to organise next year."

THE "Monster Tower Drums" were originally manufactured for the Great Handel Festival, held in Westminster Abbey, A.D. 1784. They were called "Tower" drums, owing to the fact that the heads were made from the skins of the celebrated lions exhibited at the Tower of London about that period—a circumstance now almost forgotten.

THE Duke of Northumberland will distribute the prizes to the cadets, on board the "Worcester" training-ship lying off Erith on the 23rd inst. The Queen's prizes, which in future will be annual, will this year be given for the first time. These consist of a gold medal, to encourage the boys to acquire and maintain the qualities which will make the finest sailor, and a binocular glass, with a suitable inscription, and a sum of £35 to the boy who shall have obtained the naval cadetship given by the Admiralty.

ANTWERP is not only the principal port of Belgium, but also the emporium, for the greater part of Germany. Since the peace of 1815, the trade of Antwerp has continually increased. In 1824, the number of ships that arrived at this port was 681; in 1825 the arrivals amounted to 800; in 1836 to 1,426; in 1861 to 2,786; and in 1866, the number of arrivals amounted to not less than 3,085 ships, of the aggregate tonnage of 885,052, and the departures to 3,031 ships, of 885,052 tons.

ARRANGEMENTS are in progress with the view of placing several heavy Palliser guns on the forts at Pembroke Dock and Milford Haven. The first five have been shipped at Woolwich, and are expected to arrive in the course of a few days, when they will be removed and placed in position, at Popton on fortress. The next five will be placed at Hubberston, and the other forts will receive their complement in due time. These formidable pieces of artillery are of very large calibre, and weigh about 12½ tons each.

THE "Pallas" has been placed in dock at Portsmouth, to cleanse her hull below the water-line, preparatory to making her ordered experimental trials at sea. Fifty tons of coals will be taken out of her coal bunkers, and 50 tons of ballast fixed on her upper deck, the purpose in this change in the disposition of her weights being to raise, so far as these means will effect it, the centre of gravity of the hull, and ascertain in the forthcoming trials its effect upon her tendency to roll at sea.

CAPTAIN ROBERTSON, R.N., of the Board of Trade, has just completed his annual inspection of the Volunteer Life Brigades, on the north-eastern coast, established for the rescue of shipwrecked seamen. The corps are composed of young men of all classes of the community, and have been found in a high state of efficiency. The Tynemouth, South Shields, and Cullercoats Life Brigades have club-houses admirably fitted up, and complete arrangements are made for the reception and restoration of shipwrecked men immediately after they are landed from wrecks. The movement was commenced at Tynemouth a few years ago, and is gradually extending to other large seaports and fishing villages. It has the hearty support and co-operation of the Board of Trade.

ON Tuesday the River Wear Commissioners opened the new docks at Sunderland of eleven acres area. The long depression in the shipping trade has so reduced the funds at the disposal of the commissioners that economy necessitated the avoidance of any costly ceremony. Flags were hoisted at the masts of nearly all the ships in port, and thousands of the inhabitants assembled to witness the commissioners run a fine steamer of 2,000 tons burden, and other large vessels, into the dock shortly after low water, showing what deep-water accommodation would be afforded at high water.

AT a recent meeting of the Cork Harbour Board a communication was read from the Board of Trade containing a proposal with reference to the blasting of Daunt's Rock, providing that whatever sum of money might be paid out of the Mercantile Marine Board for the purpose, an equivalent should be paid by a special toll levied off the trade of Cork, so as to indemnify the Mercantile Marine Fund. The board unanimously rejected the proposal on the ground that it was an imperial rather than a local measure, and that the trade of Cork had no right to be called on to contribute at all.

ADVICES from San Francisco state that the monthly service of the Pacific Mail Steamship Company to Japan and China commenced on June 3. The "Great Republic," which left San Francisco on March 4, when within about 2,000 miles of Yokohama, became partially disabled, and proceeded under sail and one wheel to that port. The remaining part of the voyage to Hong Kong and back to San Francisco was completed by the company's steamer "New York," which was then at Yokohama, and the round, it is said, exceeded by only two days the contract time.

Miscellanea.

A MONUMENT from the hand of the sculptor Molin is to be erected at Stockholm to the memory of King Charles XII. The inauguration is to take place on November 30 next, the 150th anniversary of the monarch's death.

THE Parliamentary session commenced on the 19th of November, and the result up to the present period has been 30 public and 31 local Acts, making 61 in nearly seven months.

THE Bath and West of England Agricultural Society, which is now amalgamated with the Southern Counties Adult Education Association, has decided to hold its exhibition for 1869 at Southampton, subject to the site being approved of by the council, and other conditions.

FORTY-FIVE miles of steel rails are laid on the Lehigh and Susquehanna Railway, connected with the North Pennsylvania at Bethlehem. There was not one broken rail caused by the trains during the past winter.

ADVICES in relation to the volcanic eruption in the Sandwich Islands state that at Kakuka, on April 7, the lava again burst forth through a fissure nearly three miles long, and run, in a few hours, twelve miles, from a height of 3,800ft. to the sea, forming a solid projection half a mile in length.

IN Paris, for some days past, a number of cabs have been seen with the new kilometrical meter for measuring the distance traversed. The apparatus is fixed to the seat, at the left of the coachman; and resembles a small timepiece. The comparison is so much the more exact that near the traveller is a dial which marks the hour.

AN official statement relative to the cost of the Thames Embankment has been issued. The receipts to May 5 last amounted to £3,729,352, and the payments to £3,572,013, and the sum required to complete the work is £1,839,000. The original estimate was £4,935,320, but (according to the foregoing figures) the present estimated cost will be £5,568,353.

THE amount of capital accumulated in the Post Office Savings Banks at the close of 1867 was £9,230,229; at the close of 1866 the corresponding total was £7,719,981; at the close of 1865, £6,161,488; at the close of 1864, £4,687,893; and at the close of 1863, £3,131,535. Thus, in four years the aggregate balance at the credit of depositors in the Post Office Savings Banks increased to the extent of £6,098,694.

AT the last meeting of the Royal Geographical Society the following gentlemen were elected Fellows of the society:—W. A. Bell, Esq.; A. T. Bowser, Esq.; W. Clark, Esq.; Hon. G. S. Gough; T. C. Graham, Esq.; Sir George P. Lee, Bart.; his Excellency Lieutenant-General Sir Robert Napier, G.C.B.; G. F. Plumberg, Esq.; C. J. Smith, Esq.; Captain the Hon. W. J. Ward, R.N.; M. Williams, Esq.

DURING the year 1866 there were produced from mines in the United Kingdom 101,630,544 tons of coals, valued at the place of production at £25,407,635; 4,523,897 tons of pig iron, valued at £11,309,742; 11,153 tons of fine copper, valued at £1,019,168; 67,390 tons of metallic lead, valued at £1,381,509; 9,990 tons of white tin, valued at £885,368; 3,192 tons of zinc, valued at £69,916; 636,188 tons of silver from lead, valued at £174,951, and other metals, valued at £95,000, so that the total value of coal and metals taken from British mines in the year above referred to was £40,345,945, including 743oz. of gold, valued at £2,656.

THE exhibition of rhododendrons, azaleas, &c., generally called "American plants," which opened in the Royal Botanic Gardens, Regent's-park, last Monday, has now attained its maximum beauty. The extraordinarily fine spring has been so much in favour of this as well as nearly all classes of plants that the display is considered finer than on any former year. Much also is due to the energy of Mr. John Waterer, the cultivator of the plants, for the great variety of colour of the flowers, which ranges from pure white and delicate rose to deep purple and vivid crimson. A very curious effect is produced by the large mass of bright colour within the marquee, which is filled with a glow of peculiar light.

THE amount of Customs revenue collected at Glasgow in May was £74,818, as compared with £90,009 in May, 1867, and £68,994 in May, 1866. At Greenock, Customs revenue was collected in May to the extent of £105,708, as compared with £101,068 in May, 1867, and £132,322 in May, 1866. The imports of sugar into the Clyde in the first five months of this year amounted to 66,389 tons, against 78,587 tons in the corresponding period of 1867; the deliveries for home consumption in the Clyde during the last five months amounted to 69,613 tons, against 70,788 tons in the corresponding period of 1867. The stock in bond in the Clyde at the close of May was 12,757 tons, against 26,785 tons the close of May, 1867.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending June 6, was 6,842; total number since the opening of the museum, free daily (May 12, 1858), 1,309,653.

THERE are two specimens of the mocking bird now in England. They are to be seen in the aviary at the Crystal Palace, near the crystal fountain. They are in full song, and warble the notes of the thrush, blackbird, nightingale, mock the railway whistle, the sawing of wood, and whistle some English songs.

THE visitors to the South Kensington Museum during the week ending June 6, were—On Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m.; on Wednesday, Thursday, and Friday (free), from 10 a.m. till 6 p.m., 25,152, National Portrait Exhibition, by payment, 2,439; total—27,591. Average of corresponding week in former years, 20,948; total from the opening of the Museum—7,437,548.

THE sale of fungi in Milan is under great restriction, and is only allowed in the public markets, so as to be under the immediate eye of the market inspectors. The sale of all fungi prejudicial to health, as also of those but little known, even if not poisonous, is strictly prohibited. The following, says the "Society of Arts' Journal," are the only varieties of fungi which are permitted to be sold in the Milanese markets:—

Names in Milanese Dialect.	Italian names.	Botanical names.
Funsg ferree	...Fungo porcino...	Boletus edulis.
Funsg cocch	...Uovolo	...Agaricus cæsareus.
Spongignœura...	Spugnuola	...Phallus esculentus.
Trifola	...Tartufo	...Lycoperdon tuber.

Any infringement of these regulations is punished by fines and imprisonment.

AT the earthenware manufactory of Messrs. Powell and Bishop, Hanley, Staffordshire, a fortnight ago, it was noticed that the walls of a portion of the building, called the "saggar" house, were gradually falling out of the perpendicular, but several days elapsed before it was found to be due to a seam of coal, technically known as a "smut," which crops up under that part of the building, having become ignited by one of the flues of the "saggar" house, and the fire had in all probability been smouldering for a considerable time. A mining engineer was consulted, and he advised that a shaft six yards deep should be sunk near the seam, and the fire cut off by driving lateral galleries.

TWO volumes have been issued among the Parliamentary papers, an instalment of a series of six volumes of reports on the Paris Universal Exhibition of 1867. One volume will contain the general report, the statistical tables; four volumes will be occupied by reports on the various classes; and the sixth volume is devoted to returns relating to the new order of reward for success in the development of a spirit of harmony among those co-operating in the same work, and in making provision for the material moral and intellectual well-being of the workmen. The reports on the various classes were prepared for the Science and Art Department in accordance with the direction of the Committee of Council on Education. The two volumes first issued are Vol. II. and Vol. VI.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3319, 3321, 3343, 3348, 3350
BUILDINGS AND BUILDING MATERIALS—3377
CHEMISTRY AND PHOTOGRAPHY—3358, 3360, 3389
CULTIVATION, OF THE SOIL, including agricultural implements and machines—None.
ELECTRICAL APPARATUS—3317, 3346, 3390
FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—3329, 3338, 3347, 3351, 3357, 3371, 3372 3384, 3385
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—3323, 3359
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—3303, 3383
GENERAL MACHINERY—3310, 3312, 3314, 3315, 3316, 3322, 3330, 3332, 3337, 3354, 3366, 3367, 3369, 3373, 3375, 3381, 3386, 3387, 3388
LIGHTING, HEATING, AND VENTILATING—3318, 3353, 3361 3376
METALS, including apparatus for their manufacture—3340, 3352, 3355, 3360
MISCELLANEOUS—3311, 3313, 3326, 3327, 3328, 3335, 3336, 3339, 3341, 3342, 3344, 3349, 3364, 3370, 3374, 3378, 3380, 3382

STEAM ENGINES—3309, 3320, 3334, 3379
WARFARE—3308, 3324, 3345

3309 J. G. TONGUE. *Improvements in gibs applicable to the crossheads and other parts of engines and other machinery, also in the means employed for lubricating the same and other sliding or frictional surfaces.* (A communication.) Dated November 22, 1867.

The first part of this invention relates to a peculiar construction of "gibs" such as are used in the cross-heads of steam and other engines, and in other mechanical devices having a sliding character or action, and in which the gibs form bearings against guides during the sliding or reciprocating action of the cross-head or other mechanical device which carries them, and is equally applicable to gibs having a fixed or stationary character on or against which the moving parts of machinery bear or slide over. This part of the invention consists in making the gib in sections consisting of a loose or detachable friction plate of superior metal as regards wear and anti-friction properties, the same covering the one side or face of the gib to form the rubbing surface or bearing and main portion or body of the gib of inferior metal constructed or arranged to carry the friction plate, and constituting a back or support to the main portion readily removed, and a new one supplied to the main portion or body of the gib which is exempt from wear. The second part of the invention relates to the lubrication of gibs of a working or movable character, or the surfaces against which they bear or slide.—Patent abandoned.

3310 T. G. F. DOLBY. *The hot water food warmer.* Dated November 22, 1867.

An extension of time for filing the final specification of this invention having been petitioned for, the documents relating to the invention cannot at present be seen.

3311 A. MUNRO. *Improvements in boring or cutting rocks or other substances, and in the means employed therefor.* Dated November 22, 1867.

This invention relates to an improved tool to be used for cutting rocks or other similar substances in mining and engineering operations, and in hewing or cutting stone for building and other structural purposes, and it consists in the application of chilled cast iron, or iron compounded with other substances as the material of which the tools themselves are made. The tool consists of flat discs, with the edge bevelled, or of a bell-mouth shape, so that a sharp or cutting side is left all round them; the tools are retained in holders fixed to the boring head of a boring or cutting machine, and they are manufactured by running cast iron into properly shaped drills in the ordinary manner. In place of forming the tools of a disc shape, they may be made oblong with round or semicircular ends. They may also be made of an elliptical, angular, or other form, a dovetail or other-shaped projection being formed on the back for retaining them in the holder.—Patent completed.

3312 G. WELCH. *An improved mode of, and apparatus or means for, killing whales.* Dated November 22, 1867.

The patentee claims, first, the use of shells filled with gunpowder or other suitable explosive material fixed on the front points of the harpoon and whaling lances, as described. Second, the method of exploding such shells by means of a fuze, which is ignited by pressure and percussion of the opening of the barbs after the harpoon has entered the whale, as described. Third, the method of exploding shells attached to whaling licences by means of a waterproof time fuze contained in a perforated tube inserted in the hollow shaft of the lance, the said fuze being ignited when the lance is fired from the harpoon, gun, or other suitable instrument.—Patent completed.

3313 J. H. BROWN. *A new game called "The queen and her court," to be played with balls and cues or other media for propelling the said balls, and also for the peculiar construction of the table on which the same is played, together with the several mechanical appliances and figures.* Dated November 22, 1867.

These improvements consist in a new game denominated the "Queen and her Court," which game is played with balls and cues, or other propelling media, on a table formed with any required number of holes, somewhat after the construction of a bagatelle board, only that the balls falls completely through into a chamber underneath upon an inclined plane.—Patent abandoned.

3314 G. D. HUGHES. *Improvements in the means of, and apparatus for, consuming smoke and economizing fuel in furnaces of steam boilers and other furnaces.* Dated November 23, 1867.

The patentee claims the peculiar arrangement and application of vertical wires or rods in the door, or box, or respirator, and the projections on the underside of the firebars, and also the combination of diverging and deflecting plates. He does not claim any of the other mechanical arrangements separately, but he claims the combined means, apparatus, and general arrangement of parts as applied to the doors or other parts of furnaces for the purpose of consuming smoke and economizing fuel.—Patent completed.

3315 W. NEEDHAM and J. KITE. *Improvements in apparatus for depurating or changing the condition of fluids in process of decantation.* Dated November 23, 1867.

The object of this invention is to intercept all substances held in suspension, and to purify fluids of every kind in their passage from one vessel to another by means of a portable filtering apparatus adapted between them. The filtering apparatus consists, essentially, of a chamber containing one or more filtering cloths, and having on its exterior connecting tubes and cocks by which it is placed in connection with the casks or other vessels, and through which the fluid is admitted to, and withdrawn from, its interior.—Patent abandoned.

3316 G. H. and E. BOLTON, W. WHITTHREAD, and T. ROBINSON. *Improvements in obtaining motive power, and in apparatus employed therein.* Dated November 23, 1867.

This invention consists, first, in obtaining motive power by igniting and exploding within any suitable engine a mixture of the vapour of a hydrocarbon liquid with atmospheric air or oxygen, when admixture of the air or oxygen with the said vapour, or only a part of the air or oxygen with the said vapour, or only a part of the air or oxygen required, is effected or allowed to take place within a vessel or space outside the cylinder or cylinders, or other part of the engine within which the explosion is caused. Any gas or vacuum engine now in use can be employed, but the inventors prefer those of the improved construction hereinafter described. The said vapour and air or oxygen, mixed as aforesaid, are supplied to the engine by either of the well-known methods of inhalation, or injection; they prefer the former, however, as by it the mixing of the said gases is effected in a simple and efficient manner within the same vessel in which the hydrocarbon liquid is vaporized. Second, the invention consists in employing with engines in which hydrocarbon vapour and air or oxygen are employed an apparatus devised by the patentees, and called "the vaporizer." This consists of a rectangular or other suitably shaped vessel; it contains the hydrocarbon liquid, and is so fitted that heat can be applied to vaporize the said liquid should the atmospheric temperature be insufficient for that purpose. Internally it is divided by partitions, or it is partly filled with a spongy, fibrous, or porous material, which will suck up by capillary attraction the hydrocarbon liquid. The supply pipe of the engine, that is to say, the pipe which conveys the mixed gases to the engine, is connected into the said vaporizer, which is fitted with a pipe so arranged that it can be opened to the air or to a supply of oxygen. When the engine is at work, acting by inhalation, the said pipe is opened, and at each stroke air or oxygen is inhaled through the opening which passes through the vaporizer and supply pipe into the engine. The air or oxygen so sucked in mixes with and takes up in its passage through the vaporizer a quantity of the hydrocarbon vapour, sufficient to form an explosive mixture; or the further quantity of air or oxygen required is added on the engine in any convenient manner. When the engine is worked by injection, a pump is employed to force or suck air through the vaporizer and deliver it thence into the engine. Third, the invention consists in placing between engines in which hydrocarbon vapour mixed with air or oxygen is exploded and the vaporizer described above an interceptor to prevent the flame of explosion (should the valves not be tight from any cause) from travelling backwards into the vaporizer. This consists of a box fitted with wire gauze or small tubes. In practice they prefer to place it in the supply pipe near to the engine. The invention comprises other features.—Patent abandoned.

3317 E. T. HUGHES. *Improvements in telegraphic apparatus.* (A communication.) Dated November 23, 1867.

This invention is not described apart from the drawings.—Patent abandoned.

3318 P. SALMON. *Improvements in the manufacture of gas, combined with its application as a motive power in engines previous to its being burned or consumed, and in generating steam in boilers for the same.* Dated November 23, 1867.

The patentee claims, first, the manner of fitting the tubes in the gas generator, the novel self-acting shut-off valves, scrubbers, and drivers, and the use in combination with these of the feed injector, as set forth. Second, the combined apparatus used for the application or treatment of gas in the manner described for lighting, cooking, warming, generating steam or other purposes, as set forth.—Patent completed.

3319 W. BOULTON. *An improved method of transmitting motive power to potters' wheels, lathes, and other similar machinery for the manufacture of pottery.* Dated November 23, 1867.

This invention consists, principally, in an endless band (made of cotton, hemp, india-rubber, or any other suitable material), to be driven from a grooved or other pulley in either a horizontal, vertical, or oblique position, as may be best suited for the machine to be driven, and to be direct-acting without the aid of discs or long shafting, and to have a number of potters' wheels, lathes, jiggers, or other machines in connection with the making of pottery at one and the same time, and so that the speed of any or all of them can be varied at pleasure or reversed, and, in order to accomplish this, the patentee takes the belt from the first driving pulley in the most convenient manner, and passes it near to a grooved pulley in connection with the machine to be driven. He then fixes a small friction pulley attached to a lever or treadle, or any other convenient appliance, and, when the machine is required to move or revolve, the friction pulley is caused to bring the belt in contact with the driving pulley, and, when the speed is required to be reduced, the belt is partially removed from the driving pulley in order to allow a little slipping, or a hand-wheel or brake may be attached, in order to vary the speed, or the belt may be removed to another pulley of a larger size by a lever, treadle, or other convenient arrangement. If the motion is required to be reversed he moves the belt to the contrary side of the pulley, or brings the return belt in contact with another pulley on the same shaft or spindle. By this means the reversed motion can be varied in speed according to the size of the second pulley. In order to keep the belt at an uniform tension he introduces a balance or tightening weight that will move with the variation of the belt.—Patent completed.

3320 W. MACNAB. *Improvements in marine steam engines.* Dated November 23, 1867.

This invention relates to a previous patent dated February 11, 1862 (No. 354), and consists in disposing the low-pressure cylinders which have trunks, and the high-pressure cylinders which have solid piston rods, horizontally and vertically respectively, or otherwise at right angles, or other convenient angles, to each other, but with both low-pressure and high-pressure cylinders of each pair acting on one crank pin. These improved engines may be used in single pairs, but engines comprising two pairs, or in all four cylinders with the crank of one pair at right angles to that of the other pair, form a very good and steadily working arrangement for large powers—Patent completed.

3321 C. E. BROOMAN. *Improvements in steam generators.* (A communication.) Dated November 23, 1867.

The objects of this invention are to increase the heating surface and the evaporating power of the fuel in tubular steam generators, and the improvements consist, first, in a tubular partition which the patentee fits between the grate bars and the top of the fireplace; and, second, in an independent tubular apparatus which fits in the firebox above the tubular partition, to serve, as required, either as a heater of the feed water, or as a superheater of the steam produced by the generator.—Patent completed.

3322 S. AMPHLET and J. B. FENBY. *Improvements in machinery for ruling ornamental patterns or devices.* Dated November 23, 1867.

The details of this invention are two voluminous to be quoted here. The patentees claim, first, the construction and arrangement of the compound table described, the lower or principal table having a longitudinal motion from end to end of the machine, and the other a transverse motion upon the first or principal table. Second, the construction and arrangement of the parts of mechanism for giving an intermittent sliding motion to the transverse table for the purpose of spacing the pattern. Third, the construction and arrangement of the parts for reversing the spacing mechanism, and for returning the transverse table to its original position on the principal table, substantially as described and illustrated in the drawings. Also the construction and arrangement of parts for determining the position at which the spacing mechanism should be reversed. Fourth, the construction and arrangement of parts for raising and lowering the whole of the pens at each double traverse of the principal table, and for lifting any particular pen or pens on the advance stroke of the said table, as the pattern being ruled may require. Fifth, the construction and arrangement of the parts for shifting any row of pens without disturbing the spaces of the pens, with respect to each other. Sixth, the construction and arrangement of parts for raising and lowering the pen carriage, substantially as described. Seventh, the general arrangement or combination described of the parts of machinery for ruling ornamental patterns or devices. Lastly, constructing the pens of machinery for ruling ornamental patterns or devices with a long bearing surface or edge, as described.—Patent completed.

3323 W. MORT. *Improvements in preserving meat, and in apparatus employed therein.* (A communication.) Dated November 23, 1867.

This invention is not described apart from the drawings.—Patent completed.

3324 J. H. JOHNSON. *Improvements in breech-loading fire-arms, and in cartridges for the same.* (A communication.) Dated November 23, 1867.

This invention is not described apart from the drawings.—Patent completed.

3325 M. A. HAMILTON. *Improvements in the manufacture of railway rails.* Dated November 25, 1867.

This invention relates, chiefly, to the construction of rails of iron and steel, the two metals being combined in such a manner that the head of the rail is covered on the top and sides with steel, the head, neck, or web and base of the rail being of iron. The whole rail is rolled or drawn from a pile or faggot consisting of bars of iron and steel, the steel and iron being welded together during the process of rolling. The invention also relates partly to the production of an iron railway rail formed partly of old rails having the top and sides of its head wrapped around with the steel, the whole being welded together during the rolling process.—Patent completed.

3326 T. BARTON. *An improved cribbage board.* Dated November 25, 1867.

This invention consists in forming within the top of the board two sets of numerical indicators and a trump card register (making in all five indicators), as also a register at each end denoting the number of games scored; the register denoting the "ace" in each suite, or trump card turned up or cut at each dealing, and the numerical indicators (singly or combined) registering the progress of the game, which are both to be seen at one glance.—Patent completed.

3327 F. BROWN. *Improvements in kitchen ranges.* Dated November 25, 1867.

This invention is more particularly applicable to what are known as close fire ranges when the range is made with an oven on one side of the fire and a boiler at the back; or when made without any boiler the patentee heats the oven or ovens by two distinct flues from the fire. First, the top of the oven is heated by a flue from the fire passing over it; this flue has an outlet into the chimney, and the draught is regulated by a damper in the usual manner. Second, the bottom, back, and side of the oven furthest from the fire are heated by a flue passing, by preference, from the bottom of the fire, or from the side of the fire close to the bottom; this flue passes under the oven, and rises at the back or side, or both, and then up the same outlet to the chimney as the flue which passes over the top of the oven; or it may have a separate outlet or outlets to the chimney, and the draft may be regulated by an independent damper or dampers. The side of the oven next the fire is heated in the ordinary manner by its close proximity to the fire, and is protected as usual with a firebrick or iron shield to prevent its becoming overheated.—Patent completed.

3328 G. TURNER. *Improvements in the construction of packing cases, and in the mode of locking the same to secure them against clandestine opening.* Dated November 25, 1867.

This invention is not described apart from the drawings.—Patent completed.

3329 T. L. GREENWOOD. *Improved means or apparatus for dyeing piece goods indigo blue.* Dated November 25, 1867.

This invention consists in the application and use of a pair of rollers submerged a suitable depth in the dye liquor, and placed at any convenient distance apart, and parallel to each other, so arranged and operated by chain and wheels, or other suitable gearing, that the fabric to be dyed may be first wound upon one of these rollers, then unwound therefrom and wound upon the other roller, and so on, thus traversing the fabric alternately from one roller to the other in the dye liquor until the desired effect is produced.—Patent abandoned.

3330 T. J. MAYALL. *Improvements in means or apparatus for accumulating and delivering sheets of paper or other fabrics.* Dated November 25, 1867.

The object of this invention is that sheets of paper, or other fabric, as received from a printing press or other supply may, be accumulated in regulated quantities, and that when the desired number have been accumulated they may be delivered on to a table or other receiver. For this purpose the separate sheets are received between pairs of endless tapes which are kept distended by rollers. These receiving tapes conduct the sheets to the surface of a cylinder, which may be called the accumulating cylinder, and to which the sheets are borne by other endless tapes formed of india-rubber web or other elastic material. These elastic endless tapes are kept extended by means of extending rollers, by which, aided by guide rollers, they are caused to bear against a considerable portion of the surface of the accumulating cylinder. One of these extending rollers is supported on arms capable of being actuated so that at one time the portions of tapes passing over it may, aided by other arms, act to facilitate the accumulation of sheets on to the accumulating cylinder, and then,

Digitized by Google

when desired, be moved to cause the accumulated sheets, aided by other arms or guides, to pass between delivery rollers, by which they are delivered to a table or other receiver.—Patent abandoned.

3331 G. B. GALLOWAY. *Improvements in merchants' ships and other vessels and appliances connected therewith.* Dated November 25, 1867.

Provisional protection has not been granted for this invention.

3332 R. WARD. *Improvements in machinery for spinning or twisting tobacco.* Dated November 25, 1867.

The patentee claims the use of an arm running down the whole length of the table, or as nearly so as circumstances require, to enable the spinner to operate upon the mechanism the use of cones to regulate the speed, and the use of loose shears in connection with one of the cones to withdraw the motive power from the reel. He also claims the arranging machinery for spinning or twisting tobacco, substantially as described.—Patent completed.

3333 T. CHALMERS. *Improvements in machinery for producing seamless tubes.* (A communication.) Dated November 25, 1867.

This invention is not described apart from the drawings. —Patent completed.

3334 A. V. NEWTON. *An improved construction of rotary steam engine.* (A communication.) Dated November 25, 1867.

This invention relates to a novel construction of rotary engine, which admits of being driven in opposite directions at the will of the attendant. The engine consists of a cylinder through the end plates of which passes a driving shaft carrying a cam or block mounted concentric with the cylinder. This block is made to work steam-tight against the end plates. It is formed with recesses in its periphery to receive hinged pistons which fit closely in their respective recesses, except when forced out by the impelling power of the steam. In one position of the cylinder metallic packing with tapering ends are provided, which forms a steam top between the inner periphery of the cylinder and the periphery of the block or cam, and it serves to press down the pistons (as they are brought round by the rotation of the block) into their respective recesses. Two sets of pistons are provided, one set to act in one and the other in the opposite direction. Each set may consist of two or more pistons. At opposite sides of the cylinder are ports or openings for the admission of steam from the boiler. These parts are opened or closed according to the direction of rotation required for the engine. From each of these ports the steam passes to one of two annular steam chests made in the end of the rotating cam or block. These steam chests are divided into two equal parts, from each of which a passage leads off to the back of a piston. The steam, therefore, is caused to act on the back of the pistons, and thereby impart the required propelling power to the engine.—Patent completed.

3335 W. F. STANLEY. *A new instrument to be called a meteorometer.* Dated November 25, 1867.

This invention refers to an instrument which the inventor calls a meteorometer, the purpose of which is to predict the probable weather. The construction of this will combine in one instrument the following indications:—The specific weight, the direction, the force, the temperature, the hydrometric and the electric state of the atmosphere; also will indicate whether the mercurial column is rising or falling; also the combined action of weight and direction of the atmosphere acting together, giving the meteorological effects of their combined action by indication on one dial; also the amount of rainfall in a given time. A compensating clock will be generally placed upon the face of the instrument. The details of the invention are voluminous.—Patent abandoned.

3336 R. M. LETCHFORD. *Improvements in the manufacture of cigar and other lights.* Dated November 26, 1867.

The first part of this invention has reference to the composition for burning at the end of the stem. This part of the invention consists in forming a paste of amorphous phosphorus, with a small quantity of powdered glass and dissolved gum, and a proportion of water. He applies this paste to the end of stems of suitable material, and finishes in the way that Vesuvian cigar lights are now finished. The proportions of the materials he uses are:—Amorphous phosphorus, 4oz.; powdered glass, 8lb.; gum arabic, 3lb.; and water, 4 pints. The second part of the invention relates to the stems of cigar and other lights. Stems of cigar and other lights have hitherto been made of wood or glass. Now, according to this invention, he makes them of bone.—Patent completed.

3337 W. SIM. *Improvements in arrangements or apparatus for watering and cleansing streets and roads, and for speedily removing snow.* Dated November 26, 1867.

The features of novelty comprised in this invention are, first, the using of permanently fixed perforated pipes, supplied from the water mains, and controlled by valves or hydrants for watering and cleansing streets and roads, and also for removing snow therefrom, when not accompanied by too intense a frost; and, second, the using of travelling furnaces for liquefying snow when accompanied by hard frost, or when it may be inconvenient to use water for removing it.—Patent completed.

3338 H. GREENHALGH. *Certain improvements in mechanism or apparatus employed for preparing cotton or other fibrous substances.* Dated November 26, 1867.

This invention relates to that portion of apparatus employed for preparing cotton and other fibrous substances termed "drawing frames," and to that part of drawing frames known as the "sliver-stop motion," used for stopping the particular "head" of the machine when any particular sliver breaks, which has hitherto been effected by means of the balanced "spoon-stop motion" as a substitute for which the present invention is designed. The improvements consist in the novel application and use of a balanced lever, having at one end a vertical rod with curved guides at the upper end, the opposite end of the lever being provided with a weight adjustable on a screw, so as to adjust the balance of the lever. The sliver passes from the delivery rollers through a tension eye or guide, also adjustable, and over the aforesaid curved guide, and thence through a "trumpet mouth" into the ordinary can or receiver, and so long as the sliver remains united, the lever is balanced by its weight, but when disconnected the weighted end of the lever falls, and the end thereof comes in contact with the ordinary rocking bar which actuates the ordinary stop motion of the machine.—Patent abandoned.

3339 J. P. SMITH. *Improvements in the manufacture of cutting tools, and in the construction of tool holders.* Dated November 26, 1867.

The patentee claims, first, manufacturing cutting tools by casting them of the form required in chill moulds, the said tools being cast from molten steel, or from molten alloys of steel or iron, or of steel and iron with tin or with copper, or with both tin and copper, or with other metals, substantially as set forth. Second, the sheath cutting tool holder, constructed substantially as described and shown in the drawings. Third, the several constructions of cutting tool holders shown on the drawings, in which a cam, or wedge, or both a cam and wedge, is or are employed to secure and adjust the cutting tools, substantially as set forth.—Patent completed.

3340 J. P. SMITH. *An improved mode of coating and uniting metals with metals.* Dated November 26, 1867.

The patentee claims coating or uniting one kind or quality of hard metal with another kind or quality of hard metal by superimposing or bringing them into contact with each other when both are in the molten state.—Patent completed.

3341 E. TOWNSHEND. *Improvements in tobacco pouches.* Dated November 26, 1867.

This invention consists in forming the bottom and ends of such pouches with a corrugation or corrugations along them, so that they may be capable of expanding or opening out in a similar manner to the sides and end of a bellows. —Patent completed.

3342 C. E. PENNY. *Improvements in envelopes.* Dated November 26, 1867.

This invention applies especially to that class of envelopes known in the trade as "pocket envelopes," wherein the letters or contents are introduced at one end, which is left open for that purpose, and which is then closed by a flap which is gummed or otherwise fastened down. The two sides are first folded over somewhat in the usual manner, and gummed or pasted, but the patentee makes this joint by forming one side somewhat in a half lozenge shape, so that when folded over the obtuse angle slightly overlaps the centre and other side like a right-angled triangle, the base of which is about equal to the width of the envelope, so that, when the sides are folded over, they overlap only at one end, forming a joint diagonally from one corner of the envelope to about the central point of the same. The two end flaps are in the form of Isosceles' triangle, whereof the base is equal to the width of the envelope, and the height (with the apex rounded or cut off) such that, when folded over, they overlap in the centre in such a manner that the lower flap when folded up completes the form of the pocket, and the upper flap when folded down overlaps the former, and is gummed on to both side flaps and the lower end flap at the same time, so that, whether the envelope is further secured by sealing wax or not, it is impossible to open the same and abstract any of the contents without detection.—Patent completed.

3343 J. A. and J. HOPKINSON. *Improvements in steam boilers.* Dated November 26, 1867.

The patentee claims, first, the adaptation and application to boilers of a steam chamber or chambers formed or inserted below the surface of the water, such chamber or chambers being in communication with the upper steam space and the steam pipe, as described. Second, the use of such steam chamber or chambers as a means of strengthening the boiler, as described.—Patent completed.

3344 J. and J. HINKS. *Improvements in safety cans or vessels for containing, measuring, or storing petroleum, oil, and other volatile inflammable liquids.* Dated November 26, 1867.

In the axis of the nozzle or neck of the can or vessel is a rod working in bearings in the shoulder of the can immediately below the neck or nozzle. The said rod carries a disc or valve fitting against the bottom of the neck or nozzle. By raising the said rod the valve is closed, and by depressing the rod the valve is opened. The top of the rod is screwed, and the cap or cover of the nozzle or neck has a screwed hole in it which takes upon the screw on the top of the rod. By screwing the cap or cover on to the top of the rod it screws down upon the top of the nozzle or neck, and at the same time raises the valve, pressing the valve against the bottom of the nozzle or neck. On the valve is a conical metallic tube, the upper part of which fits accurately in the nozzle or neck of the can, the said conical tube being perforated with small holes. As the valve rises or falls the conical tube slides up or down the nozzle or neck of the can. When the valve is depressed liquid can be poured into the can, or be removed therefrom, the liquid passing through the fine holes or perforations in the conical tube. The holes or perforations in the conical tube are so fine that flame will not pass through them, and if the liquid in the neck or nozzle accidentally takes fire the flame will not pass through the said fine holes or perforations into the can or vessel.—Patent abandoned.

3345 W. R. LAKE. *Improvements in breech-loading fire-arms, and in cartridges for the same.* (A communication.) Dated November 26, 1867.

This invention is not described apart from the drawings. —Patent completed.

3346 W. R. LAKE. *Improvements in electric telegraph apparatus.* (A communication.) Dated November 26, 1867.

This invention consists, partly, in a mode, and instruments for, operating and working long submarine cable lines of telegraph by the sound, or printing instead of the "galvanometer reflector" system, and also in devices for protecting such instruments and cables from any injurious effects of lightning or atmospheric electricity.—Patent completed.

3347 J. HUDSON. *Improvements in machinery for the manufacture of paper.* Dated November 26, 1867.

Here the inventor covers the couching rolls, and first and second pairs of press rolls, with stout india-rubber jackets, by which means he is able to dispense with the woollen jackets and endless felts, as at present arranged in this description of machinery, but the endless wet felt may be employed for carrying the sheet of paper to the rolls, and then, by passing under, may take it up again to the second press rolls, or, where no second press rolls are used, then on to the drying cylinders. A felt is worked with the first press roll as well as being covered with india-rubber. The second press roll will not require any felt, nor will the coucher require any felt jacket, as at present. —Patent abandoned.

3348 C. T. HIGGINBOTHAM. *An improved arrangement or construction of furnaces to be used for preventing smoke and effecting economy of fuel.* Dated November 26, 1867.

This invention consists in using firebars having a hollow web, or partly hollow and partly tubular web, which bars may or may not also have in addition to the hollow or tubular web certain lateral openings through which air may pass into the overlying stratum of fuel. Across the inner end or side of the furnace a hollow bridge or chamber is formed, the ends of the bars passing into the hollow bridge or chamber through its front wall or side, the bars thereby constituting air passages into the chamber. As the air passes through the bars, its temperature is raised, and it consequently passes as hot air into the chamber, from which it escapes through one or more suitably formed openings, and, mixing with the gases escaping over the bridge from the incandescent fuel, causes their complete combustion, and therefore prevention of escape as smoke. —Patent completed.

3349 J. H. JOHNSON. *Improvements in the treatment of rabbit, hare, and other skins.* (A communication.) Dated November 26, 1867.

This invention consists in substituting for the preparation of mercury hitherto employed in the process known as "carrotting" of any hydrocarbonated or other substance capable of decomposing nitric acid into nitrous acid. As examples of those hydrocarbonated substances from which good results have been obtained, raw or refined sugar, gum, and starch, may be mentioned.—Patent completed.

3350 A. V. NEWTON. *An improved steam injector for supplying water to steam boilers or tanks.* (A communication.) Dated November 26, 1867.

The steam injector, when applied as a boiler feed, consists of a steam-tight cylinder or box, made of boiler iron or other metal, which is connected by a pipe with a well, cistern, or other reservoir of water, the bottom of the cylinder being placed at the height to which the water is required to rise in the boiler. The cylinder is also connected with the boiler by two pipes, one of which is used for the passage of steam from the boiler into the cylinder, the other for the passage of water from the cylinder into the boiler. These pipes are governed by taps or valves, so that the communication between the boiler and the cylinder, and cylinder and boiler, may be shut off or opened, as required. The pipe connecting the cylinder with the well, cistern, or reservoir is also governed in like manner by a tap or valve. The cylinder being empty, and all communication with it being shut off, by opening communication between the boiler and cylinder by means of the pipe used for the passage of steam, a jet of steam from the boiler fills the cylinder. When the cylinder is full of steam, the communication between the boiler and the cylinder is shut off, and the communication between the cylinder and the well, cistern, or reservoir of water is opened. The steam rushes from the cylinder into the water, and, condensing in contact therewith, creates a vacuum in the cylinder, when the water immediately rises up and fills the cylinder. The communication between the cylinder, and well, cistern, or reservoir of water, is then shut off, and the communications between the boiler and the cylinder, by means of the pipe used for the passage of steam and between the cylinder and boiler, by means of the pipe used for the passage of water are opened, and the steam forces the water from the cylinder into the boiler, entering the cylinder and imparting heat to the water, keeping the water in the boiler on a level with the bottom of the cylinder, and making it cover the entrance of steam pipe into the boiler. This entrance being thus covered by the water, the action of the steam on the water in the cylinder ceases until the end of the steam pipe leading to the boiler is again uncovered by the sinking of the water in the boiler. When this takes place, the steam will again act on the water in the cylinder, forcing the water into the boiler, and up to the same level, and covering again the entrance of steam pipe into the boiler. It follows that so long as there is any water in the cylinder, the water in the boiler will stand on a level with the bottom of the cylinder. A water gauge put on the cylinder will indicate the depth of water therein.—Patent completed.

3351 A. V. NEWTON. *Improved apparatus for preparing paper pulp.* (A communication.) Dated November 26, 1867.

This invention relates to the use of a circulating pump in combination with a wood or straw pulp digester, whereby the digesting liquor is forced to circulate continuously through the vegetable fibrous mass to be pulped. In combination with such a digester and pump it is also proposed to employ a coil or other means of heating the circulating liquor on its passage to and from the digester.—Patent abandoned.

3352 E. H. BENTALL. *An improvement in the conversion of iron into blooms.* Dated November 26, 1867.

This invention relates to the utilization of the cuttings of iron produced in workshops where boring, turning, planing, and other cutting or fashioning tools are used by the conversion of those cuttings which have hitherto possessed little commercial value into blooms at a cost considerably below the cost of manufacturing ordinary wrought iron. In order to attain this end the patentee forms cases of sheet iron of any approved capacity, say of a size equal to receiving one hundredweight of the cuttings, and in these cases he packs as much of the waste material or turnings, borings, planings, and filings of iron as they will contain. The packed cases he submits to the heat of a reverberatory furnace, and when brought to a white heat, or thereabouts, he removes them from the furnace and subjects them to the action of stampers, or other severe pressure, which, owing to the highly heated and partially softened state of the metal, will convert them into solid plastic masses or blooms possessing a fair grain, and capable of being employed for a variety of purposes. —Patent completed.

3353 M. A. HAMILTON. *Improvements in lamp burners.* Dated November 26, 1867.

This invention relates to lamp burners for burning mineral oils, and the nature of the invention consists in the novel construction of the burners, whereby the wick can be lighted without removing the globe or chimney An aperture is formed in the side of the body of the burner, which aperture is closed by a sliding valve acted on by a spring which keeps the valve closed, except when held open by the hand during the act of lighting the wick. —Patent abandoned.

3354 C. COATES. *Improvements in machinery for cutting or dressing stone, and in apparatus connected therewith.* Dated November 27, 1867.

This invention consists in improved machinery for cutting and dressing stone by means of circular discs or tools, or their equivalents, the discs being mounted and

Digitized by Google

working in the manner described, and shown in the drawings, and constituting a dressing tool or instrument of a new character. The stone intended to be dressed is placed on a movable table to which a reciprocating motion is given, so as to bring the stone under the operation of the dressing tool. In some cases the stone may be supported upon a table, and a reciprocating motion is given to the dressing tool in the manner described. The invention also relates to apparatus for sharpening the operating edges of the discs forming the dressing tool by grinding them in the manner described. The invention is not fully described apart from the drawings.—Patent completed.

3355 J. H. JOHNSON. *Improvements in the construction or arrangement of piles or faggots for wrought-iron beams, girders, or bars of different forms.* (A communication.) Dated November 27, 1867.

The patentee claims, first, the construction and use of a pile or faggot composed of one or more bars for the web, and any appropriate number of bars for the flange or flanges, the said bars being arranged and permanently secured together by rivets or bolts, substantially as described and illustrated in the drawings. Second, the construction and use of a pile or faggot composed of one or more bars for the web for each flange, the whole being held together by rivets or bolts, substantially as described and illustrated in the drawings. Third, the construction and use of a pile or faggot composed of one or more bars for the web, and any desired number of bars for the flange or flanges, the said bars being arranged and permanently secured together by rivets or bolts, substantially as described and illustrated in the drawings. Fourth, the construction and use of a pile or faggot (for cruciform and other shaped beams or girders) composed of bars arranged and secured together by clamps, substantially as described and illustrated in the drawings. Fifth, the construction and use of a pile or faggot composed in part of a solid bar or bars with a rib or ribs, and in part of bars riveted together and wedged to the said ribs or ribs, substantially as described and illustrated in the drawings. Sixth, the construction and use of a pile or faggot consisting of a solid bar or bar having a rib or ribs confined between bars by riveting the same to any desired number of intervening bars whose aggregate thickness is less than the said rib or ribs, all substantially as set forth in the specification and drawings.—Patent completed.

3356 W. FOWLER and J. GRIFFITHS. *Improvements in the manufacture of the tyres of railway and other wheels.* Dated November 27, 1867.

This invention is particularly applicable to the manufacture of the tyres of railway and other wheels from Bessemer steel scrap. The patentees heat the steel scrap in a furnace, and hammer and roll it to the section or size required. They afterwards coil or bend pieces of suitable length into a circular figure, and in this way form rings. They prefer to roll the bar of a taper figure in cross section. When the bar is coiled into a ring, the narrow edge being made the inner or concave side of the ring, the metal thickness on the said concave side and the ring becomes of uniform thickness. The ring may be made of segmental pieces instead of from a single piece. They take a series of rings made in the manner described and build or place them upon one another, so as to form a pile, the rings being so arranged that they break joint with one another. The pile of rings is placed in a heating furnace, and when raised to a welding heat is taken to a hammer and placed upon or in the anvil or bed of the said hammer. The said anvil or bed is of a dish shape, so that the external part of the pile of rings is surrounded by the projecting sides of the said bed or anvil. The hammer is provided with a mandril or punch which corresponds in size with the hole in the pile of rings. The mandril or punch may also be made to increase the size of the holes in the rings if necessary. By the operation of the hammer the pile of rings is welded into an annular bloom or blank, the bloom or blank being turned over and heated from time to time for effecting a uniform weld, the external and internal diameters being preserved by the dish-shaped bed or anvil and mandril of the hammer. The bloom or blank thus made is taken by the weldless tyre mill and rolled into a tyre having the required section.—Patent completed.

3357 A. M. CLARK. *Improvements in ornamenting gauze and other fabrics.* (A communication.) Dated November 27, 1867.

This invention relates to the production of designs of all kinds and colours presenting either a bright or dull appearance or mall on light and other fabrics, this ornamentation being especially applicable to gauze, tarlatan, tulle, and other light fabrics. The following is the mode in which the inventor carries out the invention. He takes coloured resin or sealing-wax, reduces it to powder, and spreads it on a table. He then places the fabric to be ornamented on the pulverized matter, and impresses any suitable design thereon by the aid of an adhesive mordant, which causes the pulverized wax to adhere at all points, where the mordant is absorbed after the fabric is dry. He brushes off the surplus wax, and subjects it to the action of heat in a stove or otherwise, by which means the particles of resinous matter become fixed and assume a brilliant coloured effect. He may also employ transparent wax in grains, which he sprinkles or otherwise applies on the fabric to be ornamented; these grains or powder are then melted by the application of heat, and form a transparent bead.—Patent completed.

3358 A. V. NEWTON. *Improved apparatus for making extracts.* (A communication.) Dated November 27, 1867.

This invention consists in an improved arrangement of apparatus for extracting tannin from bark, or the strength from any other substance from which extracts are made or obtained, by means of which upward hydraulic pressure is applied to the substance under treatment. Reference to the drawings is essential for a full description of the invention.—Patent completed.

3359 E. BELKNAP. *Improvements in the treatment of the solution of malt for brewing.* Dated November 27, 1867.

This invention consists, first, in cleansing or purifying the wort after washing and before fermentation by means of the alkalies, alkaline earths, alkaline hydrates, and alkaline silicates, or any or all of them, either separate or mixed, and thereby causing a more complete coagulation and separation of the albuminous elements held in solution than can be effected by boiling only, as now generally practised. Second, in effecting the precipitation of albuminous and other matters from the wort by the addition to the same of an insoluble ponderable body in a finely pulverized state, capable of being mechanically diffused through the wort, together with alkalies, alkaline earths, alkaline hydrates, and alkaline silicates, as described.—Patent completed.

3360 H. F. GARDNER. *Improvements in the means of, and apparatus for, treating metals and minerials, in order to produce their oxides or other chemical or mechanical combinations, and to separate metals from their ores or from their alloys.* (A communication.) Dated November 27, 1867.

This invention relates to certain improvements in the means of and apparatus for treating metals and minerals for the purpose of producing various chemical or mechanical combinations or changes, such as the production of their oxides, carbonates, or other salts; also for the purpose of separating metals from their ores, or from their alloys, and of effecting these objects by a continuous operation if required. This mode of operation consists, first, in melting the metal or mineral to be treated or acted upon in a suitable crucible, and raising its temperature to the degree necessary for subsequent operations. From the bottom of this crucible or melting pot the metal is allowed to flow in one or more fine jets or streams. Immediately after the stream of melted metal leaves the orifice of the crucible it encounters a jet or blast of atmospheric air, or other gas or vapour, which is projected directly across the jet of metal with considerable force. The effect of this blast is, first, to subdivide the metal into a metallic dust of exceeding fineness, and, if the metal is of a character that has its melting point below that of oxidation, and its temperature is but just above that, the metal will be deposited in the form of an impalpable powder. In the second place, if the temperature of the melted metal is sufficiently high to produce a chemical combination with the blast, the metal being in a state of minute subdivision, is instantaneously acted upon chemically by the blast, and converted into an oxide or a salt, according to the nature of the blast employed. If atmospheric air be injected, oxides will generally be produced, but if the blast be composed of some other gas, some other chemical reaction will be produced corresponding to the chemical character of the blast, or some other chemical reaction may be thereby prevented.—Patent completed.

3361 J. S. SMITH. *Certain improvements in apparatus for ventilating buildings and other similar purposes.* Dated November 27, 1867.

The patentee claims the use and application of a movable cap, cover, plate, or equivalent for opening and closing the upper end of air shafts used as ventilators, for the purpose of excluding dust, dirt, and extraneous matters, irrespective of the form thereof, or of the mechanical means employed to effect their rise or fall. Second, the general construction, arrangement, and combination of the apparatus for the purpose, as described.—Patent completed.

3362 J. M'FARLANE and G. BARKER. *Improvements in the permanent way of railways.* Dated November 27, 1867.

Here the inventors cast longitudinal sleepers or bearing plates in one piece with a rail, the upper or wearing surface of which is "chilled" to produce a good wearing surface. They prefer to make the cast sleeper or bearer of an arched form, or hollow on its under side, so that it may rest on the ballast without shifting, and to form along the centre of its upper surface a vertical web or rib, having a head upon it which is to form the rail, the upper surface of the head being chilled to produce a good wearing surface. The vertical web or rib is strengthened by flanges which connect it with the top of the sleeper or bearer. In order to connect together such combined rails and sleepers end to end, a piece of T or other iron may be employed, the T-iron being placed on the under side of the sleepers so as to overlap their ends, and being affixed thereto by bolts. Lugs or flanges may also be cast on the under side of the sleepers or bearers to hold the fish plates from moving laterally. The rails may be kept to gauge by wrought iron tie bars at intervals, the tie bars being passed through slots in the web of the rail, and fixed with gibs and cotters. The foregoing are the main features of the invention.—Patent abandoned.

3363 S. A. CHASE. *Certain new and useful improvements in the running mechanism of car and carriage trucks of any nature.* Dated November 27, 1867.

The object here is to obtain an increase in power for propelling a railway or other carriage, as well as to reduce the friction upon the bearings of the rolling portion of such car. The invention also has for its object to start the carriage for a short distance with the application of very little power, its value for this purpose being chiefly applicable to horse railway cars. The invention consists in the employment of two sets of axles and wheels, one disposed over the other, and with the load resting upon and sustained by the upper axles, the rollers of which rest and roll upon the lower axles, or upon small hubs applied to the lower wheels, the journals of such lower axles being upheld in vertically sliding boxes, substantially as explained. The invention further consists in a mode of applying the journals of the upper axles to their boxes or bearings so as to allow such to roll along forward within such box a short distance, until the vis inertia of the weight of the carriage is overcome, and impetus created upon such carriage by the employment of very little power, as well as to keep the journals well lubricated, substantially as explained.—Patent completed.

3364 W. R. LAKE. *An improved spring hinge.* (A communication.) Dated November 27, 1867.

This invention relates to a simple device which is well adapted to take the place of ordinary door and other hinges, or may be used in connection with the same simply as a spring. The invention consists, chiefly, in constructing and arranging the two parts or leaves of the hinge in such a manner that one part, or a portion of the same, forms the spring to act upon the other part.—Patent completed.

3365 M. A. HAMILTON. *An improved cutting implement, more especially designed for opening cases or cans formed of sheet metal.* Dated November 27, 1867.

This implement is provided with a point at one end which is forced through the sheet of metal to be cut, and forms a centre or fulcrum around which the implement is turned to force its cutting blade through the metal. The blade is made adjustable, and its distance from the fulcrum point can be varied according to the required size of the aperture to be formed. The blade is secured in any position by an eccentric at the back of the implement.—Patent abandoned.

3366 A. MACKIE. *Improvements in apparatus for composing and distributing type.* Dated November 28, 1867.

This invention consists in the use of paper, or other suitable material, previously and specially perforated or slotted, to control or regulate the selection of type by self-acting mechanism in connection therewith, both for setting and distributing printers' type.—Patent completed.

3367 R. H. BENTHAM. *Improvements in the method of, and apparatus for, facilitating the flow of liquids from barrels or other closed vessels.* Dated November 28, 1867.

This invention consists in the novel application and use of an elastic or compressible bag, bladder, or vessel, which may be made of caoutchouc, gutta-percha, membrane, or other material, and such bag is to be enclosed within the barrel, and communicate with the atmosphere, by means of a tube passing through the bung or stopper closing the opening to the barrel. When the barrel or vessel is full of liquid the air is expelled, and the bag is compressed thereby, but as the liquid is withdrawn the air passes down the tube and expands the bag, exerting pressure on the liquid, and facilitating the flow without direct contact therewith.—Patent abandoned.

3368 W. PALMER. *Improvements in the shape and manufacture of horses' shoes.* Dated November 28, 1867.

Instead of taking a plain flat bar of iron as the foundation for horse shoes, the patentee takes a bar of a sort of angle iron, which has been formed into the proper shape by means of rollers, or by other suitable and proper apparatus. The section of the bars of iron which he uses is in the form of a wedge with the point downwards, and with the upper face or surface of the wedge prolonged in one direction, so as to form a projection on one side of the upper face of the wedge. The wedge point of the bar forms the under or downward portion of the shoe and the flat side of the bar the upper portion.—Patent completed.

3369 M. H. and L. H. LARMUTH. *Improvements in water meters and water-power engines.* Dated November 28, 1867.

This invention relates, generally, to those water meters and water-power engines which have reciprocating pistons, and in the first place more particularly to those meters or engines having pistons, the movements of which are controlled by rotating shafts through cranks or their equivalents. The object of this portion of the improvements is to give a certain amount of elasticity to the piston, or to each end of the cylinder, or to parts in connection with each end of the cylinder. This may be effected by forming a portion of the surface of the piston of caoutchouc, or other suitable flexible material, the water acting on the said flexible material from either side of the said piston; or the said flexible material may be fitted to the ends of the cylinder, or be connected therewith, the water having access in all cases to the flexible material, the flexible material being at liberty to yield to a certain extent in either direction, so as temporarily to increase or diminish the capacity of the cylinder, or the portion of the cylinder contained between the piston and either end of the cylinder. The second portion of the invention consists in fitting the cylinders of water meters with linings of glass, earthenware, pottery ware, porcelain, or other similar material, or with metallic linings glazed, enamelled, or coated with a vitrified substance, or with vitrified substances.—Patent abandoned.

3370 E. T. HUGHES. *Improvements in tea and coffee pots.* (A communication.) Dated November 28, 1867.

This invention consists in constructing an area around the upper and the inside portion of the pot, and providing or forming upon the lid of the pot one or more projecting rims extending downward therefrom, nearly to the bottom of the said area, and also providing a tube or nozzle, or a portion thereof, conducting from the area into the nozzle proper, which nozzle has a cap fitted closely thereto, all being so constructed that, when the coffee or tea is put to steeping or boiling in the usual way (having supplied the area with water), the fragrance and full substance is retained within the body of the pot until desired for use.—Patent completed.

3371 T. and B. CARTER and J. LISLE. *Improvements in machinery or apparatus employed in the preparation of wool or other fibrous substances technically known as condensers.* Dated November 28, 1867.

This invention relates to means of working the rubbing rollers employed in these machines, and the improvements consist in the application and use of a cam or skew wheel for producing the usual traverse motion, or for giving reciprocatory motion to the rubbing rollers. This cam is mounted on a horizontal rotary shaft, placed in bearings opposite to one end of each pair of rubbers, about centrally with the two surfaces which are in contact, and a swivelling hook is attached to each rubber, which hook clips on the cam or skew wheel (one on each side), so that one cam gives motion to both top and bottom rubber, each moving in opposite directions.—Patent completed.

3372 W. COTTON. *Improvements in machinery or apparatus for cutting woollen and cotton, corduroy, or other similar fabrics.* Dated November 28, 1867.

The patentee claims, first, the giving or producing reciprocatory motion to the cutting knives while the fabric to be cut has continuous motion. Second, having the knife guide points round and to project at least one inch beyond the points of the knives.—Patent completed.

3373 T. ROSE and R. E. GIBSON. *Improvements in machinery or apparatus for separating and cleaning seeds.* Dated November 28, 1867.

This apparatus consists, essentially, of two rotating separating screens, of cylindrical or other suitable shape, placed in a sloping or angular position the one within the other. These screens are constructed of wirework, or of perforated metal, or other material, the inner one having elongated openings, and the outer one circular or nearly circular openings; they are supported on suitable framework, and are made to rotate by power applied in any convenient manner. The seeds (linseed and rape seed) are fed through a hopper or pipe into the inner screen; as the screen rotates, the linseed, it being of a flat rounded shape, passes through the elongated openings into the annular space between the screens, but the rape seed, it being larger in diameter than the width of the elongated openings, is retained within the inner screen. At the lower end of the screens the seeds fall into separate spouts or chambers. During the separation of the seeds, as described, the earthy and other foreign substances, as well as the very small and inferior seeds, pass through both screens, and are collected in a casing which partly surrounds the screens, and are delivered in a third spout or vessel.—Patent abandoned.

3374 E. T. HUGHES. *An improved sprinkler for powdered substances.* (A communication.) Dated November 28, 1867.

This invention consists, principally, in a novel construction or formation of the interior of the cup or vessel,

Digitized by Google

whereby the material or substance contained in it is made to always move or fall toward an opening made at or near the centre of its under side or base, in combination with a valve so arranged in such opening that it can be opened or closed at pleasure, and thus, when opened, enable the material with which the vessel is filled, or partially so, to be discharged and sprinkled through it upon the article of food which it is desired to season.—Patent completed.

3375 E. T. HUGHES. *Improved machinery for folding and pressing the edges of elastics used in boots and shoes.* (A communication.) Dated November 28, 1867.

This invention is carried out as follows:—On a table there are two apparati, each connected by a rod to a treadle underneath the table, in such manner that the rods are raised or lowered by the foot at pleasure. A guide is introduced into an opening or recess for each elastic, then the stuff is placed in its proper position, and the stuff-holder fixed, after which the guides are removed, and two plates are employed for enabling the edges of the elastic to be plied or folded. There are two irons fixed to one of the said rods, and they are heated on a stove placed at the back, a rotary motion being given to the rod for that purpose, and when the irons are heated, they are returned to the openings for the elastics, after which the treadle is acted upon, and the two irons brought to the level of the plates which rest on the said table for enabling the edges of the elastics to be plied or folded, At the same time that a transverse handle fixed to the irons is acted upon by the hand, a lever, working on a cross rod, also fixed to the said irons, is brought forward, carrying the irons forward with it over the stuff. The plates are now drawn back, and the treadle slightly lowered, so as to balance the weight of the two irons, and then the irons are drawn backwards and forwards several times for pressing the folds, after which they are returned to the stove. The elastics are now placed in the other apparatus, and a stamp caused to act by means of an eccentric and handle on a heated plate of iron, so as to press the folds together. In order to cement the elastics between the folds they are taken to the other apparatus, so that there is no time lost, for while the heating is being performed at one side, the apparatus is at work at the other side.—Patent abandoned.

3376 T. S. HORN. *Improvements in miners' safety lamps.* Dated November 28, 1867.

Here the base of the lamp forms the receptacle for the oil, having a tube in the centre for the insertion of the wick or lamp cotton, and for feeding or supplying the lamp with oil. Above this receptacle, and permanently attached to it, there is an air chamber perforated round the circumference for the admission of air horizontally at a point below the point of combustion. The top plate of this air chamber is also perforated with very fine holes for the admission of the air to a combustion chamber which surrounds the wick, and is formed of metal of a dome or other shape, having an aperture at the summit through which the wick can pass. This metal dome is fitted by a bayonet joint, screw, or other means into a metal ring or flange, which flange has formed on its outer or upper surface an annular groove for the reception of a glass chimney which is cemented therein. By the use of the dome the air for supporting combustion passing through the air chamber from below impinges on the flame at the point of combustion, rendering such combustion more complete, and therefore affording increased light. The dome also acts as an extinguisher should the lamp be either overturned by accident or otherwise, the light in that case immediately dying out. The products of combustion pass up the glass chimney through a contracted aperture in a metal cone fitted thereon, and becomes diffused by escaping through small perforations in a copper cap fitting on the glass chimney.—Patent abandoned.

3377 J. H. JOHNSON. *An improved hollow brick or block to be used for the floors, ceilings, and other parts of buildings, and apparatus for moulding or manufacturing the same.* (A communication.) Dated November 28, 1867.

According to this invention it is proposed to construct, in suitable moulds, hollow bricks or tiles of plaster cement, or other suitable material, of a square, rectangular, or other form. These blocks are perfectly closed up on all sides, although made cellular or hollow internally; consequently, the plaster employed in setting them in their place between the joints cannot possibly obtain access to the interior of the blocks. Ribs or projections are moulded along the several sides or edges of these closed hollow blocks, in order to afford a better hold to the plaster or cement, which is introduced between them when setting the same, and the top and bottom faces of the blocks are roughened or made uneven to form a key or holding surface for the adhesion of the coating or plaster employed in furnishing the floor or ceiling.—Patent abandoned.

3378 J. M. NAPIER. *Improvements in vessels and apparatus for the preserving and more convenient use of unguents.* Dated November 28, 1867.

The patentee claims arranging vessels, for the preserving and more convenient use of unguents, with a piston-like cover, and with an orifice with a wiping surface around it. He also claims combining with such vessels, either permanently or when required for use, apparatus by means of which the piston-like cover may be progressively forced into such vessel, so as to expel the unguent through the orifice as it is required for use. He also claims the general arrangements of the vessels and apparatus, substantially as described.—Patent completed.

3379 E. WOOD. *Certain improvements in steam engines.* Dated November 28, 1867.

The patentee claims, first, the combination of a gridiron slide valve with an arrangement of mechanism called or used as a "trippet motion," the valve moving in a direction at right angles to the length of the steam cylinder. Second, the novel arrangement and construction of "gridiron valves" and cylinders for steam engines wherein part of the cylinder constitutes the seating or surface upon which the valves work or slide, by which means movable valve seatings and side pipes are dispensed with. Third, the combination of a gridiron slide valve with the well-known mechanical contrivance called a "dash pot," whether the parts so combined be used with or without a "trippet motion." Last, the addition and combination of steam or air buffers to pistons for closing valves, the said buffers being of greater area than the pistons used for such purpose, as described, set forth, and fully illustrated in the drawings.—Patent completed.

3380 J. R. PRATT. *Improvements in the construction of articles of earthenware.* Dated November 28, 1867.

This invention relates to an improved method of joining together the separate parts of articles of earthenware by forming on them male and female screw threads while the clay or plastic material from which the articles are made is in a soft state.—Patent completed.

3381 E. H. BENTALL. *Improvements in the manufacture of nuts and bolts.* Dated November 28, 1867.

This invention is not described apart from the drawings. —Patent completed.

3382 J. SCHOLEFIELD. *Improvements in cases or covers for umbrellas, and in the umbrellas to which such cases or covers are to be applied.* Dated November 28, 1867.

The patentee claims, first, the manufacture of cases or covers for umbrellas of curved india rubber, or other suitable material possessing sufficient elasticity, the cases being normally considerably shorter than the umbrellas to which they are to be applied, so that when applied they compress the umbrellas into a small compass, as described with reference to the drawings. Second, providing the handles of umbrellas with studs or appliances, substantially as described.—Patent completed.

3383 J. R. TOWERS. *Improvements in bedsteads, which improvements are also applicable to other purposes.* Dated November 28, 1867.

This invention relates to an improvement in that part of a bedstead by which the sides and ends are secured to the posts, and consist in mortising or recessing the ends of the side and end bars into the posts, there being no projecting parts thereon to be knocked off or otherwise damaged. The side bar the inventor provides with a recess at its end through which the end bar passes at right angles when adjusted in place in the post. A screw bolt passes through both these ends, firmly securing them in the post in which a screw thread is tapped for securing the bolt passing up therein. The post he forms in two parts, the screw bolt above mentioned forming the end of the lower part or leg, which passes up through the ends of the bars, as before described, into the upper part of the post.—Patent abandoned.

3384 J. BAYLIS. *Panoline dye.* Dated November 28, 1867.

This invention consists of a compound chemical substance possessing the property of imparting a disposition to receive a fast colour of equal shade simultaneously upon animal and vegetable fibres; thus a mixed textile fabric of cotton, wool, or silk, or any of them, may be dyed into various colours by one process, instead of a separate process for each fibre, as in the practice generally in use. The inventor produces this substance by the chemical reduction of cuperiferous arsenic.—Patent abandoned.

3385 W. R. LAKE. *An improved apparatus for boiling and washing textile fabrics and fibres.* (A communication.) Dated November 29, 1867.

This invention relates to means for producing the circulation of water or other cleansing liquid or steam through a boiler for washing textile fabrics and fibres, and for other like purposes, and consists, chiefly, in dividing the said boiler into an upper and lower chamber, separated by a perforated partition, and communicating with each other by means of tubes which extend from the lower chamber nearly to the top of the upper chamber in which the articles to be washed are placed. The boiler must be closed and strong enough to bear a slight pressure of steam, which causes the circulation of the liquid or vapour through the tubes and chambers.—Patent abandoned.

3386 J. B. JORDAN and J. DARLINGTON. *Improvements in machinery for boring rocks, and in apparatus for driving, rock boring, tunnelling, coal cutting, and other machinery employed in mines, collieries, and quarries.* Dated November 29, 1867.

This invention is not fully described apart from the drawings.—Patent completed.

3387 J. FRASER and G. DUNCAN. *Improved combined machinery for printing.* Dated November 29, 1867.

The patentee claims combining or arranging printing and consecutive numbering machines whereby to imprint at the same time, or in a conjoined operation, on continuous webs or rolls, or on a continuous supply of paper, the desired letterpress and consecutive numbers for the purpose set forth.—Patent completed.

3388 T. ROSE and R. E. GIBSON. *An improved mode of treating cotton seed to obtain oil therefrom, and in machinery employed therein.* Dated November 29, 1867.

The patentees claim, first, subjecting cotton seed to a rubbing, grinding, stamping, or pulverizing action, and thereafter sifting out or separating the meal, such meal being the product employed to yield oil, substantially as described. Second, the employment of rotating rolls with serrated surfaces operating substantially in the manner and for the purpose set forth. Third, in combination with the said rotating serrated rolls the vibrating screens operating substantially in the manner and for the purpose set forth. Fourth, the employment of rotating arms or beaters in a perforated cylinder for the purpose set forth.—Patent completed.

3389 C. ALBISSER. *Improvements in the preparation of sulphate of magnesia, applicable to the treatment of the crude potash, salts of Stassfurt, and the refuse from the manufacture of chloride of potassium.* (A communication.) Dated November 29, 1867.

A patent, dated the 23rd of September last, was granted to A. Ziegele for the manufacture of Epsom salts from these crude salts. The kiesecrit which the crude salts contain may, however, be separated and manufactured into a form in which it is commercially useful without hydrating the sulphate of magnesia, so as to bring it to the state in which it is commonly known as Epsom salts. The preparation of such sulphate of magnesia from crude salts containing kiesecrit is the object of the present invention. —Patent completed.

3390 M. F. MAURY. *An improved mode for protecting submarine cables when placed on board ship from injury by design or from damage by accident, and for facilitating the paying of them out.* Dated November 29, 1867.

Here the cable is not furnished with the usual outside covering of wire, but it is insulated in the usual manner. It is packed in hogsheads or casks which are filled with water, both ends of the cable being left outside the hogsheads or casks for the purpose of testing, &c. The inventor states that, as there is no running water at the bottom of deep seas, a cable which is heavy enough to sink will be found sufficiently strong. By dispensing with the outside covering of wire and non-insulating coating the cost of the cable is lessened, and the laying thereof facilitated.—Patent abandoned.

3391 H. S. COWAN. *Improvements in apparatus for signalling at sea.* Dated November 29, 1867.

The object of this invention is to enable one vessel to indicate to others the exact course she is steering, and the invention consists, mainly, in the use of two lights or lamps of different colours, the relative position of one of which as regards the other indicates the course the vessel is steering.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated February 1, 1868.

356 J. Jameson, Catherine-terrace, Gateshead, engineer. Improvements in the preparation of postage and other stamps, and in the obliteration of the same.

Dated February 8, 1868.

431 W. Richardson, Oldham, mechanical engineer. Improvements in machinery or apparatus for the manufacture of combs to be used in carding engines as doffer or other such combs, or in wool burring, cotton cleaning, or other machines used in the treatment of fibrous materials in which combs of like character are required.

Dated February 25, 1868.

636 R. Kerr, Paisley, Renfrewshire, manufacturer. Improvements in the method of, and apparatus for, heating conservatories and other similar houses or structures.

Dated March 18, 1868.

921 C. J. Appleby, Emerson-street, Southwark, Surrey, and I. Riley, Freeling Cottage, Freeling-street, Caledonian-road, Middlesex, engineers. Improvements in cranes or other machinery for lifting, lowering, and hauling by means of steam, gas, heated air, or other fluid pressure, and in the boilers or furnaces for generating the power for the same, such improvements being applicable in part for other purposes.

Dated April 21, 1868.

1298 S. Dreyfous, Paris. An improved apparatus for removing the cotton from cotton pods. (A communication.)

Dated May 1, 1868.

1426 A. Munro, Arbroath, Forfarshire. Improvements in machinery, tools, and tool holders to be used for cutting stone, slate, marble, and other materials.

1430 P. Marlin and A. Tack, civil engineers, Brussels, Belgium. An improved process for transforming hydrocarbon oils into gas for illuminating and heating purposes.

Dated May 5, 1868.

1470 D. R. Macgregor and P. Taysen, merchants, Leith, Edinburgh. Improvements in the manufacture of paint for the protection of iron and other metals from the destructive influence of sea water, and for the prevention of fouling. (A communication.)

Dated May 6, 1868.

1481 J. Young, Aspull, Lancashire. Certain improvements in the construction of ovens to be employed in the manufacture of fuel termed coke, oil, and gas.

Dated May 7, 1868.

1497 B. Pickering, Kingston-upon-Hull, seed crusher. Improvements in apparatus used in expressing oils and fatty matters from seeds and from substances in which such matters are contained.

Dated May 8, 1868.

1513 C. E. Brooman, Fleet-street, City, patent agent. Improvements in preparing zirconia, and the employment of the same to develope the light of oxyhydrogen flame. (A communication.)

1515 W. Seck, Richmond-terrace, Clapham-road, Surrey, mechanical engineer. Improvements in machinery or apparatus for hulling and winnowing grain.

Dated May 9, 1868.

1522 S. Moulton, Bradford, Wiltshire, india-rubber manufacturer. Improvements in the treatment of vulcanized or cured india-rubber for obtaining a substance of a mossy nature, suitable for printers' inking rollers, cushions, and other articles.

1524 A. M. Clark, Chancery-lane. Improvements in breech-loading firearms. (A communication.)

1529 J. H. W. Biggs, Manchester. Improvements in apparatus for selecting warp threads, and for drawing them through the eyes of harness and through reeds.

Dated May 13, 1868.

1551 J. Slater, engineer, Catherine-terrace, Lansdowne-road, S.W., Surrey. An improved method of breaking up macadamized roads and other surfaces, and apparatus or machinery therefor.

Dated May 14, 1868.

1579 J. E. Piper, Wilson-street, Finsbury, Middlesex. A new improved oil for lubricating machinery.

Dated May 16, 1868.

1604 J. G. Tongue, Southampton-buildings, Chancery-lane. Improvements in apparatus for sewing or stitching together the numbers or separate parts of a volume in the operation of book binding. (A communication.)

1605 W. Rule, jun., Dolcoath Mine, Camborne, Cornwall, tin dresser. An improved machine or apparatus for dressing metallic ores.

1610 A. M. Clark, Chancery-lane. Improvements in lamps for burning mineral oils and essences. (A communication.)

1618 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in apparatus employed in the manufacture of iron and steel. (A communication.)

Dated May 18, 1868.

1622 W. Manwaring, Britannia Works, Banbury, Oxfordshire, engineer. Improvements in lawn mowing machines.

1624 W. Needham and J. Kite, Vauxhall, Surrey, engineers. Improvements in preparing filtering surfaces for the depuration of fluids.

1625 L. Goldstein, Bradford, Yorkshire, merchant. Improvements in umbrella and parasol cloths.

1626 J. F. Spencer, Sunderland, Durham. Improvements in working the valves of steam and other engines.

1628 J. Mitchell, Sheffield, spring manufacturer. Improvements in railway and other carriage springs, and in the machinery or apparatus for manufacturing the same.

1629 J. Grantham, King's Arms-yard, City, civil engineer. Improvements in the construction of iron and steel-built ships, and in rudders.

Dated April 19, 1868.

1630 E. P. H. Vaughan, Chancery-lane. Improvements in the preparation of anhydrous chlorides by means of sulphides or their elements. (A communication.)

1631 E. P. H. Vaughan, Chancery-lane. Improvements in the construction of pipes for smoking. (A communication.)

Digitized by Google

1632 R. Pearce, Swansea, Glamorganshire. Improvements in the separation of copper and other metals from silver.

1633 J. Flachfeld, Basinghall-street, City, merchant. A new manufacture of cases for pipes and tubes used in smoking. (A communication.)

1635 J. Steel, Glasgow, brewer. Improvements in cask washing apparatus.

1636 J. Elce, Manchester. Improvements in temples employed in looms for weaving.

1637 D. A. Cooper, Worcestershire, goldsmith. Improvements in solitaires or fastenings for gloves and other articles of dress.

1638 J. Pollock, Birmingham, accountant clerk. Improvements in instruments or apparatus for drawing corks from bottles.

1639 T. Griffen, Guilford-street, Russell-square, Middlesex. Improved apparatus for bleaching and cleansing fabrics.

Dated May 20, 1868.

1640 W. Jones, engineer, and J. Hetherington, machinist, Manchester. Improvements in machinery for stretching woven fabrics.

1641 H. H. Johnson, Cannon-street, City, wine merchant. An improved mode of advertising in railway tunnels and cuttings.

1642 J. Kennett, Alma-place, Eastbourne, Sussex. An improved method of ventilating sewers.

1643 J. Fry, perambulator manufacturer, Stephen-street, Lisson-grove, Marylebone, Middlesex. Improving the construction of folding perambulators in order to contract them into a smaller compass.

1644 R. Froehlich, South-grove East, Mildmay Park, Middlesex. Improvements in means or apparatus for opening sardine and other sheet metal cases or receptacles, which improvements are also applicable to cutting sheet metals and other materials. (A communication.)

1645 C. L. Tavernon, Boulevart de Strasbourg, Paris, practical engineer, and J. Moret, Sevres, near Paris, merchant. An improved lift and force double-action pump, giving a continuous and regular supply of liquid.

1647 F. D. Nuttall, St. Helen's, Lancashire. Improvements in reverberatory furnaces for wasting and smelting purposes.

1648 J. B. Whitely, Prospect Iron Works, Lockwood, near Huddersfield. Improvements in machinery for stretching, drying, and producing the elastic finish on woven fabrics.

1649 A. Bell, Alfred-road, Middlesex, engineer. Improvements in the valves of steam engines.

1650 W. F. Batho, Birmingham. Improvements in machinery for planing or shaping metals, wood, or other materials.

1651 H. D. Hoskold, Cinderford, Gloucestershire, J. Davis, St. Whites, Gloucestershire, mining engineers, and G. P. Wheeler, Abinghall, Gloucestershire, engineer. Improvements in the manufacture of artificial fuel.

1652 Z. Poirier, The Grove, South Lambeth, Surrey, merchant. A new or improved safety stopper for bottles and other vessels.

1653 A. Leslie, Turriff, Aberdeen, bank agent. Improvements in machinery or apparatus for steam cultivation.

1654 D. Jones, Cambridge Heath, Hackney-road, and J. Jackson, Ann-street, Ratcliffe, Middlesex. Improvements in apparatus for imparting heat to the feet and body whilst travelling or otherwise.

1655 W. Tijou, Great George-street, Westminster, engineer. Improvements in steam pumps.

1656 C. R. Havell, Reading, Berkshire, artist. Improvements in the means or apparatus for heating water for baths, and other purposes.

1657 W. England, Bristol, commercial traveller. Improved apparatus for measuring liquids.

1658 A. V. Newton, Chancery-lane. Improvements in sewing machines. (A communication.)

1659 W. Inglis, Manchester, engineer. Improvements in steam engines and boilers.

1660 W. Sim, Glasgow, contractor. Improvements in arrangements or apparatus for watering and cleansing streets and roads, and in the application of apparatus for removing snow, and to other purposes.

1661 G. T. Bousfield, Loughborough Park, Brixton, Surrey. Improvements in power looms. (A communication.)

1662 C. Barnard, Norfolk Iron Works, Norwich. Improvements in chairs and other articles of furniture to sit or recline upon.

1663 J. Convers, Rue de la Paix, Paris, naval engineer. Improvements in cranks and crank shafts and axles.

1664 W. R. Lake, Southampton-buildings, Chancery-lane. An improved device for marking and creasing tucks in cloth or other material upon a sewing machine. A communication.)

Dated May 21, 1868.

1667 W. Palliser, Army and Navy Club, Pall Mall, major unattached, and F. J. Bolton, Rochester, Kent, captain in the army. Improvements in ordnance, and in wads to be used therewith.

1668 E. A. Chameroy, Rue Faubourg St. Martin, Paris, manufacturer. An improved liquid or gas meter.

1669 W. Hadfield, Manchester, manufacturer. Certain improvements in looms for weaving.

1670 J. E. Poynter, Glasgow, manufacturing chemist. Improvements in the manufacture of soap.

1671 J. Booth, Birmingham, printer and stationer. Improvements in fastenings for bags of paper, linen, or other flexible materials.

1672 J. Crofts, R. Dawson, and J. King, Hunslet-lane, Leeds. Improvements in means or apparatus for combing wool or other fibres.

1673 E. E. Allen, Parliament-street, Westminster. Improvements in the mode of packing, covering, or making up materials wound upon spools, or in the form of bundles or skeins.

1675 T. G. Messenger, Loughborough, Leicestershire, hydraulic engineer. Improvements in fire engines or double-action pumps.

1677 R. Fryer, Manchester, railway inspector, and J. Fryer, St. John's Wood, London. Improvements in machinery or apparatus for tilling land.

1678 J. Starley, Coventry, Warwickshire. Improvements in sewing machinery.

1679 J. R. Batty, Leeds, machinist. Improvements in saddles for frames used in the spinning of flax or other fibrous substances.

1681 H. Hall and J. A. Mason, Burton-on-Trent. Improvements in apparatus for propelling vessels.

1682 F. E. B. Beaumont, The Garrick Club, London, and C. J. Appleby, engineer, Emerson-street, Southwark. Improvements in apparatus for drilling rock and stone for blasting and other purposes.

1683 J. W. Whittaker, Carlisle Villa, Great Lever, near Bolton-le-Moors, Lancashire, cotton spinner. Improvements in carding engines.

1684 R. Rayner, Lower Clapton, Middlesex. Improvements in frictional gearing. (A communication.)

Dated May 22, 1868.

1686 C. Fu-not, Curighem-lez-Bruxelles, Belgium, manufacturer. Improvements in central-fire cartridges.

1687 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in the means and apparatus for drawing cop and other threads through shuttle holes and eyes. (A communication.)

1688 C. Mole, Farringdon-road, City, boot maker. Improvements in the manufacture of boots.

1689 W. E. Newton, Chancery-lane. Improvements in grate bars. (A communication.)

1691 A. M. Clark, Chancery-lane. Improvements in rotary steam engines. (A communication.)

1694 R. K. Bowley, Rockhills, Upper Sydenham, Kent. Improvements in the construction and arrangement of floral devices, and in the apparatus employed therein. (A communication.)

Dated May 23, 1868.

1697 J. Higgins, Salford, Lancashire, machine maker. Improvements in machinery for spinning and doubling cotton and other fibrous materials.

1698 J. Fletcher, Bow, Middlesex, engineer. Improvements in revolving retorts for the manufacture and reburning of animal charcoal.

1699 E. W. de Rusett, Lewisham, Kent, civil engineer. Improvements in engines worked by steam or other motive fluid, specially applicable to steam pumps.

1700 T. Ashford, Birmingham, nail cutter. Improvements in machinery for the manufacture of gas tube hooks or fastenings.

1701 W. Seck, Richmond-terrace, Clapham-road, Surrey, engineer. Improvements in kilns or apparatus applicable to the drying or treating of grain for the manufacture of malt.

1703 F. Wirth, Frankfort-on-the-Maine, Germany. An improved apparatus for causing the circulation of water in steam boilers. (A communication.)

Dated May 25, 1868.

1705 T. J. Baker, Farndon, near Newark, Nottinghamshire, miller. Improvements in the manufacture of wheat and other grain into flour, and in the machinery connected therewith, part of which improvements are applicable to grinding gypsum and similar substances.

1707 E. Hunt, Glasgow. Improvements in obtaining motive power, and in apparatus therefor.

1709 P. Cameron, Glasgow. Improvements in ships' compasses.

1711 S. A. Smith, Walton-le-Dale, Lancashire, cotton spinner. Certain improvements applicable to carding engines.

1715 W. H. Kent, St. George's-place, Knightsbridge, Middlesex. Improvements in machinery for fluting, crimping, and pulling fabrics. (A communication.)

1717 J. Scoffern, New North-street, Finsbury, Middlesex, M. B. Improvements in treating paper and woven fabrics to produce therefrom waterproof sheets and slabs.

1719 H. L. A. Lippens, Southampton-buildings, Chancery-lane. Improvements in looms for weaving.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated May 28, 1868.

1767 H. Haines, Southampton-buildings, Chancery-lane. Improvements in the manufacture of lead pipe and lead pipe lined or cased with tin or other metal. (A communication.)

Dated May 29, 1868.

1777 G. T. Bousfield, Loughborough Park, Brixton, Surrey. Improvements in plating spoons and other articles with a coating of metal. (A communication.)

Dated June 2, 1868.

1803 T. Christy, New York, U.S. Improvements in paper satining machines.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," June 9, 1868.

276 J. J. Hicks. Backs and handles for hand mirrors.

280 W. E. Newton. Machinery for grinding and polishing concave surfaces. (A communication.)

289 W. A. Gibbs. Mechanism for drying wheat in the sheaf.

290 W. H. Crispin. Anti-scorbutic biscuits.

297 J. Pearson and J. W. Young. Apparatus for purifying oils.

298 J. Brown. Machinery for cutting wood.

309 S. B. Ardrey and S. Beckett. Velocipedes.

310 W. Tasker. Machine for cleaning cotton. (A communication.)

314 C. Riley. Combined threshing machine frame.

317 W. E. Newton. Breech-loading firearms. (A communication.)

319 W. R. Lake. Furnaces for roasting ores. (A communication.)

324 M. A. Hamilton. Apparatus for cutting bread.

327 T. Rowan. Removing impurities from iron ores.

328 B. Hayne. Connecting beer engine pipes with their taps.

340 H. Chapman. Bolts and nuts.

341 J. Mitchell and G. T. Graham. Apparatus for cutting fabrics into lengths.

343 G. L. Scott. Apparatus for steering ships.

344 S. E. Howell. Suspension bridges.

346 J. Frame. Transmitting motive power.

348 G. Clarke. Fire-escapes.

349 G. Moulton. Pentograph engraving machines.

352 H. Aitken. Treating iron ores.

353 A. Clark and A. V. Winkle. Apparatus for manufacturing aerated waters. (Partly a communication.)

356 J. Jameson. Preparation of postage stamps.

361 M. A. Wilson. Spring mattresses.

366 C. Richardson. Looms for weaving.

367 W. R. Lake. Leggings. (A communication.)

374 J. Lewis and R. and E. Alston. Movable firebars.

382 T. Scott and R. Mowat. Lamps for burning paraffin oils.

394 W. E. Newton. Mowing and reaping machines. (A communication.)

395 W. E. Newton. Buttons. (A communication.)

398 J. Hay. Method of roughing horses.

408 G. F. Bradbury and T. Chadwick. Sewing machines. (A communication.)

410 C. Brakell. Apparatus for measuring fluids.

423 J. B. Wilson. Forging steel.

426 T. Walker. Construction of sewers.

427 P. Rothwell. Regulating valve for the delivery of specific quantities of gas.

465 A. Brin. Apparatus for generating and applying gas from air and hydrocarbon fluids.

494 W. R. Lake. Whip holder. (A communication.)

553 W. R. Lake. Process of seasoning wood. (A communication.)

611 W. E. Newton. Manufacture of illuminating gas (A communication.)

655 J. R. Cooper. Breech-loading firearms.

683 J. F. Low. Apparatus for preparing jute.

691 H. B. Wilder. Magnetic electric telegraphic apparatus.

855 B. Britten. Manufacture of manure.

927 S. Wenkheim. Method of combining a shirt and waistcoat, or portions thereof, so as to be worn either as a waistcoat and shirt, or as a shirt only.

1265 G. Lister. Machinery for feeding slivers of wool to carding engines.

1276 T. A. Warrington. Candlesticks.

1297 L. Bing. Apparatus for ascertaining the actinic power of light.

1363 R. Cocker. Purifying and preserving wood. (A communication.)

1481 J. Young. Construction of ovens.

1541 S. Buxton. Pens.

1552 S. B. Boulton. Loading timber in timber yards.

1613 W. Allday. Forge bellows.

1614 A. Parkes. Manufacture of parkesine.

1615 G. Price. Pianos.

1619 M. A. Hamilton. Churns.

1622 W. Manwaring. Lawn mowing machines.

1721 W. R. Lake. Horses' harness. (A communication.)

1767 H. Haines. Manufacture of lead pipe. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed June 5, 1868.

3472 J. W. Kenyon and R. A. Armitstead	3499 L. Rose
3477 F. Roper	3506 W. H. Barlow
3483 R. B. Jones and W. Powell	3519 J. M. Napier
3484 J. B. Morrison	3535 E. R. Sintzenich
3485 O. Barrett and H. Leggott	3540 J. Robinson
3486 J. Blakey and H. B. Fox	3550 J. G. Settle
3492 R. Warry	3571 J., J., and J. Booth
3497 W. Clapperton	3640 J. Rowe
	8 H. Milward
	158 R. Heathfield
	886 H. A. Bonneville

Sealed June 9, 1868.

3503 W. B. Leachman	3551 T. Pebardy
3510 J. W. Burton	3560 R. Tinkler

The only **SILVER MEDAL** awarded at the **PARIS EXHIBITION** of 1867 for **WOOD-WORKING MACHINERY** in the British Section, and the
PRIZE MEDAL of the **INTERNATIONAL EXHIBITION, 1862,**

WERE AWARDED TO

S. WORSSAM & CO.,

FOR

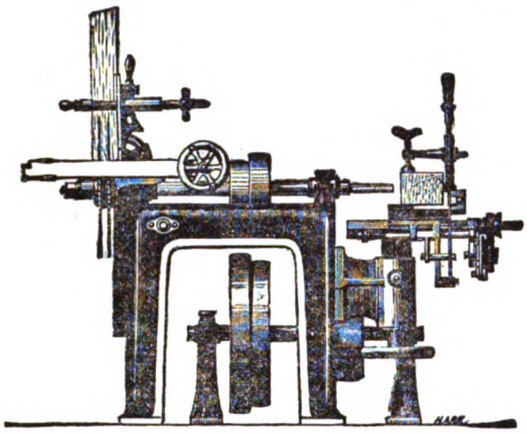
"A SUPERIOR COLLECTION OF WOOD-WORKING MACHINERY,"

SAW-MILL ENGINEERS,

AND MAKERS OF

MACHINES OF ALL KINDS FOR WORKING IN WOOD,

KING'S ROAD, CHELSEA, LONDON.



THE "GENERAL JOINER."

THIS exceedingly useful machine was invented by S. WORSSAM and CO., and performs nearly all the various kinds of work usually done by hand in a Joiner's Shop, such as Sawing, Planing, and Thicknessing, Mortising, Tenoning, Cross-Cutting, and Squaring-off, Grooving, Tonguing, Rabbetting, Moulding, Beading, Chamfering, Boring, Wedge-Cutting, and many other operations. With a little practice any joiner can work it, and with the aid of a man and boy it will do the work of at least fifteen men.

CAUTION.—The great reputation which the "General Joiner" now enjoys has caused may spurious imitations of it to be made by other Manufacturers, all of whom, however, have overlooked most of the details in its construction which are essential to its success. S. WORSSAM and CO., therefore, strongly advise those who think of purchasing a "General Joiner," to see the Original Machine at work before purchasing any of the spurious copies.

SAMUEL WORSSAM & Co.'s IMPROVED SAW-SHARPENING MACHINE.

This Machine Gullets, Tops, and Bevels the teeth of Circular and Frame Saws, so as not to require touching by a file. It is easily adjusted so as to produce any required form of tooth, and effects a saving equal to 500 per cent. in wages and the total cost of the saw files used when sharpening by hand.

S. WORSSAM & CO.,

Beg to call particular attention to their

Improved Machines for Sawing, Planing, and Moulding.
Improved Labour-saving Machines for Joiners' Work.
Improved Machines for Railway Carriage and Waggon Building.
Machines Specially Adapted for Engineers' Pattern Shops.
Machines for Cabinet Makers.
Machines for Pianoforte Makers.
Machines for Agricultural Machine Makers.
Machines for Sawing and Planing Stone and Marble.

SAMUEL WORSSAM and Co. furnish plans and estimates of complete sets of Wood-Working Machines for Saw-mills, or for Builders, Contractors, or Railway Carriage Builders' Works, Arsenals, Dockyards, &c., and contract to supply, fit up, and start the whole, including Machines, Engines, Boilers, Shafting, Bands, Saws, Cutters, &c., for a certain fixed sum, including all Items usually charged as extras.

Illustrated Descriptive Catalogues, with full particulars of the above machines, sent free on application at the Works,

KING'S ROAD, CHELSEA, LONDON.

PERIN'S PATENT FRENCH BAND SAW BLADES.

SAMUEL WORSSAM AND CO.,

Having purchased of M. Perin, of Paris, the sole right to import and sell his Band Saw Blades throughout the United Kingdom, beg to announce that they are now in a position to supply these saws from 1-16th in. to 8in. in width, and up to 50ft. in length.

The vast superiority of PERIN'S BAND SAWS over any others in point of finish, toughness, durability, and evenness of temper, is now everywhere admitted.

S. WORSSAM & CO. keep a large stock of all sizes up to 2in. wide, from which they can supply orders to any part of the United Kingdom within an hours' notice.

FOR PRICE LISTS, APPLY TO

SAMUEL WORSSAM & CO.,

SAW-MILL ENGINEERS,

No. 304, KING'S ROAD, CHELSEA, S.W. A 43

WOOD BROTHERS'

PATENT OBLIQUE TRANSVERSE TUBES

For the Flues of Cornish Steam Boilers.

THESE Tubes are exceedingly simple in construction and application, and very durable. They give a greater amount of heating surface than any other transverse tube that can be put in a flue of the same piameter, consequently will generate more steam with greater economy of fuel, and they can be repaired or replaced much more readily than any others.

As these Tubes are put in obliquely, and at a proper inclination, having the flanches at both ends inside the flue, they may be put in or taken out of their places through the flue without passing inside the boiler at all, thus giving the opportunity of applying them to boilers already in use without disturbing them or taking out the flues, whatever be the relative dimensions of the shell and flue.

FOR PRICES, AND A LITHOGRAPH OF THE BOILERS, APPLY TO

WOOD BROTHERS, DON BOILER WORKS, SHEFFIELD. B 1

DINNEFORD'S FLUID MAGNESIA.—The Medical Profession for thirty years have approved of this pure Solution of Magnesia as the best remedy for Acidity of the Stomach, Heartburn, Headache, Gout, and Indigestion: and as the best mild aperient for delicate constitutions, especially adapted for Ladies, Children, and Infants.

DINNEFORD AND Co., CHEMISTS,
172, New Bond-street, London,
And of all other chemists throughout the world. A 59

THE BEST REMEDY FOR INDIGESTION.

NORTON'S CAMOMILE PILLS are confidently recommended as a simple but certain remedy for Indigestion. They act as a powerful tonic and gentle aperient, are mild in their operation; safe under any circumstances; and thousands of persons can now bear testimony to the benefits to be derived from their use.

Sold in bottles at 1s. 1½d., 2s. 9d., and 11s. each, in every town in the Kingdom.

CAUTION!—Be sure to ask for "NORTON'S PILLS," and do not be persuaded to purchase the various imitations. A 54

BILIOUS and LIVER COMPLAINTS

Indigestion, Sick Headache, Loss of Appetite, Drowsiness, Giddiness, Spasms, and all Disorders of the Stomach and Bowels, are quickly removed by that well-known remedy, FRAMPTON'S PILL OF HEALTH. They unite the recommendation of a mild operation with the most successful effect; and where an aperient is required, nothing can be better adapted.

Sold by all Medicine Vendors, at 1s. 1½d. and 2s. 9d. per box or obtained through any Chemist. A 4

MECHANICS' MAGAZINE.

LONDON: FRIDAY, JUNE 19, 1868.

RECENT GUNNERY EXPERIMENTS AT SHOEBURYNESS.

DURING the past few days Shoeburyness has presented unusual attractions to artillerists and military engineers, owing to the trials of iron structures, applicable to land fortifications. The experiments commenced on Tuesday last, and were under the direction of the Ordnance Select Committee and Associated Members. The executive duties devolved upon Colonel F. Eardley Wilmot, R.A., commandant of Shoeburyness, who was assisted by Captain Alderson, R.A., and an excellent staff of working officers. The first day's work consisted principally in a trial of the Plymouth shield, against which eight rounds were fired, five of which were directed against a point to the right of the porthole, which had been strengthened by a 5-inch plate in place of some of the 5-inch bars. The other three shots were fired at the built-up side of the shield. The gun used upon the occasion was a 23-ton 12-inch rifled gun, which was fired with battering charges of 76lb. of powder and 600lb. Palliser projectiles. The heavy charges were determined upon in order to test the strength of the shield with the full power of the gun. Two rounds were also fired from the American 15-inch gun. The guns were placed at a range of 200yds. from the targets. The first shot struck the armour-plated target about 3ft. from the ground, and 15in. from the right-hand edge, and tore open the strip of iron outside the shot. The shot penetrated to the depth of about a foot, and then broke up, a bolt being driven inwards, and the inside plates being slightly bulged. A shell with a bursting charge of 14½lb. of powder was next fired, and struck just above the port. The shell did not penetrate the target very deeply, bursting in the rear. Its effect was to break the horizontal iron plank over the porthole in two, on the right-hand side of the port, and to thrust it backwards, the damage showing only at the back of the shield. The third shot was fired from the Rodman 15-inch gun, with a powder charge of 83½lb. of powder, equal to 100lb. of American powder, and a 450lb. spherical projectile. This shot struck not far from the shot of the first round. It cracked the front plate, started another bolt, and bent the inside layer of iron, doing, however, but little damage. The shot, which was of American make, and appeared to be of excellent iron, rebounded, and fell, much flattened, a few feet in front of the target. As this shot was a graze, a second shot was fired from the same gun, striking at a point 5ft. from the ground and 18in. from the left edge. The result was an indent about 9in. in depth, the plate being cracked through to the edge and the right-hand corner, which had been previously struck, being knocked off by the shock. The inner planks near the porthole were distorted, and an upright standard was slightly bent. The shot struck on a spot where the plates were supported by one of these standards, and which was, therefore, a strong place. The effect, however, of both these rounds appeared very small for the large charge of powder, and gave but an indifferent opinion of the power of the great American weapon as compared with that of our own rifled guns.

The fifth shot was fired at the target from the 12-inch rifled gun, penetrating about 13in., breaking a bolt, and doing considerable damage at the back of the target. It pushed out the middle layer of iron, and broke one of the horizontal planks of the internal layer, a piece of which, weighing between 200lb. and 300lb., was violently projected about 100ft. to the rear of the target. The projection to the rear of this large mass of iron would have been a serious thing in actual warfare, although this is provided against by a thick rope mantlet hung immediately in the rear of the shield. The sixth round was directed against the weaker part of the target, which represented the actual construction of the Plymouth fort, and was 15in. thick. This and the two following shots were intended to strike a part between the upright standards, where the plates were unbacked. This, however, was not accomplished, each shot striking a place immediately in front of the upright standards. This was perhaps to be accounted for by the circumstance that the charges were very different from those ordinarily used, and the calculations made for laying the guns may, therefore, have been affected. The sixth round was a solid shot, which penetrated about 10in., breaking two bolts, and causing a bulge in both the back plates and the standards. The seventh round was a shell, which burst outside, and did little further mischief. The eighth and last round for the day was a solid shot, which caused a considerable bulge in the rear of the shield, which opened with a radiating crack, the standards also being much bent. An inspection after the firing showed that although the Plymouth shield had received eight rounds from the largest guns with full battering charges, it had stood very well, although, of course, it showed signs of having been punished.

The experiments on Tuesday concluded with a shot from the large rifled gun at each of two single unbacked 15-inch plates. The first of these was a rolled plate 13ft. 6in. long, 3ft. 5in. wide, and 15in. thick, prepared by John Brown and Co. It was simply resting against standards representing those of the Plymouth target. The second plate was of hammered iron, 9ft. long, 4ft. 6in. wide, and 15in. thick, and was supplied by the Thames Iron Company at their own expense. The shot fired at Sir John Brown's plate was aimed centrally between the two supports, and it struck the middle of the plate fairly. The point penetrated about 12in. into the solid metal, throwing up a bulge of about 3in. at the back, with a slight radiating crack. The shot fired at the Thames Iron Company's plate was a failure, as it struck the edge, carrying away a large piece of iron. The object of firing at these plates was to compare the results, not only of one with the other, but of the solid 15-inch plates as against a shield made up of three 5-inch layers. This object, however, so far, was frustrated by the shield not having been struck upon an unsupported part.

On Wednesday the experiments commenced by another attack upon the Plymouth shield, the Rodman gun having first fire. The powder charge and the projectile were similar to those on the previous day. The shot was directed against the built-up portion of the shield, and struck in front of an upright standard, making an indent of 7in., but doing very little further damage behind, although it hit a place which had been much punished already. The rifled gun then put in a shot with a 76lb. charge, which struck under the left-hand corner of the porthole. The result was a penetration of about a foot and a considerable cracking of the plate in front. In the rear much damage was visible, the inner layer of 5in. iron being bulged out 8in., and torn open with wide rents, and three bolts were strained. The place where the shot struck had not previously been damaged, and, as it consisted of three wide plates superposed, it afforded a comparison with the effect of the same gun on the solid 15-inch plate, which was highly favourable to the latter, according to final results. A shell was next fired from the same gun at the built-up side of the shield, and struck fairly between the standards. It penetrated the plates and broke the inner plank, turning it against the pier behind. The shell exploded within the structure, the fragments mixing with pieces of the plate. The 18-ton 10-inch gun was next tried with 60lb. of powder and a shell, the bursting charge of which was 10lb. It was aimed at the same part of the target as the previous shots, and struck between the standards about 2ft. to the left of the Rodman shot. It broke off the intervening piece of the front plate and passed into the shield, where it exploded. These two shots did considerable damage, but it is to be observed that the strength of the shield at this point had been much reduced by four previous shots.

The fifth round was fired from the same gun as the last one, and with the same weight of powder. The shell struck nearly under the centre of the port, penetrating 17in. and sticking in the plate, the bursting charge exploding outside. Not much damage was done in front, but in the rear a piece of the inner plate, about 2ft. 6in. long by 15in. wide, extending horizontally between this and a former shot, and weighing 5cwt. or 6cwt., was broken off and projected behind the rope mantlet, which had been placed in position and hung down 5ft. away, and which was struck by the piece of plate and proved its power to resist large fragments and to prevent them passing into the gun chamber. The fragment of iron did no material damage to the rope curtain, but rebounded from it, and fell on the ground near the place from which it had originally been detached. A fragment of the hind part of the shell entered the porthole, and also struck the mantlet, but did not pass through. The next round was a shell from the 10-inch gun, which was thrown by a charge to equal a striking force at 1,000 yards range. It was aimed at the curved top plate of the target, forming the bend over from the face to the concrete roof. It made a hole 2ft. 4in. in the head of the shell remaining in the concrete. This was followed by a shell from the 12-inch gun, with a powder charge to equal a striking force at a range of 1,000 yards. The shell struck the top corner of the structure and carried it away in one piece—4ft. 4in. by 3ft. 3in., and weighing 13cwt.—a distance of 147ft., with a large 3-inch bolt attached. All the strengthening rails, brackets, and other securing positions twisted violently, and the top of one 12-inch vertical support bent back 6in. A crack opened in the brickwork, into which the pier giving support at this end is built. This was the last shot fired at this shield on Wednesday, attention being afterwards turned to the 15-inch plates.

The second shot fired at John Brown and Co.'s plate was from the 10-inch gun, and it struck the plate 10in. from proper left edge, and 1ft. 10in. from top. It penetrated 10in., producing a bulge and a star crack in the rear, and a crack from the bottom of the plate extending through the shot-hole. The third round was a 10-inch shell, which made an indent 12·2in. The crack in the front, which was made the day previously, opened, whilst there were diagonal corresponding cracks in the rear. This plate, from the numerous cracks, appears to hold together by only about 6in. of metal, and yet, if properly secured in position, it would undoubtedly prove serviceable as a means of defence. The second shot fired againt the 15-inch hammered plate of the Thames Iron Company was from the 12-inch rifled gun, with a full charge. The shot struck 15in. from the top edge, and broke the plate completely in half, driving the two fragments, weighing about 5 tons each, 20ft. asunder. The fractured surface, which was oblique, and presented a sectional area of 10 square feet, showed a good quality of iron, but was full of large flaws, from imperfect welding. Here for the day the trials ended; they were resumed yesterday, and we shall report further upon them next week.

Digitized by Google

Let us now turn to the practical results of these interesting experiments so far as they have gone. They have certainly most effectually settled two questions of the highest importance in a national point of view. In the first place, they have conclusively shown that a single plate of 15in. in thickness is vastly superior in point of resistance to three plates of an average thickness of 5in. each—a point which we theoretically demonstrated long since. In the next place, they have established the fact that hammered plates of a given thickness are incomparably inferior to rolled plates of the same thickness—a fact we have always insisted upon, and which we thought required nothing more than common sense to perceive. As the case stands, we have the well-built Plymouth shield, partly constructed according to Colonel Inglis's design, and consisting of a front 5-inch plate backed by a row of vertical and another row of horizontal 5-inch bars, and partly strengthened by removing some of the bars and placing plates around the port. The original portion was pounded into fragments, whilst the strengthened part stood the test somewhat better, the penetration not being complete by 4in. or so. On the other hand, we have a single plate merely placed against a few 12-inch vertical supports and a few wooden stumps, and upon which the heaviest artillery is brought to bear at close range, the result being indents, cracks, and bulges, but no penetration. Taking into consideration the widely differing conditions under which the shield and the plate were tried, the latter has proved a triumphant success, upon which we congratulate Sir John Brown and his partners. Not the less signal is the victory the rolled plate has gained over the hammered one. It must be a satisfaction to all to have the question thus practically settled, as there are still some who fondly cling to their old but erroneous notions of the value of hammered plates. We think, however, that no one will be in a hurry ever again either to make or use hammered iron plates. The material may be of the best, but the weld can never be depended upon. Of course, with some people, overriding all other considerations, comes the question of cost, but here the 15-inch rolled plate will stand close scrutiny. If a reasonable quantity be required, taking into consideration the rapidity with which erection could proceed, the fewer number of bolts required, and other points of details, the 15-inch plate will be found to be as economical as the veriest grumbler could wish. But if there be any who are disposed to cavil at comparative cost, there are none who can question the fact that three shots have been fired from our heaviest guns at an unsecured 15-inch armour plate, and all that they did was simply to crack it. But then the plate was stamped "John Brown and Co."

IMPERIAL ESTABLISHMENTS ON THE LOIRE.—No. II.

THE action of sea water upon both cast and wrought iron is well known, and there is scarcely any available precaution against the corroding influence it possesses. For this reason many pieces of machinery exposed to its attacks are manufactured of bronze, as in the case of screws for steam vessels. At Indret the castings for some of these weigh 13 tons, and are of great purity and smoothness of surface, the latter feature being the result of a peculiar process adopted in the foundry, which consists in lining the inside of the mould with a description of slaty paste, susceptible of the highest state of polish. The whole of the foundry, forges, and other accessories are included in the western division of the establishment. In the eastern divison, most of the boiler work is carried on, and the adoption of a uniform type of steam generators for the Imperial navy has conduced considerably to render them easier of construction, and more economical in cost. Their size or volume, of course, varies in accordance with the engine power they are required to furnish, but the same form, general arrangement of parts, and disposition of details, are adhered to with undeviating fidelity. The plates are submitted to a strict examination, and undergo a heavy test, before being passed as fit for that duty, and any that are not up to the standard are rejected peremptorily. Their thickness varies from 0·4in. to 0·72in., and, previously to 1865, they were all made with wood fuel at the workshops of Guerigny.

It is unquestionable that at present engineers are not decided respecting the merits of steel. One thing, however, is very plain, that the exaggerated anticipations with regard to its enormous superiority over wrought iron have been effectually dispelled. Bridges of infinite span, and boilers of inexplosible strength, will not be constructed of it any more than of iron. Steel plates and steel bars are in a state of probation, and it will altogether depend upon their future method of manufacture whether they will ever emerge from that condition. A very interesting, although not conclusive, example, is to be found in the boilers of the "Cassabianca," which was paid off after a cruise of only two years. The sides and top of the firebox had been made of cast steel, and the whole portion underneath the bars, with the exception of the points covered by bolts, was found to be corroded as if by an acid. No wrought-iron boiler ever evinced so complete a deterioration in the same short space of time. One of the chief difficulties to be surmounted before steel can obtain that confidence which will ensure its general employment is the production of it of a constant quality. With the view of ascertaining its precise advantages, and particularly when contrasted with iron, the French government have ordered some crucial experiments to be carried out. Steel boilers, the plates of which have been obtained from various establishments, have been supplied to the "Bouvet" and "L'Aigle," while that of the "Hamelin" has been divided into two parts, one constructed of wrought iron, and the other of Jackson's steel, made by the Bessemer process, so that in the comparison the conditions of trial will be common to both. There is not such a wholesale economy, with respect to weight, in the substitution of steel for iron in boilers as might be at first expected. In the boiler of the "Hamelin," the thicknesses of the two metals were in the proportion of four to five, representing the relative resistances of the two metals. The firebox, the shell, and the angle irons, are alone capable of a reduction in weight; the tubes and other parts, either of cast or wrought iron, cannot be altered, and, therefore, their weight may be considered a constant. Selecting the boiler of the "Hamelin" as an example, which is provided with four furnaces and steam chest, and calling its total weight unity, we have the following proportions:—Weight of fireboxes = 0·19; shell = 0·29; angle irons = 0·12. The total equals 0·6; the constant weight being equal to 0·4. We thus see that the diminution of weight by the employment of steel in lieu of iron is enjoyed only by 0·6 of the entire weight of the boiler, and since the ratio is as 4 : 5, the saving effected is one-fifth or 0·12 of the gross weight. This theoretical calculation was confirmed by the actual weight of two boilers, one of steel and one of iron; the former weighed 27 tons, and the latter 32, an approximation in practice sufficiently close to demonstrate the truth of the theory. But granting that the absolute weight and strength are slightly in favour of steel, yet the manufacture and manipulation of the more modern material is attended with risks and difficulties from which its rival is altogether free. If the plates of the former are exposed to a sudden current of air whilst at a high temperature, they invariably become brittle, and remain so, even in spite of annealing. Frequently plates, completely finished and ready to be put together, fracture by falling down; at other times a blow from the riveting hammer will crack them, and occasionally they will split without any apparent cause whatever. When a boiler is once fairly started upon service, it ought not to be subjected to any violent shock or absolute blow, but still there is danger that the incessant variations of temperature may give rise to sudden concussions of dilatation and contraction sufficient to occasion cracks, or even fissures, in a metal so easily assailable by rapid alternations of heat and cold.

At the premises of Indret, the fireboxes, which are all of the same type, are usually made first, inasmuch as they serve to occupy the workmen when business is slack in other parts of the establishment. The plates are marked by templets, the rivet holes being designated by white paint, punched, bent hot in the rolls, or cold under the hammer, as required, care being taken in the latter instance to use wooden hammers, so as not to destroy the rim of the rivet holes. In putting a firebox together, the sides are first temporarily placed in position, and the top adjusted to them; the other portions are then attached, and the position of the connecting rivets being accurately determined, and the places for the holes marked, the box is dismounted, the holes pierced, and any trifling fitting done that may be required. The second trial generally finds everything correctly adjusted, the permanent riveting is effected, and the operation is completed. The shell presents but little difficulty, being composed of plain sheets, cut exactly to the required dimensions, and capable of being pierced for the rivet holes without previous trial. When finished, the machines and boilers are shipped on board transports, and conveyed down the Loire as far as Saint Nazaire. There they are transhipped on board Government vessels, which convey them to the ships for which they are intended. A few words concerning the management of the establishment will bring our article to a close. Similar to French, and, in fact, all continental workshops, the employés receive a far greater amount of care and attention than what is bestowed upon the same class of men in England. Twenty-five years of active service qualify for a retiring pension, which is in proportion to the rank and abilities of the recipient at the time of his retirement. One excellent rule is the separation of the apprentices, who are mere boys from fourteen to seventeen years of age, from the adults. This is an arrangement worthy of all praise, and ought to be universally adhered to. It is in vain to expect that our workmen will mend their language and manners, so long as the youth has for example and pattern those who are careless of self-improvement, who live only for the day, and but too often indulge in practices and habits that must have ruined many of their juniors before they were out of their time. The difference between our education and that of foreigners, and which is beginning to tell so heavily against us now, is that our apprentices are never taught, in the strict sense of the term. They learn by imitation, to a certain degree, and pick up the knowledge of their trade in a parrot-like, imperfect kind of manner, but there is no system, no principle of routine laid down for them, and therefore, as a rule, the best of them are only as good as their predecessors. Contrast this system—or, rather, this want of system—with that adopted at Indret. There the apprentices' workshop is a regular practical school. With the file, the hammer, or other implement in his hand, the lad carries out what his teacher has perhaps the day before orally explained to him. It not unfrequently occurs that private firms pay visits to these workshops for the express purpose of engaging the services of some of the most able and skilful of these youthful workmen.

Digitized by Google

Every year a selection of about thirty of the cleverest and most intelligent apprentices takes place, who are sent to a finishing school, as it might be termed, where they remain two years. They leave it, understanding how to read, write, calculate, and draw; possessing a thorough knowledge of mechanics, the theory of the steam engine, and of such other science as will be useful to them, and permit of their taking their place either as draughtsmen or superintendents in the establishment. Had we taken these precautions to ensure the prosperity of our workmen, we should have had fewer disputes, fewer strikes, and would not now be obliged to acknowledge that if we are not actually succumbing to, we are at least resisting with difficulty, foreign competition, and can at best only hope to have a share of that which was once all our own.

METEOROLOGICAL INVESTIGATION.

SCIENCE has been defined to be knowledge reduced to a system; and, if it be so, meteorology is surely not yet a science, for it is under little or no system. It is essentially based upon observation, but its observers have no settled or satisfactory system to proceed upon Different nations adopt different scales of measurement to their instruments, barometers, thermometers, rain gauges, and anemometers, while there is too often much discrepancy between the indications of the same kind of instruments. Even the modes of estimating the wind's direction and force, amount and character of clouds, and of specifying ordinary conditions of weather, are various and perplexing. The hours of observations are equally discordant. As to the records of observations, philosophers confess themselves puzzled what to do with them. The Astronomer Royal, in this year's Report to the Board of Visitors of the Greenwich Observatory, says that he is oppressed with the difficulty of making meteorological observations practically available, and adds that, "with a store of records, extensive, accurate, and rich beyond any other which exists, I yet do not see a probability of physical connections or physical laws sufficiently strong to induce me to enter confidently on an extensive comparison. The want of meteorology, at the present time, is principally in suggestive theory."

Thus the large sums spent on meteorological observations are unattended by any really scientific advance towards a knowledge of cosmical laws, although the end and aim of meteorology, if it is to maintain its claim to a science at all, must be the attainment of such knowledge. This seems to be in some measure attributable to want of concentration and unity of purpose. In this country meteorology is specially provided for by an annual Parliamentary grant of £10,000, and, moreover, is actively pursued, by way of observation, by several Government departments, at additional public expense, as the national observatories, the Army Medical Department, the India Department, the Royal Engineers, and the Royal Navy. Then every merchant ship, of necessity, is a good or bad meteorological observatory, and there are a large number of accurate private observers at home whose labours ought to be brought to a focus, and rendered available when wanted by the meteorological societies, but somehow or other this is not done. The amount thus publicly and privately disbursed annually in the service of meteorology is probably greater than that spent in the prosecution of any other science, while it is certain that no other science is so barren of practical results.

So far as we know, there is no common method, no cohesion of effort, no unity of purpose, between the different branches of the Government, not to say between them and private observers and foreign countries in matters meteorological. Each seems to act according to its own direction and peculiar bias, setting order, nature's first law, at defiance. It all seems to end in mere schedules of figures, of good, bad, and indifferent value, as exponents of climatic variations mainly, which, as they accumulate year by year, become of less and less value even for this small service to physical geography. It would be a Herculean task even to decide how much of existing records ought to be committed to the flames as inaccurate, misleading, and worse than useless, while the task of co-ordinating even on a limited scale is rendered impossible by the material being so scattered.

Since Admiral Fitzroy's method of forecasting weather was suppressed, all hope of obtaining any considerable practical advantages from current observations seems to have fled, and despair has settled in some minds as to the possibility of there being any physical connection between the phenomena observed. That there is a scientific basis for the Fitzroy forecasts has been sufficiently proved by Dr. Ballot, of Utrecht, and clearly explained in a little work, entitled "Principles of Weather Forecasts," which we reviewed in our number for January 17 last. Though a complete theory of weather changes is not yet to be hoped for, the principles established ought to be made to yield their utmost practical utility. They are steps towards it, and bring the proximate impediment clearly to light. Certain it is that if we could predict the ebb and flow of the air, as we can the rise and fall of the sea, our ability to make very valuable forecasts would be great. Here, then, is a subject to be investigated, either proceeding upon "suggestive theory" if you please, or, as we imagine, more hopefully, by careful induction. To work at such a subject with observations made at an isolated observatory, a single point in space, must be utterly hopeless; to group observations made simultaneously over a large country will not be sufficient; nothing short of the entire temperate zone must probably be embraced in such a survey. Observations made by separate offices, societies, and individuals, must be brought together and harmonized for such a purpose, including also those obtainable from all the foreign states comprised. The immense labour of reduction and conversion to the same standard of measurement must, of course, be performed before they are available for marshalling to instants of time. In such investigations the records of self-registering instruments are certainly of the greatest value, since they yield data for any assumed hour of the day, and it would be absolutely necessary to select data for each place of observation synchronous with given instants of Greenwich time, to which time all astronomical phenomena are usually referred.

If for the temperate zone the pressure of the atmosphere and the surface winds could be graphically depicted at instants separated by constant intervals, we should be able to detect the formation, transference, and obliteration of atmospheric troughs and crests; their connection with other physical phenomena could readily be traced; and, finally, the influence of sun, moon, and planets on the atmosphere could be detected by this method, if by any. Hence it seems that something more is needed besides suggestive theory. There is needed unity of design in modes, measures, and purposes—co-operation between individuals, authorities, and nations—in the laborious and intricate pursuits of meteorology.

ARTIFICIAL LIGHT IN PHOTOGRAPHY.—No. I.

THE student upon first beginning the study of photography soon finds that he must get rid of two popular errors, namely, that any bright light will do for photography, and that photographic impressions cannot be taken in perfect darkness. He soon discovers that pure yellow, red, and orange rays of light, however bright they may be, have no effect upon sensitive photographic plates. Also, if he be under the care of a good teacher, the fact will be explained to him that some of the extra-violet rays of the spectrum, quite dark and invisible to the eye, will impress a photographic image, so that it is easy enough, by way of experiment, to print a picture upon a sensitive collodion film without the presence of light. Now, as artificial lights vary very much in the rays they emanate, they vary also in photographic power, it being evident that a very bright light, rich only in yellow rays, and poor in the others, is calculated to deceive the eye as to its practical photographic value. Hence our present summary of the value and method of producing different kinds of artificial light for photography may prove useful. Artificial light is not much used in portraiture, except by way of experiment for purposes of amusement and instruction, but in enlarging processes and in printing of transparencies it is largely used in commerce.

The richest artificial source of photographic rays is the electric light, which contains waves even more refrangible than those in the light of the sun. Glass is opaque to most of these very refrangible rays, cutting them off as effectually as a lump of coal; hence, when it is desired to utilize them photographically, either rock-crystal, or no media at all, must be interposed between the light and the sensitive film. In practice, it is not an economical plan to attempt to utilize these rays, as, in aggregate actinic power, they are infinitely lower than the rays transmitted by all good thin colourless glass. For experimental purposes, however, they may be utilized by interposing only plates, prisms or lenses of colourless rock-crystal, not glass The electric light being so expensive and troublesome to work, and requiring a large preliminary outlay of capital, is not used in photography by amateurs, though public companies, and men in a very large way of business, find its employment to be, photographically, advantageous. The very few who use it discard the Grove's battery as the source of power, and substitute one of the new induction machines driven by a small gas or steam engine. In the Woodbury process, the induction machine turned out by the Alliance Company, of Paris, was, after trial, preferred to all others, and the lamp preferred was one invented by a workman in Mr. Woodbury's employ. Grove's batteries are not only troublesome and costly things to keep in order for the daily production of the electric light, but when they are properly managed, as at the Royal Institution, it is found to be two hours' work to charge and prepare for use a battery of forty or fifty cells. As few of our readers are likely to want to use the electric light in photography, the foregoing information will doubtless be sufficient on this head.

The magnesium light is very rich in actinic rays, and is of great value in photography. When magnesium ribbon was first made, it was burnt by holding a piece of it in the fingers. Next, it was pushed slowly through a piece of tube and permitted to burn as it came out, and then clockwork apparatus was designed to deliver the ribbon with regularity through the tube. A reflector was placed behind the light, and a pan was placed beneath, to catch the ash falling from the flame. This was the earliest magnesium lamp, but it is objectionable for several reasons. First, it is the most costly method of burning magnesium; secondly, the falling ash sometimes breaks off in a lump, close to the metal, and this puts out the light; thirdly, the smoke to a small extent sometimes comes in front of the flame, and diminishes the light.

The lamp invented by Mr. Henry Larkins is a clever little piece of work, and gives a greater amount of light, with the least

Digitized by Google

expenditure of magnesium, than any of its competitors. But in photography it has also disadvantages of its own. In this lamp the magnesium, in fine powder, is mixed with fine dry sand. The mixture, placed in a reservoir, in the upper part of the lamp, falls through fine metallic sieves into a descending tube. The lower orifice of this tube is kept in the small flame of a gas jet, or spirit lamp with horizontal neck. A little handle enables the operator to open or plug the tube, so that he can let the powder fall, or stop it at will. When the powder falls through the flame, of course it is ignited, and every atom of magnesium falling is entirely consumed. The brightness of the light depends upon the quantity of magnesium in the powder, the larger the proportion of metal, the longer being the pendant flame. When the proportion of metal is very small, the light resembles a bright flickering star, but as the proportion increases, the flame lengthens downwards, till it may be made to assume the shape of a tongue four, five, or more inches in length. The flickering character of the light, when the flame is small, is one objection to the lamp. Another is, that in photographic enlarging it is necessary that the light should emanate as much as possible from a point, and that the front of the flame should be free from smoke. These requisites may perhaps be obtained in the Larkins' lamp, by using a small flame behind and close to a circular orifice as big as a sixpence, or shilling, supplying the flame with air through that orifice only, so that all smoke formed in front of the flame shall be at once carried away. We are not aware that such a lamp for enlarging has yet been constructed. The ordinary Larkins' lamp is of handsome external appearance and made of copper, tinned and polished inside. Some few lamps have been made by the inventor for public illuminations, and two of these large ones were once exhibited outside the Guildhall, on a festive evening, with such effect that expensive gas devices in the neighbourhood were utterly spoiled and extinguished by the glare from the two lamps made by Mr. Larkins.

The principle of supplying air to the front of the flame only was first adopted in America, and is good in all magnesium lamps where intense light is desired in one direction only. Lamps on this principle were at first furnished with a funnel-shaped opening in front, but then it was impossible to close the larger mouth of the funnel with a lens or sheet of glass, because these solid media would stop the supply of air. This difficulty was overcome by Mr. W. H. Harrison, who substituted a double funnel, the outer larger than the inner, and projecting further from the main body of the lamp. This outer funnel was closed at its larger orifice with a sheet of glass, and a wide tin tube in the side of the outer funnel admitted air, which passed on to the front of the inner funnel, and then rushed through it to the flame. By means of a piece of india-rubber tubing slipped over the outer orifice, other gases than air might be supplied to the flame at the will of the operator, thus making the lamp useful for experimental purposes. This modification is suitable either for powder or ribbon flames.

The best lamp for burning magnesium ribbon was invented in America, and is now obtainable in England, we believe, of the Magnesium Metal Company, at Manchester. In this lamp the ribbon, driven by clockwork, passes vertically down the chimney of the lamp, and is burnt between two pairs of metallic rollers. The upper pair of rollers gently pinch the ribbon and draw it downwards. The lower pair carry a knife edge at one part of the circumference of each, so that every time the two knife edges meet, which is once every revolution, they nip off the heavy ash hanging from the flame. This lamp, which is supplied with air from the front only, is very efficient in action, and the flame is not so liable to go out as in the old form of ribbon lamp.

A very great objection to magnesium is the large quantity of white smoke, or magnesia, which it gives off, necessitating the use of chimneys communicating with the outer air, otherwise the room is soon full of smoke. Another objection is its very high price, which, for many purposes, does not permit it to compete with the lime light.

We note the remarks of our contemporaries about English and French lenses, and shall have more information to give on the subject shortly.

TECHNICAL EDUCATION AT THE POLYTECHNIC INSTITUTION.

THE question of technical education has been now fairly brought under the consideration of the Legislature. And we find that in this, as in other good causes, there have been silent workers whose sole reward is the satisfaction of doing their duty. These have done, and still are doing, much that is praiseworthy on behalf of those who are desirous of helping themselves. We are led to these observations from having before us the last number of the "Society of Arts' Journal," in which there are twenty pages of closely printed matter containing particulars of the prizes and certificates awarded to successful candidates in their recent examinations on science subjects. Amongst them there appear as their instructors, and to the efficacy of whose teaching these students bear silent witness, such names as the "Mechanics' Institute," "Young Men's Christian Association," "Working Men's College," "Workmen's Club," and a score of other such terms that testify in unmistakable language that "Technical Education" is a practicable reality. But there is one institution—the first, in fact, that meets our observation on examining the list referred to in connection with the highest prize—more popular, we may venture to say without offence, than any other we have named, and which, like them, is always ready to furnish instruction to all. But, not content with educating a circle of students, it proceeds beyond—to those who seek amusement. If, by proffering such it imparts one iota of information, it is gratified, but is only satisfied when ultimately that information creates a desire for deeper and more solid instruction. How many students have been enlisted through the medium of this institution into the army of intelligence, let the journal now before us say. There we find that the recipient of the Prince Consort's prize is a student of the Royal Polytechnic Institution. There, too, we find that the Royal Geographical Society's prize has been awarded to another student of the Polytechnic. The "Gardeners' Chronicle" prize has been awarded to a third student of the same institution. In like manner, we find on looking through the list that no less than seven other prizes and forty-five certificates have been awarded in the recent examination to Polytechnic students. Now, this must be truly gratifying to all who have the interests of technical education at heart; and, too, it must be a source of peculiar satisfaction to those who conduct the affairs of the Polytechnic Institution, whilst the general public must acknowledge the benefits it is silently conferring upon mankind. It has been said that there is no royal road to learning; true, but there is a Royal Polytechnic road, and those who travel thereby may hope to realize royal results—as we have just shown has, in one instance, been done. When any of our readers next pay a visit to that cradle of the arts and sciences in Regent-street, and whilst absorbed in the lectures, or smiling at the more mirthful phases of practical science, let them remember that there is a well of truth to be explored within the very same walls. We would have them know, too, that while they are being entertained by Professor Pepper there is yet another friend with whom many have not yet made acquaintance—the Rev. Charles Mackenzie. This gentleman is the founder of the Polytechnic Science Classes, and is always ready to welcome and encourage them in the arduous, yet peaceful, paths of knowledge.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

CARRE'S PNEUMATIC ICEMAKING MACHINE—PROTECTION FOR THE EYES OF METAL WORKERS—MODE OF OBVIATING DEVIATION OF THE COMPASS IN IRON SHIPS—THE MANUFACTURE OF DIAMONDS.

LAST summer we described a pneumatic ice-making machine, the invention of M. E. Carré, of Moislaus. Our account attracted a good deal of attention, and brought numerous inquiries; and we recur to the subject now, as the machine was exhibited, for the first time in England, by Dr. Roscoe, at the conversazione at the College of Physicians last week, and was found to fulfil all the invention promised. It is, as we explained, a simple air pump, under the receiver of which the carafe, decanter, or vessel of water to be frozen is placed. The action of the pump necessarily causes the rapid evaporation of the water, and consequent reduction of temperature. So far all is very simple; but now comes the most ingenious part of M. Carré's invention. To remove the atmosphere of aqueous vapour resulting from the exhaustion of the air, it is made to pass over the surface of some strong sulphuric acid, kept in agitation by a peculiar contrivance, so that a large surface is presented to the vapour. By this means rapid absorption of the vapour takes place, and, consequently, rapid evaporation and reduction of temperature; so that, in about three minutes, a decanter of water is reduced to the freezing point. An apparatus for congealing one decanter at a time costs only four pounds. There is but one drawback to the very extensive use of this ingenious apparatus, and that a little instruction would quickly remove. The sulphuric acid soon becomes too dilute to absorb the vapour of water. A chemist knows how to deal with this dilute acid, which only requires to be evaporated to be ready for use again. But with ordinary people it will always be a difficulty and a loss.

Another very useful invention to which we drew attention in our number for March 20 last, was Cohn's mica spectacles for the protection of the eyes of metal workers, masons, and stonebreakers. We have recently had an opportunity of trying these instruments. They are extremely light and agreeable to wear, and must afford the most complete protection to the eyes from splinters and scales, while the peculiar non-conducting power of mica for heat makes them especially useful to furnace workers, who are apt to suffer from inflammation of the eyes. To the information we have given before we can only add a statement showing the economy of their use. In one establishment reported on by Dr. Cohn, injuries to the eyes cost the sick fund 1,575 thalers in one year. If the spectacles had been in use and the injuries prevented, a saving of 1,318 thalers would have been made, the difference, 157 thalers, being the cost of supplying all the workmen in the shops with the instruments. Our workmen are, in general, for reasons we need not stop to inquire into, slow to adopt protective measures; still, we hope to see mica spectacles extensively adopted in our workshops.

All difficulties about the deviation of the compass in iron ships have been overcome, according to his own account, by M. Arson, who divides the ship longitudinally into two halves, and interposes throughout the whole length a plate of non-magnetic metal—copper, for example. Thus the ship has four magnetic poles, and by the equal counteracting influences of these, the indications of the needle are made correct. There is an appearance of probability in this idea, but great practical difficulties would be found in the way of completely insulating the two halves of the ship.

Another suggestion for the manufacture of diamonds, about which men will, no doubt occupy themselves until the now prized jewels

Digitized by Google

are as common as flint pebbles. The present inventor directs a stream of chlorine gas upon cast iron kept in a state of fusion. The iron is sublimed in the form of perchloride, and the carbon is left behind, but not, we expect, in the shape of a diamond. Carbon is present in cast iron in the graphitoidal form, and all our experimenter could get for his trouble would, we think, be a little blacklead.

PARLIAMENTARY NOTES.

THE House of Commons had a busy time of it on Monday evening, no less than a quarter of a hundred questions having been under discussion, some at considerable length. Of these, of course only a few possess an interest to our readers beyond their political bearing. Scientific instruction abroad has been reported upon by our legations, and we have as yet no published information upon this important point. Mr. Samuelson therefore asked the Vice-President of the Committee of Council on Education what was the cause of the continued delay in the production of this information. Lord R. Montagu said the delay had arisen solely from the immense mass of matter. The translator was proceeding as quickly as possible, and the copy was being forwarded in batches to the Foreign Office, where the reports were addressed. Lord Stanley promised to enquire whether there was any delay at the Foreign Office; he believed a great part of the papers were already in print.

With reference to the case of the "Tornado," Lord Stanley was asked by Mr. Smollett if any authoritative decision had been given by the Spanish tribunals, whether the claims of the crew for compensation for harsh and unjustifiable treatment were still under consideration; and if he was prepared to lay upon the table of the House any further correspondence in the matter of the seizure of the ship and the prolonged detention of the crew of that vessel. His lordship, in reply, said—I regret to say that no authoritative decision has yet been come to on the subject. I have more than once made representations to the Spanish Government, but the answer has always been the same—that the Government could not interfere with the ordinary courts of law. With regard to compensation, that will depend on the amount adjudged to the vessels when the decision shall be given. A few weeks ago I laid upon the table such papers as I had, and since that time nothing of importance has been received.

In the course of the evening, Mr. Goldsmid asked the Secretary to the Treasury whether, in consequence of the opening of the Fell Railway over Mont Cenis, Her Majesty's Government intended to adopt the Brindisi route for the Indian mails; and whether they had made any application to the French Government to put an end to the twelve hours' detention in Paris of letters posted for Italy by the evening mails.

Mr. Sclater-Booth thought it was premature at present to form an opinion as to the necessity of immediately changing the route for the Indian mails. The subject was fully considered by a select committee which sat in 1866, and, anticipating the opening of the Fell Railway, a very elaborate report was presented to the Post-Office by Captain Tyler. On the settlement of the contract with the Peninsular and Oriental Steam Company last November, it was stipulated that the Brindisi route should be adopted in preference to Marseilles if circumstances rendered the change expedient. With regard to the latter part of the hon. member's question, he was informed that although the detention operated inconveniently for letters from London, this was not the case with respect to provincial letters, and that the present arrangement was most convenient for the French service and for all parties interested.

Delay in another matter—that of the Electric Telegraphs return, ordered by the House on April 21 last—was complained of by Mr. Ayrton, who asked the Vice-President of the Board of Trade when the return would be presented; and what was the cause of the delay in preparing it and the annual returns relating to railway companies.

The railway companies themselves appear to be the impediments, as, from Mr. Cave's reply, it appears to be impossible to say when the return relating to electric telegraphs would be presented. Notwithstanding a second circular, the required information has not been received from the London and North-Western, London and South-Western, Midland, Manchester, Sheffield, and Lincolnshire, Great Northern, Great Western, Caledonian, and other railway companies. It is evident that without particulars from these large railway companies the return will be so incomplete as to be entirely useless. A similar answer was given to the second part of Mr. Ayrton's question, Mr. Cave observing that the delay in presenting the compiled annual returns of the railway department was due to the failure of the companies to send in the particulars earlier. These particulars were compiled daily as they arrived at the Board of Trade; so that as soon as the last details were received the compiled return was ready for presentation, allowing a few days for computing the totals. It was generally also in type at the same time ready for printing. Last year the railway companies required no less than five reminders before the whole of the returns were made.

FLOATING WATER-WHEELS FOR SIAM.

THE practice of utilizing the power of the tides and currents of rivers for the working of machinery is of ancient date, and is, in some parts, largely adopted in the present day, as, for instance, on the Danube, where a vast quantity of corn is annually ground by tide power. The principle has just been applied, on a small scale, to pumping purposes for the King of Siam, by Messrs. Owens and Co., the hydraulic engineers, of Whitefriars, who have completed the first of a series of floating water-wheels for supplying water to the King's Palace, at Bangkok. This river water-wheel, which we recently saw at work on the Thames, is fixed on a wrought-iron punt 16ft. long, 5ft. broad, and 2ft. 6in. deep. The wheel is 5ft. diameter, with paddles 2ft. broad, and working treble 2-inch plunger pumps of 9in. stroke, and fitted with india-rubber disc valves. Messrs. Owens were consulted by the King of Siam with reference to supplying the four grand palaces at Siam with water, and finding no fall of water from which to obtain motive power, adopted the present means of accomplishing their object. The velocity of the stream ranges from two and a-half to four miles an hour—about the same flow as on the Thames—and the apparatus will have to force water a considerable distance to an elevation of over 100ft., supplying from 3,000 to 5,000 gallons in the twenty-four hours. This, in the recent trials on the Thames, it proved itself quite capable of doing, working equally well on each change of the tide.

THE WHITWORTH SCHOLARSHIPS.

REPLIES have been received from the following towns and educational institutes intimating the number of exhibitions of £25 they are prepared to accept for the year 1868:—Manchester, Owens College, 8; Manchester Free Grammar School, 2; Oxford University, 3; Cambridge University, 3; London Univerity, 3; Durham University, 1; Dublin Trinity College, 1; Edinburgh University, 1; Edinburgh, Watt's Institution, 1; Glasgow University, 1; Glasgow, Andersonian University, 1; Ireland, Queen's University—Belfast, Queen's College, 1; Cork, ditto, 1; Galway, ditto, 1; London, King's College, 1; London University College, 1; Eton College, 1; Winchester School, 1; London, Charterhouse School, 1; London, Christ's Hospital, 1; London, City of London School, 1; Shrewsbury School, 1; Marlborough College, 1; Cheltenham College, 1; Clifton College, 1; Liverpool College, 1; Derby Grammar School, 1; College of Preceptors, 2; Science and Art Department, 3; Society of Arts, 3; Birmingham, 1; Bristol, 1; Swansea and Cardiff, 1; Halifax, 1; Northampton, 1; Sheffield, 1; Brighton College, 1. Only eight answers remain to be received.

TRIAL TRIP OF THE "TRAVANCORE."

THE "Travancore" is the latest addition to the Peninsular and Oriental Company's magnificent fleet of steamships, which was built and engined by Mr. John Key, of Kircaldy. On Wednesday week, this vessel made her trial trip, leaving Southampton Docks at 11·30 a.m., and proceeding direct to Stokes Bay, where one run was made on the measured mile. She then steamed round the Isle of Wight, returning into Southampton Water at six o'clock. The "Travancore" is a screw steamer of 400-horse power nominal (indicated power duing the run, 1,405); her gross tonnage being 1,899¼, and registered ditto, 1,185; length, 281ft. 6in.; breadth of beam, 35ft. 5in.; and depth of hold, 27ft. 8in. Her true mean speed when on the measured mile, with a strong southerly wind blowing, was 12·245 knots; steam, 24lb.; vacuum, 22in.; revolutions of engines, 59. She had 754 tons weight of coals, water, and stores on board, and her draught was 16ft. 6in. forward and 18ft. 2in. aft, the mean being 17ft. 4in. There was a large party of ladies and gentlemen on board. The "Travancore," which is commanded by Captain R. Methven, one of the oldest officers in the service, has, since her trial trip, left with the outward India, China, and Australian mails, and on her return from this voyage she will be despatched to the other side of the Isthmus of Suez for service on those stations. Two more large screw steamers, of 3,000 tons and 600-horse power each, are now in progress for the company, viz., the "Magdala," constructing by Messrs. W. Denny Brothers, at Dumbarton; and the "Hindostan," by Messrs. Day and Co., at Southampton. The "Magdala" is expected to be ready for sea in about six months, and the "Hindostan" in about thirteen months.

ROYAL BOTANIC SOCIETY.

THE second grand exhibition of plants and fruit for the season was held on Wednesday last in the Society's Gardens, Regent's Park, and was highly successful both as regards visitors, of whom there were between 9,000 and 10,000, and flowers and fruit, which were there in splendid variety. The pelargoniums, roses, azaleas, and orchids were very numerous and well grown and covered with perfect blooms, many of the roses being full 6in. across. There were also many fine heaths, well deserving attention, and many fine specimens of palms, for which a special prize was offered by a member of the society. There were good collections of stove and greenhouse plants, containing plants famous for their fine leaves, and very many rare plants especially to be admired for their fine flowers. Superior fuchsias, double and single, a great variety of rare and curious plants, such as the famous pitcher plant, of which there were many specimens, and for which a special prize was given; new petunias; new and fine gloxinias, Japanese lilies, new ferns, dwarf myrtles; new and fine varieties of scarlet and variegated pelargoniums, and an interesting collection of economic plants, for which a special prize was given. The collection of orchids was very good. A noticeable feature was a bed of "economical plants," comprising tea, coffee, pepper, india-rubber, arrow-root, nux vomica, rice, sugar cane, and other plants of medicinal or general employment.

BOILING DOWN.

A VISIT to the boiling-down establishment at Colbinabbin station, says the "Melbourne Argus," is not without interest. When the sheep have been killed, skinned, and cleaned, and the vat emptied and made ready, a number of hands are employed in chopping them into three or four pieces, and then throwing them into it. The vat is 11ft. high, and tapers from the top to the bottom. The tapering does away with the necessity of employing any person to pack the sheep in the vat, as the pressure above always keeps the carcasses close together; and, as they fall to the bottom when steam is applied, room is left for the fat to swim on the top. Steam is conveyed from an engine of 40-horse power, which is in connection with the patent wool-scouring machine in the adjoining shed. The vat holds 300 wethers or 400 ewes, and 1,000 of those are stewed (for really that is the most expressive term to apply to theprocess) in forty-eight hours. When the fat has been all extracted, it is allowed to flow out of the taps, so placed in the side of the vat as to allow nothing but fat to flow into large 500-gallon coolers. The gravy runs from a tap in the bottom of the vat into a reservoir prepared for it, and is afterwards given as food to pigs, who luxuriate on what would be a great blessing for the poor in some of the large and populous cities in the old country. All the bones and shreds of meat are drawn out and carted away to the same herd of unclean animals. Such is the power of the steam employed that the bones are made so soft as to break in pieces in the hand, the marrow being completely melted out of them. A number of coopers are employed making casks, which are afterwards filled from the coolers, and then headed up and sent to the train for conveyance to Melbourne.

THE Bristol and Exeter Railway Company are about to build a cattle market at Bridgewater, in Somersetshire.

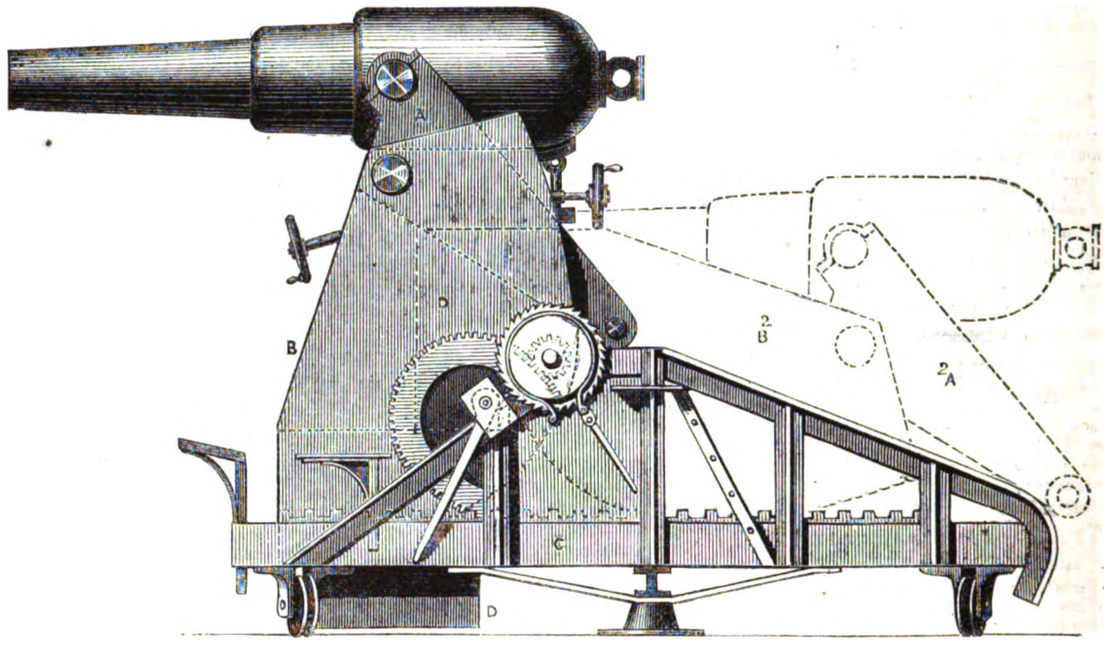
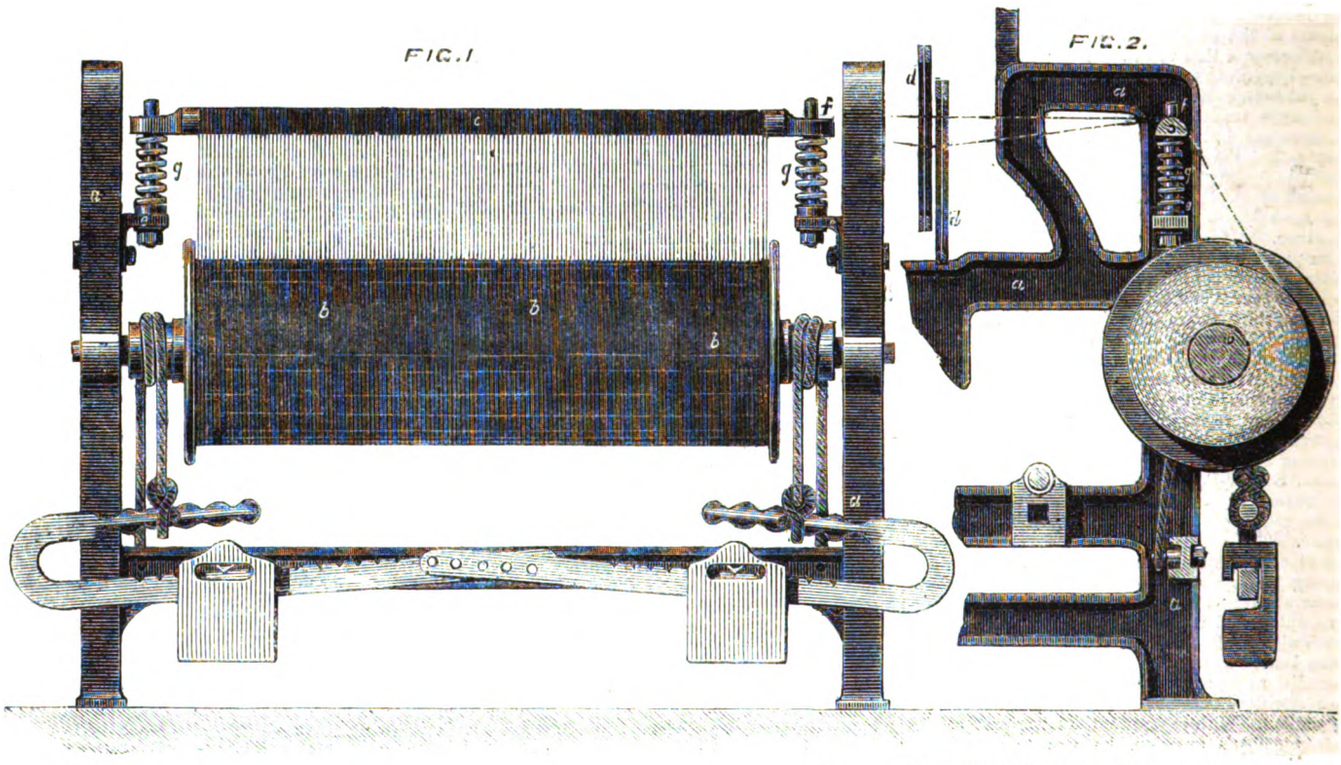
SYSTEM OF WORKING HEAVY GUNS.

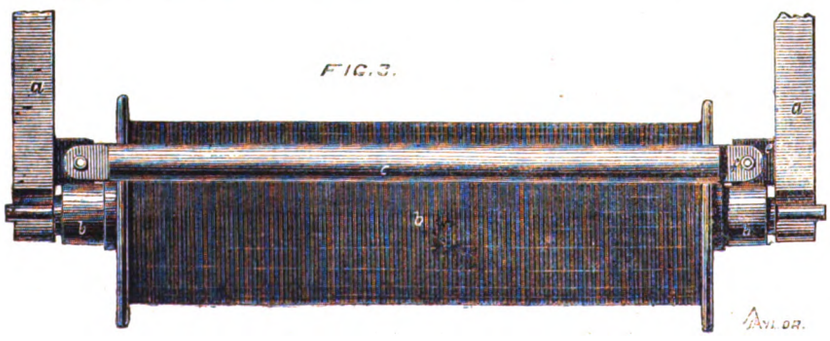
BY CAPTAIN A. MONCRIEFF.



IMPROVED LOOM.

BY MR. R. CARTER.





IMPROVEMENTS IN LOOMS FOR WEAVING

MR. ROBERT CARTER, of Leyland, near Preston, has recently patented some improvements in looms for weaving, the objects of which are to cause the yarn to weave easier by reducing the friction on the healds and reed, and also the friction on the yarn itself, and at the same time to effect a saving in the power necessary for driving. The invention consists in placing the back carrier or rest on spiral springs supported by studs or pins and brackets fixed to the side frames of the loom, so that the springs and carrier or rest will yield to the pressure of the yarn and thus reduce the friction upon the healds and reed as well as upon the yarn itself, and thus cause the yarn to weave easier as well as economize the power required.

Fig. 1 on the annexed engraving is a back view of

Digitized by Google

so much of a power loom as is necessary for the illustration of this invention, which is shown as applied thereto; fig. 2 is a cross section, and fig. 3 a ground plan of the same. *a a* are the side frames of the loom; *b b* the yarn beam; and *c c* the back carrier over which the yarn passes from the yarn beam to the healds *d d*. Bolted firmly to the two side frames are two brackets *e e*, in which are fixed vertical studs or pins *f f*; resting on these brackets, and coiled round the studs, are placed helical or spiral springs *g g*, and upon the upper ends of these springs rest loosely the ends of the back carrier *c c*, the ends of the carrier being pierced with holes fitting loosely over the studs or pins for that purpose. By this arrangement and construction of the parts the springs and carrier will yield to any undue pressure on the yarn and thus prevent any breakage, and by reducing the friction cause the yarn to weave easier, as well as economize the power required to drive the loom. The springs also can easily be replaced or renewed when required, and springs of different strengths may be adapted for different kinds of work by merely lifting the back carrier off the studs.

THE MONCRIEFF SYSTEM OF WORKING HEAVY GUNS.

IN our notice of the second soirée of the Royal Society we briefly referred to Captain Moncrieff's system of working guns, promising further particulars and drawings in due course. We now place these before our readers, premising that this protected barbette system promises not only to be one of the greatest improvements ever introduced by a single individual in the art of working heavy ordnance, but to completely revolutionize the construction of fortifications. The records of war prove that there is no defence against shot and shell equal to a simple bank of earth or sand; but heavy guns cannot be well worked behind sand banks in the ordinary way, and, therefore, it is that we have shields of iron and walls of masonry. It is excessively difficult to use sand banks unless the guns are virtually mounted *en barbette*, that is to say, pointing over the parapet instead of through it. Guns so mounted are greatly exposed, and their detachments are, while loading, at least, quite, or nearly quite, unprotected. Captain Moncrieff long since conceived the idea of obtaining a system of firing over a solid parapet, preserving free lateral range—which cannot be done while embrasures are retained—and neither exposing the gun and detachment nor involving the labour of raising and lowering the piece—in a word, of gaining all the advantages without introducing any of the defects of the barbette system. After many experiments, he has produced a gun carriage which has already been tested with great success.

The principles involved are that the gun should be lowered down behind the parapet to be loaded in safety, to be raised above the parapet for a moment only and fired, and then suffered to sink once more to its *cache*. In addition, it was necessary that all this should be done without complex machinery or requiring the expenditure of great power. As regards the last point, Captain Moncrieff was not slow to perceive that much energy is wasted by the recoil of a gun in overcoming the friction of compressors, and this energy he proposed to store up in a heavy weight to be raised by the recoil of the gun down a slope, and by its subsequent fall to elevate the gun once more over the parapet. The details of the invention by which these principles are applied in practice are, as will be seen, extremely ingenious. In the Moncrieff carriage the recoil is stopped without injurious strain by an arrangement of forces analogous to those which stop the rolling of a ship, where the gradual rising of the centre of gravity of the whole structure puts a limit to the movement in one direction. The curve of the elevators can be made to control the metacentre, and express the same movement with nearly the same results.

Captain Moncrieff first submitted his invention to the Government in 1858—ten years since—and he has partly worked out its application to three different classes of artillery, namely, siege artillery, the heaviest class of garrison artillery, and ships' guns and floating batteries. One form of the second application is the one illustrated in our engraving. For this class of guns Captain Moncrieff confines himself to the force of gravity for absorbing recoil. In the other two cases the Captain likewise uses gravity wherever it can conveniently be applied, although he has also matured plans for absorbing and utilizing recoil by means of other forces. Our engraving shows the general arrangement of a Moncrieff carriage for a 7-ton gun. It consists of three principal parts, viz., the carriage proper, A; the elevators, B; and the platform, C. The dotted lines A^2, B^2, show the carriage and elevators near the loading position. It traverses on a central pivot and a single circular racer 14ft. in diameter, and the platform is about 16ft. 6in. in length. A counterweight D, sufficient to balance the gravity of the gun, is placed between the two elevators. In the firing position the centre of gravity of counterweight and the fulcrum on which the elevators rest are nearly coincident, and are both in nearly the same vertical plane as the trunnions of the gun. On the discharge of the piece the elevators roll backwards on the platform, causing the gun to descend in a cycloidal curve, while at the same time the counterweight rises, at first with an increasing velocity. The centre of gravity of both the gun and the counterweight together is also the centre of the circular part of the periphery of the elevators; this being the portion on which the elevators first roll, after firing, it follows that the common centre of gravity of the gun and counterweight travels backwards in a horizontal plane. And as this circular part is about a quadrant the detachment is enabled to work the gun for drill purposes or to place it under cover from the firing position with ease, the whole structure being in a state approaching to stable equilibrium. As soon, however, as the elevators pass off the circular arc on to the greater curve, the leverage in favour of the counterweight goes on in an increasing progression until it becomes sufficient to meet the utmost force of the recoil; thus the recoil is absorbed without necessarily using friction, and it will be observed how this arrangement takes off that shock and vibration which proves so destructive to pivots and masonry in the ordinary carriage, and which has led to so much expense lately in making foundations strong enough for the platforms of heavy guns. When the gun has recoiled as far as it will go it is held in that position by a self-acting pawl, and then loaded under cover. The elevation can also be given to it in this position if desired, as there is a trunnion pointer with segmental scale on the cheek of the carriage. If the pawl is lifted the energy of the recoil stored in the counterweight raises the gun into the firing position, its movement upwards being regulated by one gunner holding the handle of the friction band.

A careful examination of Captain Moncrieff's system discloses many and important advantages. Its adoption will probably enable us to dispense with our present costly and inefficient system of coast defences. The fact, however, cannot be disguised that Captain Moncrieff has not yet quite perfected his system, but he has in view several modifications and improvements. Besides, practical trials must be made in order to ascertain defects with a view to their remedy. But even taken as it stands the system undoubtedly possesses great merits and is a valuable improvement upon all previous methods of working heavy guns. Not the least important part of the system is the arrangement advocated by Captain Moncrieff of arming positions by means of small detached works in which guns mounted in Moncrieff gun pits or batteries support each other by their fire. The lateral range of the guns instead of being limited, as at present, to a maximum angle of 70deg., extends through the whole circle if required. Hence, in detached works, the value of each gun is increased by the increased lateral range it controls. In conclusion, we may observe that Captain Moncrieff has introduced a very ingenious reflecting sight, by the aid of which aim can be taken without exposing a man.

ELASTICITY IN RAILWAY STOCK AND THE TRACK.

NO one familiar with railway operations will deny the importance of applying some degree of elasticity to the track, and so applying it that the effects can be secured in the depth of winter as well as when the frost is absent. A well ballasted road bed with properly adjusted superstructure, will in the milder season of the year give what is popularly supposed to be about the requisite degree of elasticity, but how far this popular supposition is correct, the rapid depreciation of even the best specimens of this track will show, even in the most favourable weather, where the traffic on the road is heavy. All experience shows that the character or the amount of elasticity obtained by ballast and wooden crossties does not fulfil the requisition, as the large amounts annually expended for track repairs, and repairs of rolling stock, sufficiently show. What is really required is something more permanent, and a material not so subject to climatic influences. A rain storm will so saturate even the best ballasted road that the blows of the driving wheel at the rail-joints will rapidly cause depression and displacement of the ballast, and this displacement once commenced, becomes a source of expense and destruction in the rail, road bed, and every part and portion of the rolling stock. It has been demonstrated that the driving wheel of a locomotive passing a depressed rail-joint, say at a speed of twenty-five or thirty miles to the hour, will jump some fifteen or more inches over the depression, and strike with crushing weight upon the opposite side. How much of a disturbing and destructive force this jumping process is, any one will easily comprehend who has ridden on the footboard of an engine running over a rough road, and they will comprehend likewise how little gravel ballast iron rails or wooden cross-ties can resist the force of many of these blows. The common "permanent" way is the most unpermanent thing on earth; it is never in plane, and often out of line, enough to cause a useless expenditure of power. If broken stone is substituted for gravel for ballast an advantage is gained, but not enough to pay for the extra expense, unless the facilities for supplying and applying it are extremely favourable. What is needed is some material that is in a measure independent of climatic influences. If blocks of stone were sunk in the road-bed deep enough to resist the action of the frost, and the rails laid in chairs upon an elastic cushion of rubber, then the problem is solved, so far as permanence of material and independence of climatic effects. Then comes the mechanical problem of securely fastening the chairs to the stone blocks; that mastered, it would seem that a really "permanent way" is secured, and a firm, even and elastic track secured. The interposition of an elastic bearing for rails, and a solid immovable foundation, would be a vast advance upon present practice; it would double the life of rails and exercise a corresponding beneficial effect upon the rolling stock.

We hear a great deal of broken tyres, axles and other parts of the locomotive and the car, a vast majority of which we have not the least doubt could be prevented by a really elastic truck. Once secure this permanence of foundation and elasticity of superstructure, corresponding improvements would be made in the rolling stock, although in the latter a great comparative advance has been made. The whole tribe of rigid long wheel base engines should be given up, and flexible devices, such as Bissel's pony truck and Hudson's equalizer, substituted for the present stiff and unyielding running gear. The same reform should be made in tenders, and the trucks so arranged that the wheels can pass through curves without that hard abrasion and strain between the rail and wheel which is so destructive to both.

The modern tender, with its innumerable wheels, castings, springs, and other accompaniments, is a prolific cause of trouble and expense. It needs to be simplified instead of complicated. Bissel's tender truck is an improvement in the right direction. It does away with one set of wheels on the forward truck and has a single centre bearing spring immediately over the axle, which is a decided improvement over side springs, which on an uneven load throws the whole load first upon one side and then rebounds upon the other. The forward axle is connected with the back truck by a lever which swivels in the centre between the bearings, and thus enables the tender to pass curves of short radius with the greatest ease. The centre bearing and nearly straight spring likewise equalizes the weight upon the forward wheels, and gives a very easy movement to the tender, entirely different from the short thumping up-and-down motion so observable in most tenders. This improvement, and those alluded to in the engine, give an amount of flexibility to the whole machine favourable to the track. A common mistake is using springs with too sharp a curve; the nearer they approach the form of an arch, the stiffer and harder they are in their action. When they are nearly straight under the full load they give an easy vibratory movement entirely different from the hard jerky motion so noticeable in some engines and tenders. It is a mistake to suppose that merely putting more springs upon a machine will give it the requisite elasticity: we rather want better and more philosophical application of them. Springs should be so applied that they will take up the shock of opposing forces controlling them to a given end. It is possible to have too much as too little elasticity both in the running gear and in the truck. A fine adaptation of electricity, so as to produce the best effects at the least expense, is a triumph for the mechanical engineer, and we know no place where this study can be pursued with such good effects and where the field of enquiry is so broad as in railway machinery. The really practical engineer, who, in addition to his daily experience, is willing to take the experience of others and compare results with the truly catholic desire of arriving at the truth, will hardly fail of finding that great improvements are possible in the construction of the track as well as the rolling stock. —American "Railway Times."

THE SCIENTIFIC WONDER.—Have you seen it? It magnifies 32,000 times. Price thirty-two stamps (post free), with book of full instructions. To be had only from A. McCulloch, Philosophical Instrument Maker, 18, Blucher-street, Birmingham.

N.B.—For further particulars, see Advertisement in this paper, page 1, column 2, headed "Scientific Wonder."—[ADVT.]

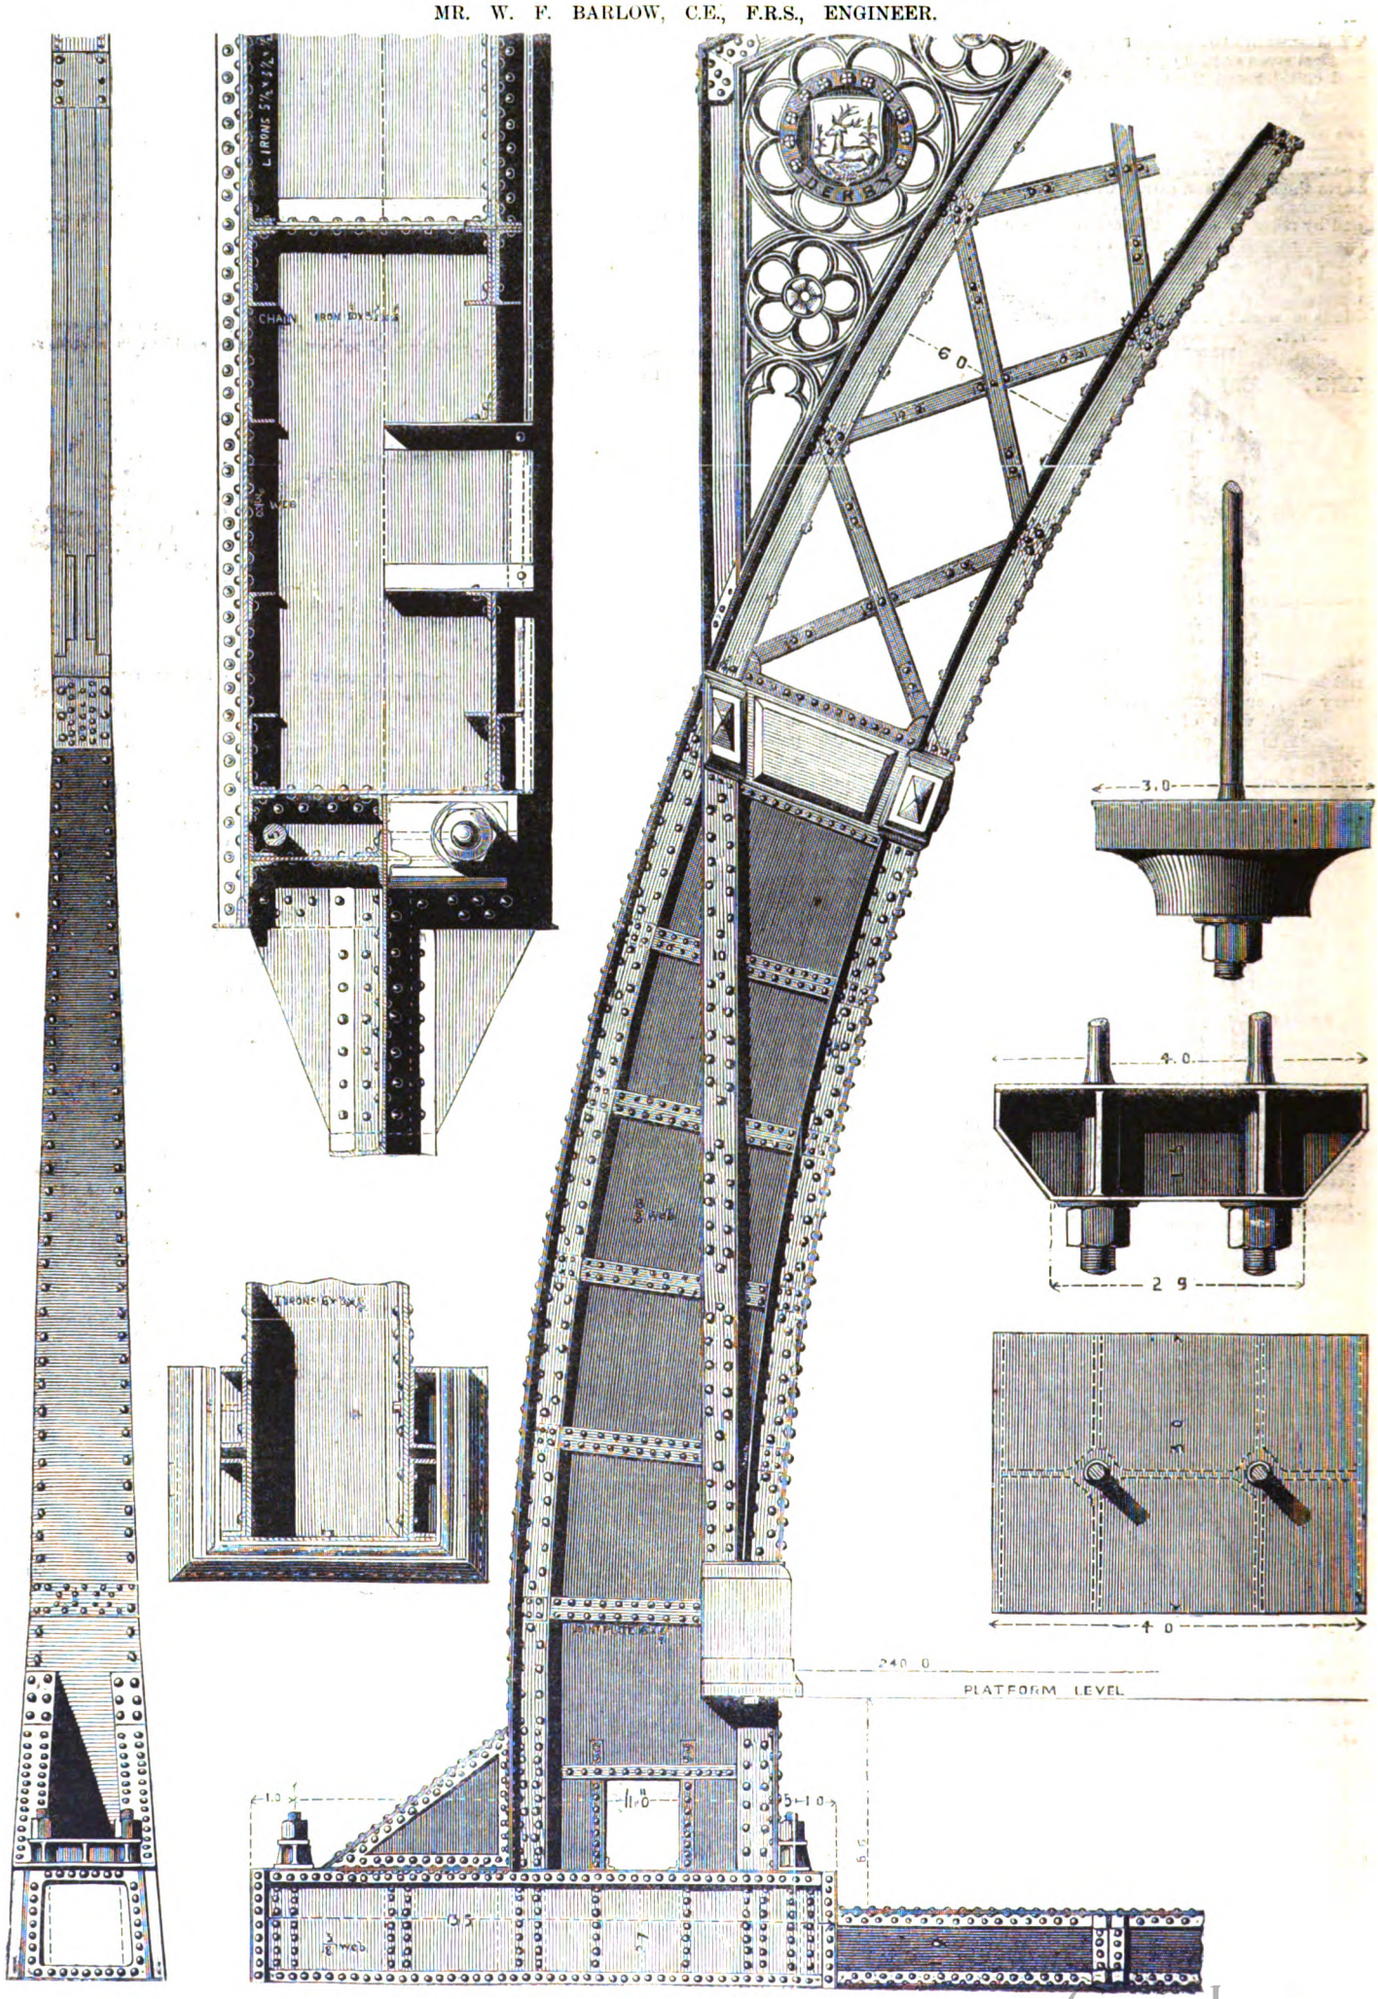
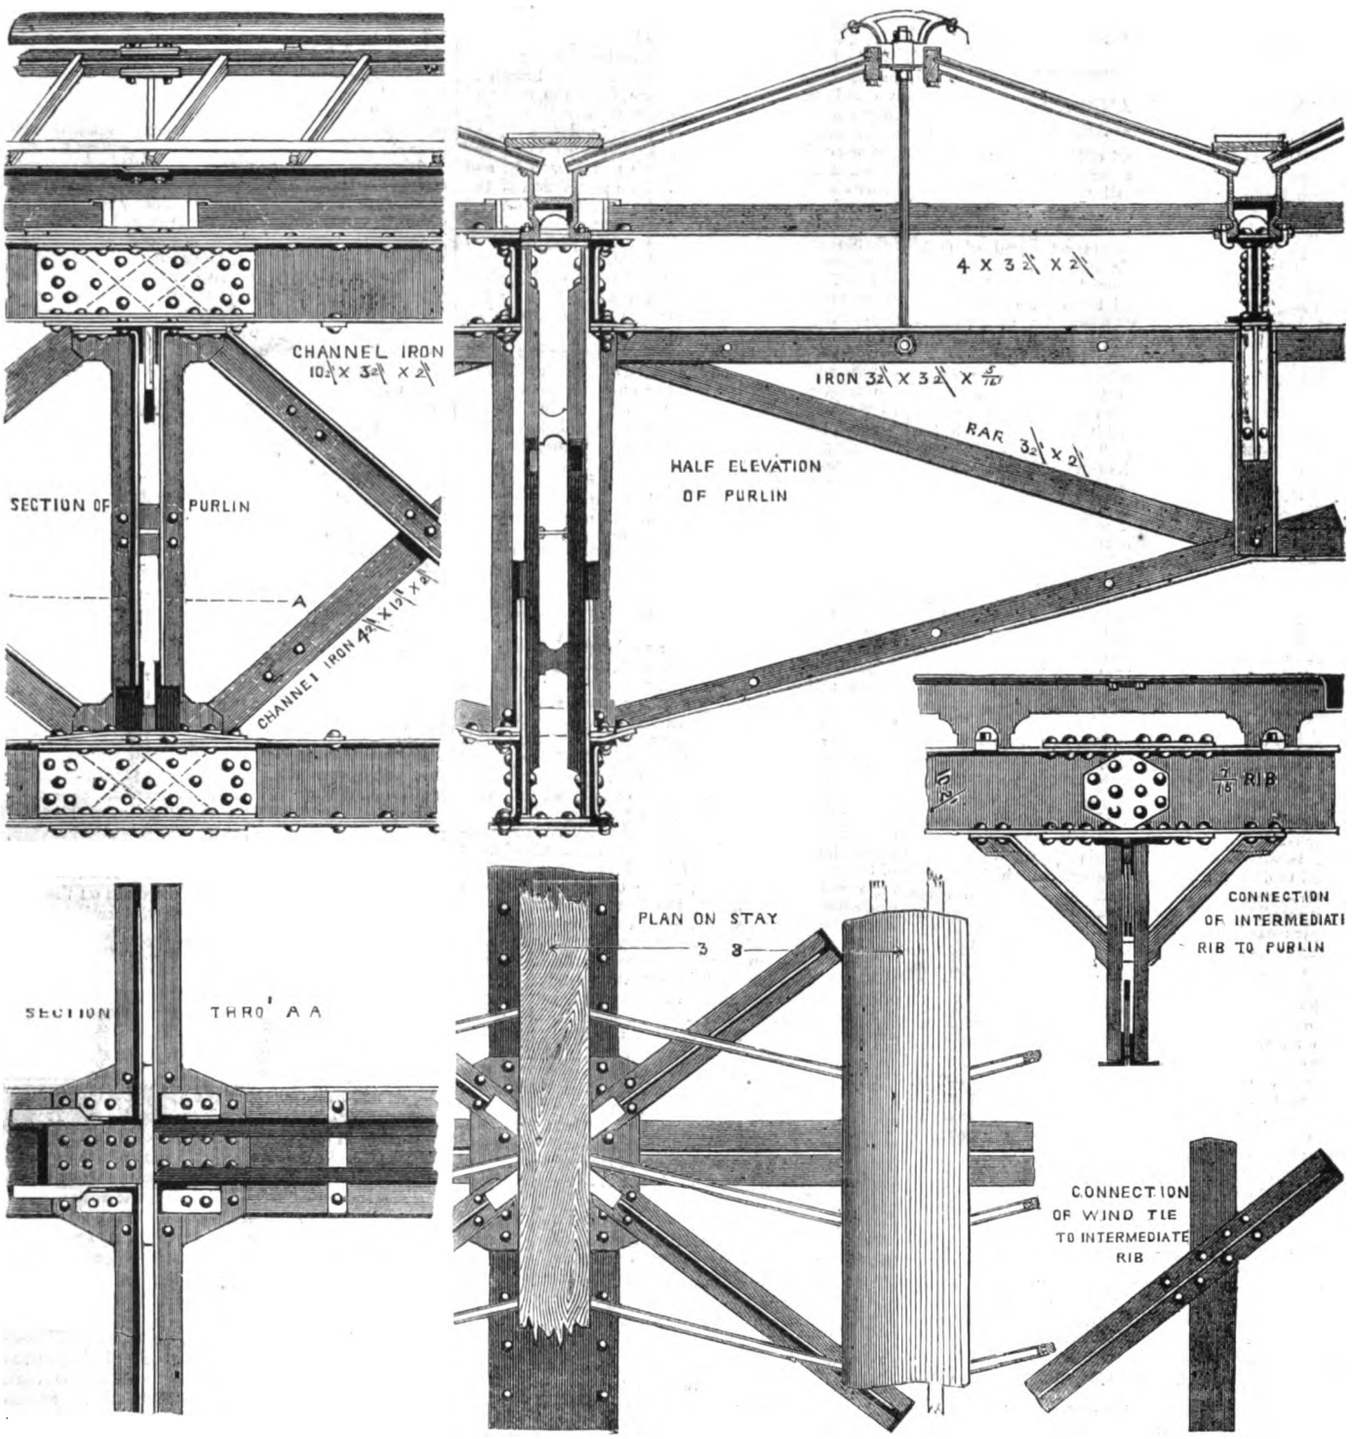
MIDLAND RAILWAY EXTENSION—ST. PANCRAS STATION—DETAILS OF MAIN GIRDERS.

MR. W. F. BARLOW, C.E., F.R.S., ENGINEER.



Digitized by Google

THE ST. PANCRAS STATION, MIDLAND RAILWAY EXTENSION.



THE SAINT PANCRAS STATION, MIDLAND RAILWAY EXTENSION.

WE last week gave the general particulars and drawings of the St. Pancras Terminus of the Midland Railway. According to promise, we now place before our readers some enlarged details of the structure, leaving, however, a few for illustration next week. The springing of each arched rib is composed of plate sides, channel iron, plate flanges, and angle irons, which are riveted to the boxes that rest on the side walls; these boxes are bolted down to anchor plates well built in the walls, by four holding-down bolts 3in. diameter, as shown. At platform level an ornamental casting is fixed, and at the top of the plated portion of the rib, where the lattice work begins, another casting is placed which gives a finish to the springing and an appropriate commencement to the lattice portion of the rib. At the inner face of the wall a handsome ornamental spandril is fixed, which will add to the effect of the roof. The rib is 6ft. deep and the lattice part (distinguished from the springing, which is plated), is composed of channel irons 10in. by 3½in. by ¼in. with flanges 1ft. 4in. by 7-16in., the inner portions of which are connected by distance pieces 2½in. by ⅜in.

The diagonals are formed of channel irons 4½in. by 1½in. by ½in., and are placed in pairs opposite one another at intervals. These diagonals are well braced together by bent plates. Between the main ribs purlins are fixed, which are composed of angle irons 3½in. by 3 in. by 5-16in. in top and bottom flanges, and bars for diagonals 3½in. by ½in., the whole being riveted together form an effectual and strong trussed purlin. The intermediate ribs are fixed on these purlins, and are made of ⊢ iron 10½in. 5½in. by ½in., properly jointed. On these intermediate and main girders are fixed gutters, which carry the skylights, as described in our last impression. Wind ties are riveted to the whole structure, which tend to hold the building together, and prevent the action of storms from doing damage to it. The top of the skylight is capped by a galvanized iron cover.

On either side of the roof, at the ends of the skylights, is fixed a gangway which will be railed in by a light iron railing. This gangway will be convenient for repairs and cleaning out the gutters, &c. The slating of the roof will be laid on boarding 1⅛in. thick, grooved and tongued, and chamfered; the boards will be of best selected Memel, the underside of which will be varnished. The slates will be best Welsh, and each slate will be securely fastened to the boarding with copper nails, weighing about 7lb. per thousand. The lap will not be less than 3in.

The timber work throughout will be well protected by varnishing, painting, or Burnettising, according to the position in which it will ultimately be fixed. The lead for flashings is best milled, weighing about 7lb. per square foot. The glass to skylights to roof is to be of rough plate, 3-16in. thick, well bedded with putty. The holes in the ironwork of the rib are all drilled, and will doubtless come together well. We are, to a certain extent, advocates of drilling all work of this class, as we feel assured that with very little extra cost, a greater synthetic nicety of fitting is obtained, and

Digitized by Google

consequently a much stronger and more durable class of work. It is to be hoped that a very excellent æsthetic effect may be obtained by colour; and as undoubtedly there is the opportunity opened for the use and not the abuse of artistic decoration, we are sure this subject will not be overlooked by the engineer.

EXAMINATION OF AMERICAN BREECH-LOADING ARMS.

THE supplementary report of the board appointed by Governor Fenton for the examination of breech-loading military small arms, has just been published. It will be remembered that in May, 1867, this board, consisting of Brigadier-General George W. Palmer, Commissary-General of Ordnance; Brigadier-General William G. Ward, commanding First Brigade; Colonel George M. Baker, 74th Regiment; and Colonel Silas W. Burt, Assistant Inspector-General, was, on its own recommendation, ordered to make a further test of the Allin, Berdan, and Roberts methods of conversion. The board was also authorized to test such other arms as they considered possessed sufficient merit to entitle them to be admitted for trial. The board met on July 9, and continued its sessions, with intervals, until December 11. The guns submitted for trial were subjected to the following tests, which were prescribed for all the competitors alike:—

1st. For endurance—to be tested with 1,000 rounds, in series of 100 rounds each, discharged rapidly, the arm to be cooled, cleaned, and inspected in the intervals, and the wear and tear, absolute and relative, carefully noted. 2nd. To be fired fifty rounds, with ammunition prepared by the board. 3rd. To be fired with defective cartridges such number of times as the board may deem necessary. 4th. The board reserves the right to subject all the arms to such other practical trials as may be deemed necessary to fully test their merits. The board arrived at the following conclusions regarding the principal guns tested:—

The Allin Gun.—The locking device is secure and easily manipulated. The Miller ejector is disapproved, as the forcible blow of the breech-block upon the lever, as required to eject the cartridge-case, occasions great wear by battering the lever and breech-block, and would probably, after continued use, become inefficient. This ejector was introduced to do away with a spring, which has been hitherto considered undesirable. The board, after very careful consideration, conclude that springs of proper form, material, and workmanship will equal in endurance the other portions of the mechanism. The durability of properly manufactured and inspected springs is demonstrated by those in the lock of the Springfield muzzle-loading arms. No device can secure the exact and constant ejection of the case as well as a spring of the proper elasticity. The question of ejection of the cartridge-case is, however, one dependent upon class of breech system, and in many cases mere retraction is alone necessary. The method of securing the breech-block hinge to the barrel by a band entirely clasping the latter, is a most decided improvement upon the strap merely screwed on.

The Burdan Gun, No. 2.—This gun has no independent locking device for the breech, but depends upon certain nice calculations and analysis of the forces of recoil. As a merely mechanical demonstration, such calculations may be entirely satisfactory, but applied to practice, and relying for their efficiency upon careful manufacture, and delicate adjustments involving exact measurements, they are undesirable. The best evidence of this rests in the fact that the ingenious exhibitor of this gun has presented another upon the system of absolute and separate lock.

The Lamson Gun.—This gun has no independent locking device, and the ability to close the breech and secure it when in position, depends upon a divided breech-block, the relative motion of one portion of which upon the other is equivalent in effect to the loose hinge in Berdan's No. 2 gun. As in that arm, nice adjustments and workmanship are required, nor even then can they be considered as efficient. The guns of this system exhibited to the board have been of beautiful workmanship and unexceptionable material, displaying great mechanical skill; yet at the previous session of the board both the guns exhibited were disabled by the explosion of defective cartridges, and at the present session the breech of the gun, as first exhibited, was blown open by similar cartridges. It was subsequently modified, so as to withstand the test, but it is obvious that a system requiring such nice adjustments is undesirable for military arms. The retractor and ejector of this gun are highly approved by the whole board, and its easy application to the hinge band around the barrel, or to a separate receiver, further commends it.

The Miller Gun.—The locking device of this gun is designed as an equivalent for that of the Allin, the advantages claimed being the possibility of a square recoil seat, and not crowding the cartridge-case forward in opening the breech. Conceding these points, the board does not conceive them as very material, while the sliding movement of the key and consequent friction and wear are certainly disadvantages. If to prevent wear the key is hardened, a violent explosion, as from an imperfect cartridge, may break the key, as was illustrated by the tests. The ejector of this arm has been estimated under the head of the Allin gun.

The Needham Gun.—The lateral movement of the breech-block in opening and closing the breech is a disadvantage as a departure from the unity of movements in vertical planes, and, therefore, being awkward. The locking device is defective, as throwing the whole strain of resistance upon the hammer, and tending to wrench and loosen it, and otherwise derange the lock. The propulsion of the firing pin by the wedging action of the prolonged hammer, is a very inferior substitute for the direct, forcible blow usually attained, and the acquired movement of the pin is very limited.

The Roberts gun was the only gun of this class presented at this session, and it combined many improvements since tested at the previous session. The breech-block and appendages are readily removed and replaced without dismounting the entire gun, as hitherto. A spring has also been applied to the firing-pin, retracting it when not pressed forward by the hammer. The lever should be further depressed, so as to lie closer to the neck of the stock. The strength and safety of this gun, its easy manipulation, and its capabilities for rapid firing, are conceded by the entire board. The security of the breech-block, as against accident by premature explosion, is indubitable. The ejection of the empty cartridge-case is accomplished without springs, as the inclined position of the breech-block facilitates the ejection. Original guns on this system, while embracing all the advantages of the converted gun tested, would also be capable of other important improvements.

The Conroy Gun.—This arm is capable of great rapidity of fire, and the breech, when closed, is strong and safe, the locking being very efficient. The guard-lever movement is somewhat objectionable, for reasons set forth in previous report, but less so than any gun on that principle yet examined. The main and rear spring (both in one) is exposed on the under side of the gun, and, on account of its importance, should be suitably cased. There is no danger to be apprehended from premature explosion of cartridge. The mechanism of the breech is complicated, consisting of many distinct pieces, and most of them exposed when the breech is open. Possessing several good points, those of an objectionable character, combined with the great cost arising from complicated mechanism, would appear to condemn this system for alteration of muzzle-loading arms.

The Remington Gun.—The favourable opinion of this gun, as expressed in a previous report, is reaffirmed. For conversion, the same system as in an original gun is adopted. The substitution of an entirely new lock renders this alteration more expensive than many other systems. The independence of the system in its relations to the remainder of the arm and the compactness of the mechanism are approved. The distinct receiver, as in other guns possessing it, gives an advantage in the substitution of new barrels. The brass case cartridge should be alone used in this system, as the permanent expansion of the copper cases is apt to render the opening of the breech difficult.

The Burton gun was the only one of its class admitted to competition at the present session. The majority of the board estimate it as follows:—Its capability of rapidity of fire is conceded, and also its strength, the efficiency of the retractor, and the probable low cost of alteration. Objection is made:—1. To the sliding movement of the breech-block on account of friction and wear; 2. To the compound motion in opening and closing the breech; 3. To the too facile detachment of breech-block; and 4. To the possibility of a premature explosion of the cartridge, should the firing-pin be jammed in a protruding position. General Ward dissents from the above objections, and esteems this gun, as a whole, superior to any other exhibited, on the score of simplicity, strength, and cheapness. He considers that the loose adjustment of the breech-block, a close fit being unnecessary, and, indeed, injurious, overcomes the first objection of his colleagues; that the compound motion is easy and practically single; and that the construction of the hammer and firing-pin in one piece, and the device controlling its movement, effectually prevent any danger whatever from the last objection. Finally, that in his opinion its extreme simplicity, strength, and ease of repair (there being no small pieces or screws to be lost), commend this system above all others for use in the hands of troops.

After a review of the tests and a dissection and special examination of the several guns, the following resolution, *nem. con.*, was adopted:—Resolved. That after careful and long-continued examination and experiment, and in consideration of the combined qualities of strength, durability, safety, efficiency, and economy, this board deems the Roberts system of conversion of muzzle-loaders into breech-loaders as superior to all others examined, and recommends that the muzzle-loading arms owned by the State be converted into breech-loaders upon the Roberts system. The board also recommend a reduction of calibre in the guns owned by the State by the process known as "re-enforcement" from ·58in. to ·50in.; "but if the increased cost occasioned thereby should endanger the probability of a speedy conversion of the guns, the board advise delay in the reduction of the calibre, as the vast importance of an immediate adoption of the breech-loading system outweighs all other considerations based on minor details."

The report concludes with the following recommendation on the subject of target practice:—The board begs leave, before closing this report, to offer a suggestion as to the expediency of a thorough system of target practice for the National Guard. This exercise, which has gradually fallen into disuse in this country, has been revived abroad, and in England especially has served not only the direct purpose of educating the young men of the nation in the accurate use of arms, but has stimulated martial ardour, and given to the volunteer corps, character, *esprit de corps*, and a world-wide reputation. The laborious winter drills of our National Guard serve an excellent end, but the ultimate purpose of the soldier is the effective use of his weapons, and while we discipline and drill him in all the manœuvres that contemplate him solely as the fraction of a tactical whole, we should not neglect the individual instruction as a marksman, to which all other drill is merely auxiliary, and which alone renders him formidable when detached, and also acting in hostile concert with his fellows. Accuracy of fire is especially desirable in the use of breech-loading arms, as combined with rapidity of fire and long range; it gives this improved weapon the full measure of its extraordinarily destructive power. The English system would furnish the model and general details upon which could be based a system more particularly adapted to our requirements.—"U.S. Army and Navy Journal."

ROYAL GEOGRAPHICAL SOCIETY.

AT the meeting of this Society, on Monday evening, June 8, at Burlington House, the business opened with a paper on a proposed scientific exploration of Central Australia, by Dr. G. Neumayer, late director of the Melbourne Observatory. In this memoir the author described a plan, which he was desirous of carrying out, of exploring nearly the whole of the interior of Australia by an expedition to enter at Port Denison on the east coast, proceed in a south-westerly direction to the centre of the continent near Finke River of Stuart, and thence traverse the unknown western portion by an angular course to Swan River. The expedition was to consist of twenty-five men, including seven professional gentlemen to attend to the various branches of science; and it was to be conducted on a system of establishing a number of depôts, or temporary head-quarters, at intervals of 200 or 300 miles, whence the neighbouring country could be explored in various directions. It was estimated to cost £21,535, and to occupy three and a-half years in its completion; part of the cost, he hoped, would be borne by the Home Government, the Australian colonies supplying the rest. After the reading of the paper, Professor Owen advocated Dr. Neumayer's scheme, in an eloquent speech, on natural history grounds, anticipating great accessions to our knowledge of the peculiar fauna of Australia from so thorough an exploration as that proposed. He thought it not unlikely that some of the colossal marsupial animals known in a fossil state from recent formations might still be living in the unknown interior. Professor Tyndall also took part in the discussion. Mr. Markham's paper was entitled "On the Region between Antalo and the Beshilo, and the Topography of Magdala." He said that the country to the south of the River Tacaze formed an elevated plateau 10,500ft. high, cut through by ravines of enormous depth. From Senafe to Antalo the rocks were almost all sedimentary; but to the southward there is a complete change, and this change is not confined to the geological features of the country; the scenery becomes grander and the vegetation more luxuriant. The bed of the Tacaze was found to be 7,795ft. above the sea-level, and the high plateau of Wadela rises like a lofty wall on a southern bank. After crossing the Tacaze the English troops, instead of marching direct on Magdala, turned off, in a south-west direction, a distance of thirty-four miles over the heights, in order to reach the great road made by King Theodore across the Jita ravine from Wadela to the Talanta plateau. The two plateaux are of the same height, about 9,200ft., were separated by the ravine; and it is evident they once formed a single vast mass of columna basalt, the river Jita, having, in the course of ages, gradually cut its way down to a depth of 3,500ft. Had it not been for King Theodore's marvellous

Digitized by Google

road the English army would have been detained many days by this obstacle. The road was 30ft. wide, and well macadamized: a far more complete work than the roads made by our own men on the line of march. The aspect of this fine road, planned by Theodore and made under his own eye, had great effect in modifying preconceived opinions of his character as a barbarian chief. The Talanta plateau is a flat treeless plain, with a rich black soil, several feet thick. The ravine of the Beshilo is even deeper than that of the Jita; the length of the descent to it was 4 miles 4 furlongs. Beyond it lay the irregular mass of mountains forming the Magdala system. Magdala itself is a mass of columnar basalt with a flat summit, two miles long, by half a mile broad, and 9,050ft. above the level of the sea. The three heights constituting the Magdala system—Selassie, Fahla, and Magdala—form a triangle, and are connected by saddles; to the army approaching from the Beshilo, Magdala was invisible, being hidden by the greater elevation of Selassie. Geologically, the Magdala district formed a portion of the basaltic plateau of Talanta, detached and furrowed by the action of water during vast periods. The climate of the region described in March and April was healthy and agreeable. The difference in temperature between the Wadela and Talanta plateaux was very observable, the latter being much warmer. Mr. Markham gave some interesting details of the last days of the campaign and the end of King Theodore; and, in conclusion, summed up the scientific results of the expedition, which, he said, would prove, when published, of great interest. The country on each side of the line of march had been surveyed by General Phayre and by the Trigonometrical Survey Staff, consisting of Lieutenants Carter, Dummler, and Holdich, with assistants; its geological structure had been investigated by Mr. Blandford; its zoology by Mr. Jesse; and the meteorology by Dr. Cooke.

MANUFACTURE OF ORNAMENTAL METALLIC TUBES.

IN the ordinary manufacture of ornamental metallic tubes a solid brass or other tube of the required thickness is passed through ornamental rolls, and its surface ornamented by the pressure of the rolls. Or a thin ornamental tube made in one piece, or in several pieces produced by rolling or otherwise, is secured by soldering, or brazing, or by collars, to a tubular foundation of iron. Mr. Thomas Weston, of Birmingham, has recently patented some improvements upon this method of manufacture, whereby economy and simplicity of manufacture, combined with strength and durability in the tubes produced, are secured.

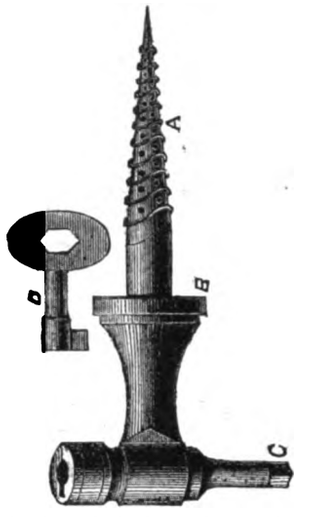
In manufacturing ornamental metallic tubes Mr. Weston proceeds as follows:—He takes a tube or foundation of wrought iron of the required strength, and another tube of thin brass, and by a drawing process, conducted in the ordinary manner, he coats or covers the iron tube with the thin brass tube. The compound tube thus produced is similar to the tubes known as cased tubes. He takes this compound tube and places in its interior a steel mandril, and passes the compound tube supported upon its mandril through ornamental rolls of the ordinary kind, the acting surfaces of the rolls having engraved upon them the pattern it is wished to impress upon the tube. By the pressure to which the compound tube is subjected in its passage through the rolls the outer brass case is impreseed with the pattern upon the rolls, and an ornamental tube is thereby produced. On being removed from the mandril the ornamental tube resembles a solid brass ornamental tube, whereas it is a compound tube, the interior being of iron and the exterior of brass.

A MARBLE RESTAURANT.

A NEW restaurant, of more than ordinary pretentions, to be known as the "Westbourne," has just been opened in Spring-street, Paddington, opposite the departure entrance of the Great Western Railway. According to the "Building News," the building is entirely constructed of different kinds of marble. The wall, in rear of the bar, is covered with coloured marbles of the choicest description. The pilasters which divide this wall into panels or mirrors, are of Spanish jasper marble, with bronze bases and capitals, the whole resting upon a ground of green marble, illuminated with incised lines of gold. Supported by the capitals runs a frieze of bright jasper, with inlaid panels of Vert des Alpes marble, and above this is a bold and massive cornice, carved in figured Bardilla marble, from the centre of which rises an elegant entablature, bearing the name of the proprietor. This entablature is executed in Bardilla and jasper, with panels of Genoa green marbles. At each end of the cornice is arranged a circular pediment, the striking effect of which is heightened by some elaborately carved festoons of flowers in high relief on a rich red ground. The counter or bar is constructed entirely of marble. The plinth, standing upon a tesselated pavement, is of speckled Coquille, and the moulded base of Bardilla marble. The pilasters are of jasper, out of which in the solid block have been wrought circular niches for the reception of bronze figures supporting the cornice. The panels separating these figures are of black marble, inlaid with green and jasper marbles of alternate designs. The frieze or upper part of the panel is also of black marble, relieved by finely cut gilded lines. The cornice is of Bardilla marble, and the counter top of long slabs of the same material, with which correspond the tables and other fittings. The whole of the marble work is polished. It has been executed by Messrs. W. H. Burke and Company, of Warwick House, Regent-street, under the direction of the architect, Mr. A. Evers, of Great Marlborough-street.

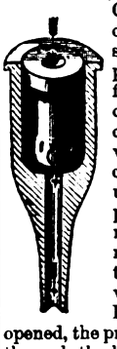
TAP AND VENT VALVE.

OUR attention has recently been called to some useful practical improvements in beer taps and vents—matters of importance at the present season of the year to all who study economy. The tap is known as the Burton tap, and is the invention of Messrs. Atlee and Sons, whose London agents are Messrs. Wheeler and Croucher, of No. 4, Cullum-street, City. This tap, as seen in our engraving, is very safe and economical, being



screwed in through the bung, damage from blows thus being avoided. The screwed part A is passed through the bung to the shoulder B, where there is a leather washer. The outer form of the nose of the tap at C is hexagonal, and the bow of the key D is cut to correspond, and forms a spanner by which the bottom part C is unscrewed and taken off for cleaning. During the process of tapping no liquor can escape, whilst no great strength is required to tap the barrel, a great advantage over the ordinary tap.

The Bourne valve vent, shown in section in the annexed cut, is another of Messrs. Wheeler and Croucher's novelties. This ingenious contrivance is intended for the admission of air into the barrel in such proportion only as is necessary for a free flow of the liquor when being drawn off. It consists of a small hollow plug of wood, one end of which is covered with a cylinder of india-rubber, closed at its lower end, and, at its upper, fastened tightly round the plug. In this cylinder there are a number of fine slits, which, while at rest, are closed, and when subject to any pressure from within the vessel, become still more firmly shut. But whenever the tap or other orifice is opened, the pressure of the air from without passing through the hollow plug, forces the slits open, and so permits the entrance of as much air as may be equivalent in volume to the liquor withdrawn, the slits by their own action resuming their closed condition so soon as the flow of liquor ceases. Placed within a sheath with a tapering end, suitable for insertion in an ordinary spile-hole, this valve forms a most valuable self-acting vent peg, which, from a trial, we believe to be the simplest, cheapest, and most efficacious yet produced.



Messrs. Wheeler have also an improved jar fitted with the vent valve. This application is valuable to the medical profession, as, by its use, infusions and other preparations liable to injury from frequent exposure to air, may be preserved a considerable time without change or any loss of aroma, and be drawn off, as required, by a tap. Medical men often have occasion to recommend special kinds of ale and beer, the best classes of which are only obtainable either bottled or in large casks. By the use of these jars small quantities can now be had, and kept in perfect condition, and drawn off in any quantity without waste.

Whilst overhauling Messrs. Wheeler and Croucher's stock, we noticed a very excellent arrangement of pump for garden and other purposes. It is called the "Standard pump," and possesses the advantage of being easy to work and of not having either leather or india-rubber valves, so that it is unaffected by variations of temperature. The price is low, so that it is at once an economical implement, in addition to which the patentee, Mr. C. W. Orford, claims that it gives the greatest results with the smallest amount of motive power. Mr. Eyles, the superintendent of the Royal Horticultural Society's Gardens, unhesitatingly states that this pump, or hydropult is by far the best he has seen. We may add that the articles above referred to have been patented by their respective inventors.

THE MANUFACTURE OF STEEL RAILS BY HEATON'S PROCESS AT THE LANGLEY MILLS.

ON the 17th of January last there appeared in this journal* an article upon the "Manufacture of Steel Rails by the Use of Oxidizing Salts." Next week a letter was inserted from a gentleman who was thoroughly conversant with what he wrote, claiming that "ever since 1844, Mr. John Heaton, now the managing director of the Langley Mill Steel and Ironworks Company (Limited), has been experimenting with a view to the manufacture of steel by merely removing a portion of the carbon from the pig iron, together with any phosphorus, &c., which it might contain." Aware that the company here named have recently taken steps to considerably extend its operations with a view to the complete carrying out of Mr. Heaton's method, we have been to Langley Mill, and will proceed to state what is going on there with no further preliminary than that what Mr. Heaton claims is the use of the nitrates of soda, potash, and, according to his patent of May 3, 1867, that of the chlorates of soda and potash "to act from the underside upwards upon cast or pig iron, when such iron is in a molten state."

Mr. Heaton, and the company of which he has the practical management, are at work in earnest. A very large sum of money is being expended at Langley Mill, and it is being laid out with much confidence as to the issue, as a result of the experience which the company have already acquired of the worth of Mr. Heaton's method. The works will soon extend over much of four and a-half acres by the side of the Midland line in the Erewash Valley, about nine and a-half miles from Nottingham, and twelve from Derby. The existing capabilities of the establishment are equal to the transforming of 600 tons of pig iron into crude steel in the converters every week. Of this, however, there can be finished only about sixty-five tons of steel and steel-iron in the same period, owing to the incomplete state of the works. But when the furnaces, hammers, mills, and the like, which Mr. Heaton has designed, and which are in course of erection, are ready, the company will be able to treat all the crude metal which they turn out. The cast steel department is on quite an extensive scale. It is divided into two distinct modes of working, designated as the crucible and the reverberatory furnace departments respectively. In the first there are forty-two crucible furnaces, which contain two pots each. Of the forty-two only sixteen are at present in a state to work, the rest are in progress. In the reverberatory department arrangements are being made for four 5-ton furnaces. From these jointly Mr. Heaton will be able to produce nearly 300 tons of cast steel weekly. This side is being worked now upon only a limited scale, extending to not more than one air furnace and six crucible furnaces. The air furnace is constructed on a principle which Mr. Heaton has patented. In the mill department Mr. Heaton is pushing forward operations which contemplate the rolling of railway bars, tires, and boiler plates. For rolling steel of small sizes a guide-mill is being put up. In the tilting department there are two hammers at work, and two of a heavier class nearly ready for use, and a shop is being built for the forging of all kinds of axles. The cast steel side embraces all the appliances for tempering clay and making crucibles; and, when completed, there will not be a finer crucible arch in the kingdom.

The nucleus of the existing establishment was a small ironworks, and in the keeping together of their old connection they make iron for hoops, wire, and

* The "Engineer"

Digitized by Google

tinplates. Nevertheless, only common brands of pig iron are used as a rule in the making of this or any other of the commodities sent away. Still Mr. Heaton's process dispenses altogether with the puddler in the making of steel and iron alike.

The process, as we saw it, consisted in the fusing of pig iron in an ordinary reverberatory, swinging it in a ladle containing about 15cwt. upon a crane and tilting it into a projecting lip of the converter, at the bottom of which was the nitrate of soda, covered with the perforated plate, and held in a waggon cased with firebrick. The lid was clamped down, the gases began to issue, first with a simmering and quickly with a boiling sound, heightening into fierce action till the carbon, which appeared in black smoke at the top of the converter just at the time when the boiling was heard, was nearly consumed in the subsequent flame and sparks which issued from the top of the converter as though impelled by an exceedingly powerful blast, till at length the sodium coming into contact with the oxygen of the atmosphere, a brilliant hue succeeded, which lighted up the surrounding space as with a limelight possessing a slight roseate tinge. All this happened within about five minutes. In that brief time the crude iron has been turned into a valuable refined metal, which, in a creamy mass, fills the waggon before mentioned, and is now rolled away to a convenient spot, where the vessel is overturned and the contents taken in portions to a tilt hammer. Here, instead of spurting and splashing to nothingness, as we had feared, it resisted the steady impact of the tool with a thoroughness which demonstrated its sound metalliferous quality; and it fell at our feet from the tongs of the hammerman with a ring which left no doubt as to what it had become. These cakes of crude metal which, when they are cold, resemble puddled bars cut to lengths of about 10in., are either piled, and, as piles, heated in a mill furnace, taken thence as slabs to the hammerman, and drawn down or rolled as required, or they are broken in the usual manner and assorted for the crucibles—or it may be the contents of the waggons are allowed to cool, and without being placed under the hammer in the first instance, are purified in the ball furnace, and then taken to the hammer like a puddled ball, but only a little less finished than a piled slab. All these different courses are adopted according to the article intended to be produced. And in respect of crucible steel, varieties for charging the crucibles are obtained, Mr. Heaton explained to us, by the different proportion of soda employed, and the brands of pig iron operated upon.

The iron that was being fused when we were at Langley Mill, was half Middlesborough and half Workington; this mixture, Mr. Heaton explained, was an exception, and due to a condition in the negotiations which resulted in the order then under execution.

The method has not yet arrived at that perfection which will permit of an ingot being cast from the converter, but into the larger converters mentioned the iron will run, and not be ladled, from the reverberatory; and the contents of these and of the smaller converters will be placed together in one heating furnace of large dimensions, which has been put up in a contiguous position, and thus rails be rolled off at once.

Steel iron of different sizes was lying in the completed department of the works, and splendid tilted bar tool steel making up completed orders was reared up under cover in the vestibule of the office. All this, with the specimens which were preserved in two cases in the office, and which were shown at the recent quarterly meeting of the iron trade at Middlesborough, had been made of the iron of the last-named neighbourhood. Amongst the finished steel iron in the works, we particularly noticed 2¼-inch rounds for small shafting, and frames for stocking machines, which, if they should be sold at prices even very much under those of the celebrated Yorkshire brand, which was at one time almost exclusively used for these purposes, would yet leave a margin of profit which does not appertain to any transactions in iron or steel produced upon the old methods. The quality was shown in respect of the inch-square, by the fact that it had borne a tensile strain of forty tons, whilst one sample forged when cold—like all the rest shown with it—bent within 3-8in. of touching all over, and other two did not break at all, one touching at the ends, and the other being in the form of a horseshoe. But here we cannot do better than give the following description of Mr. Heaton's specimens, which we take from the "Middlesborough and Stockton Gazette":—

"Deserving of detailed and special mention were two large cases containing steel bars and rods of every description, and steel tools of all kinds, made from Acklam Ironworks' pig iron by Heaton's process. The quality of the iron turned out by Messrs. Stephenson, Jacques, and Co., has long been known to be very superior. But any one who examined what it could be made to do, as shown by the articles in the cases referred to, when put through the patent process of Mr. Heaton, could not fail to have been surprised. Many people supposed that to make steel from Cleveland iron is something new, and is what Mr. Heaton, Mr. Gjers, and Mr. Jones are straining after. What Mr. Jones and Mr. Gjers really aim at is to produce steel from Cleveland pigs at a price that can compete with other large producers, such as Bessemer. Again, steel of a certain quality has long been produced from Cleveland iron, and steel, too, that would make many kinds of edge tools of a certain quality. But what Mr. Heaton aims at, and what he has shown, by his exhibition of Tuesday, he can accomplish, is to make steel capable of being made into turning tools, drills, cold chisels, and other implements requiring an edge of uncommon hardness. These specimens of steel, and tools made from the steel, were manufactured at Langley Mill Steel and Iron Works, Nottingham, all by Heaton's process, and all from iron made at the works of Messrs. Stephenson, Jacques, and Co., Middlesborough. Bars of steel, 2½in. thick, were shown bent double, and which had been bent cold without breaking. Octagon chisel steel, of splendid skin and grain, capable of being made into masons' chisels for cutting granite, and into cold chisels for cutting iron and steel, were shown by Mr. Heaton, or, rather, were shown for him. Screwing dies and taps, and drills, the edges of which, after having been subjected to severe tests in screwing and in boring, showed edges apparently as good as if they had never been used. But perhaps the most notable things on this stall were tools that had been used in cutting chilled rolls, and which had edges about as keen as they could have had before they had torn the parings from the obdurate material on which they had been employed. The turnings from other materials, and which could only have been shaved off with tools of good and durable edge, were shown, the colour on the tools proving that they had not been ground up after having been used. A razor was shown of a fine quality, and which had been in regular use for five months, it only having required stropping during that time. Pit rails were shown bent in all directions, without the least sign of fracture, and steel rods and bars coiled and twisted in every imaginable manner. Files were also exhibited, made also from Acklam Works' iron by Heaton's process, and which presented sharp teeth after having done good service. Hammers, mill bills, and file cutters, were among the numerous articles manufactured from Heaton's steel at Langley Mill Works, from Stephenson and Jacques' pig iron. It will thus be seen that while Cleveland gives promise of becoming the seat of a new industry by the conversion of its pig iron into steel for heavy work, such as rails, tires, &c., there is rich promise afforded in these implements manufactured from Heaton's steel and Acklam pig iron, that Cleveland will be famous as much for quality as for quantity of steel produced. The price of the pigs of which all this was made was probably £2 14s. a ton at Langley Mills."

Langley Mill, a few days before we were there, had been visited by the Duke of Sutherland and other gentlemen, including Mr. Ramsbottom, of the London and North-Western. As illustrating the rapidity with which crucible steel can be produced by Mr. Heaton's process, it was told us that his grace's party took home with them, at four in the afternoon, specimens of finished crucible steel and likewise steel iron which was cold pig iron when the party arrived at the works at eleven the same morning. To produce crucible steel by the old method would occupy between four or five weeks.

No wonder, then, that some of the steel makers who have won fortunes by the old method should be, as we know they are, earnestly looking about them to find out some new plan by which they may continue in the trade without losing the money they have obtained. Here we would remark that it will be found necessary to the speedy realizing of a good profit from any new scheme that the royalties to be charged should be comparatively small. The system we have been noticing, for instance, seems to us to be likely to be taken up on many hands by persons who desire to enter the trade—for it can be adopted on a small scale at an outlay ridiculously small as compared with the expenditure necessary for the carrying on of the Bessemer process; and, next, it can be so easily adapted to blast furnaces that very little difficulty, as it seems to us, would be found in running the contents into converters, and thence following up the process until mills become attached to blast furnaces in much more numerous instances than hitherto, and steel iron and steel become available to the million, and no longer confined, as now, to the few. Mr. Nielson would never have made the money he did out of his hot blast if he had not set his royalty at a comparatively trifling figure. If Mr. Bessemer has got a heavy royalty upon his process, he has been successful because of the wealth of his constituents, and the comparative rarity of the irons they used; but we have little doubt that Mr. Bessemer, if he should succeed in devising a method for utilizing the poorer irons for steel purposes, would quickly adopt a popular tariff, and, in railway phrase, get a better dividend out of the many third than from the few first-class passengers.

Mr. Heaton and his company are evidently looking for royalty returns; for they have patented the process in the United States, France, Belgium, Wurtemburg, Austria, Hungary, Denmark, Sweden, Saxony, Brunswick, and Bavaria; Prussia, Norway, and Russia.

DISPOSAL OF SEWAGE.

MR. R. G. SILLAR, formerly of Shanghai, has just patented an invention which, if the results of preliminary experiments be verified by subsequent performances, will prove at once a most remarkable scientific discovery, an incalculable boon to mankind, and a complete solution of the greatest sanitary problem of the day. By it, says the "London and China Express," the difficulty of disposing of the sewage of our large towns and cities without polluting our streams, is entirely disposed of; and the matter possesses a peculiar interest to our China readers, inasmuch as the discovery is founded on the process so commonly practised there, and so familiar to all who have resided in Shanghai, of purifying the muddy water of the Wong-poo by means of alum. In the course of some experiments based on this use of alum, Mr. Sillar arrived at a combination that is not only capable of clearing thick or dirty water, but which, when added to ordinary sewage or the foulest productions of a drain, at once precipitates all the solid matter, leaving the water pure and clear, while the residuum is perfectly inoffensive and forms a most valuable manure, as the process fixes the ammonia and phosphates that are so important as fertilizing ingredients. Not the least remarkable feature in the process is its marvellous cheapness, as 20,000 gallons of sewage may be purified for about 4s. 6d., while the manure produced is worth about 50s. per ton. In some recent experiments at Tottenham, 35,000 gallons of particularly foul sewage were let into a tank at the rate of 1,000 gallons per minute; even at this rapid rate the process answered perfectly, the solid matter being easily precipitated and deodorized, while the liquid passed off in a state pure enough to satisfy the trustees of the River Lea. An experiment on such a scale as this would seem to put the success of the invention beyond all doubt; and the remedy can be applied with such ease that we may look forward to seeing the Thames and our other rivers very shortly as pure as they were centuries ago, and our towns far more healthy than they have ever been. In a future issue we shall be able to give further particulars of this remarkable process.

Correspondence.

THE PRESENT CONDITION AND FUTURE PROSPECTS OF MACHINE MANUFACTURE IN RUSSIA.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—In following out my line of argument upon the subject I have introduced to your notice, I will now endeavour to prove that the work cut out for mechanical engineers in Russia is even now great enough to furnish full employment for several large factories for years to come. In my first letter, I hinted at the manufacture of locomotives, and stated that Russia during the past three years had ordered from abroad at the rate of 200 per year. There seems to be no appearance of a falling off in this demand. According to the statements of Russian railway engineers, Russia has, compared with such a nation as Prussia, only one-half the necessary number of locomotives for the number of miles of completed railways. This is fully borne out by the continual complaints published in the newspapers of the difficulty of getting goods sent by railway, and by the statements of the immense quantities of grain and other products stored up at different railway stations without means of carriage. As Russia had lately been accustomed to depend almost entirely upon Germany for her supply of rolling stock, the Prussian-Austrian war hindered the execution of orders, whilst the railway companies hastened to open their lines for traffic by the times originally fixed, in order the sooner to receive the benefit of the Government guarantee.

Engineers and directors complain also of the dearness of repairs to rolling stock, and say this increased cost is caused by the want of locomotive factories, where new and spare parts of engines could be easily obtained, and by the necessity of locking up an immense capital in the form of spare articles—capital which they might well employ more profitably. One railway company complains of the fact that it is compelled to keep continually on hand spare parts of locomotives, &c., to the amount of two millions of roubles; and expresses its willingness to pay for such articles, in the event of its being able to depend upon a constant home supply, a higher price than similar articles cost from abroad, and reckons it will yet be a gainer thereby. The cost of repairs seems to increase with the distance of the railways from those places

Digitized by Google

where the few existing factories are congregated and rises very high in the southern districts. Thus the cost of repairs on the Nijigorodskoi Railway is stated to be 7½ kopecks per verst; on the Riga-Dinaburg, 8kop.; on the Warsaw, 11kop.; but on the Odessa-Balta, 22kop.; and the Wolgar-Donskoi, 37kop. Up to the commencement of the present year, no fewer than fourteen locomotive factories in Germany, France, and Belgium, and two in England, had found partial employment in making locomotives for this country; indeed, one or two of the German factories owe their very origin to Russian orders.

I cannot help here remarking, that whereas continental firms have delivered in Russia 848 locomotives, England has only supplied 90. Stephenson has supplied only 50, but Borzig, of Berlin, 250; Sharp and Stewart, 40, but Cail, of Paris, 132. A difference in price cannot be the sole reason for this: it must proceed from an indifference to the wants of the so-called (by Englishmen) Russian barbarians. In Russia itself, in the course of fifteen years, 212 locomotives have been made, and of these the greater number, 190, were made through foreign enterprise and in one factory.

The prospects for the future are:—Russia, to judge by the insufficient number of locomotives at present in use, and from the rapid extension of railways, will require a supply of, at least, 200 locomotives a-year for years to come. Of this number the Imperial Government will require, and, I believe, is willing to guarantee orders for, at least, eighty per year, for five years to come, for railways under its immediate control. Parties interested in the subject say that, to meet this demand, four factories capable of making at first twenty locomotives each per year, ought to be established—one in St. Petersburg, two in the interior of Russia, and one in Odessa. In a short time after the opening of such factories, it is to be expected that private companies would follow the example of Government, and perhaps double the amount of orders. The factories would then have to supply up to forty locomotives a-year each.

The demand for other sorts of machines made necessary by the extension of railways in the south, and the making of which on the spot this very extension will render possible, consists in pumping, hauling, and other engines connected with mining; also for the anticipated ironworks in the great coal and iron basin of the Don. Of the mineral wealth of this part of the country I will speak more fully afterwards; at present, I will only state that the constructor of the railway from Kharkoff to the Sea of Asoph is bound by his contract with the Government to establish somewhere near the line an iron works capable of turning out not less than 8,000 tons of rails annually, and that within a year after the opening of the line.

Independently of all this there are the old established produce manufactures, such as sugar making, distilling, grinding flour, &c., all of which are extensively carried on in this part of the country. Within the compass of a small circle, radiating from the spot where I write, are over forty sugar houses almost exclusively fitted with foreign machinery. The owners of them complain bitterly of the difficulty of getting even repairs done anywhere near, and of the necessity of keeping continually a staff of costly workmen to do work which could be more cheaply executed in a special workshop. They state publicly that if they had in their midst good machine factories, then with the climate and soil nature has given them, they need fear no foreign competition in sugar. Distillers also, under the new excise regulations, have found it greatly to their advantage to grind upon the spot the grain they use, and for this require suitable machinery; whilst, at the same time, the gradual drying up of the rivers and lakes makes grinding for all purposes a very uncertain operation.

It would occupy too much of your space to give full statistics of the increase of these old established manufactures, but we may rest assured that the signs of the times show that with the opening up of the coalfields and the spread of the means of communication, not only will they increase still more, but other manufactures, until now unknown in this part of the country, will spring up and prosper. For instance, this is a great wool growing district; over eighteen million pounds of wool are collected in this town every year; whilst at the same time there is no woollen manufactory in the south of Russia, and in the north none nearer than about 600 miles. One cause of this has hitherto been the dearness of fuel, owing to the scarcity of woods in the sheep breeding district, whilst the abundance of forest land in the north has encouraged the working up of the wool there. Now, however, the tables will be turned; wood fuel is rising very fast in price, whilst coal is to be found under the very fields where the sheep are fed.

To supply this demand for machinery Russia had, in 1864-5, only 108 factories of all kinds connected with the metal trades, Government, railway, and workshops, for the manufacture of tools and domestic articles, all included. These factories produced work to the amount of sixteen and a-half millions of roubles, of which sum, however twenty-nine St. Petersburg factories, including the Government ones, had for their share about thirteen and a-third millions, leaving for the other seventy-nine factories, of which twenty-three were in the Government of Moscow, only 2,279,000 roubles. The factories of all sorts coming under the name of machine factories in the south of Russia produced work to the amount of only 435,352 roubles. Of these 108 factories only fifty-two were driven by steam or water power; all the others had for prime movers either horses or human beings. In 1865-6, the work done had fallen off to twelve millions of roubles; and I do not think that the sum total was much increased in 1866-7, as although there have been some new factories opened, and properly managed ones are prospering, yet the real Russian managed ones are falling back in the race of competition. Through the encouragement given by Government there are now, I believe, four waggon and carriage factories at work in Russia; also four iron works making rails; whilst a fifth, and I might almost say a sixth, are projected. At the same time, Russia purchased from abroad machinery in 1864 to the amount of 7,027,490 roubles, and in 1865 to 6,246,428 roubles; for the nine years preceding 1866, to the amount of 71,629,599 roubles, or nearly eight millions per annum.

Such, then, is a brief and feeble sketch of the prospects of future occupation for mechanical engineers in Russia, and, with your permission, I will continue by attempting to point out in my next communication what, in my opinion, is the proper locality for the future Anglo-Russian engineer colony. It will also, I suppose, be necessary to say something on the all-important question:—Will machine-making pay here? At the same time I hold myself in readiness to answer, as far as I am able, any special questions which may be addressed to me; in fact, if I thought the subject was likely to be taken up seriously, and that my presence would be useful, I would have no hesitation in coming to England to give verbally all the information in my power. I am asked almost every day by some person or other about the probability of foreign manufacturers settling here. I heard yesterday that an English house or houses had taken up the contract for supplying Kharkoff with water and gas; if true, I am very happy to hear it, and would just give them a hint to be very careful what sort of workmen they send here. I have seen several painful examples of the inability of the common English workman to resist the many temptations to be found here, and the want of home influences. The least inclination to drinking will receive a new impulse from many circumstances, and as there is as yet such a distinction between classes here, a man must take care he does not lose caste by making himself on a level with the Russian workman in his cups, as many are liable to do.—I am, Sir, yours, &c., ALEXANDER CAMERON.

Kharkoff, May 11.

[We shall be glad to receive from our readers any comments or questions they may wish to put to Mr. Cameron on the above subject through our columns.—ED. M.M.]

NOTES ON OUR NAVY.

SIR,—I have to thank you for the insertion of my articles on the above; I consider that the subject is exhausted, and never more will men attempt to plunge the country into the ruinous expense which attends the conversion of wood ships into ironclads. My views, with respect to fighting ships, are now becoming general, and I am certain that in a few years they will be built so, and Englishmen may again hope to be predominant on the sea, and, if required, equal the endurance of their forefathers in blockading an enemy's coast. I daily see the efficiency of the many improvements I have suggested, and feel assured that in time they will all be carried out. In a service like the navy, where brains and professional knowledge are often studiously snubbed, one cannot expect to see great changes wrought in a short time, and I am, therefore, content to abide my time. The recent publication of the trials of the Channel squadron fully confirms all that I have long since predicted, and even now stand as if they did not know what class of ship they should next build. It is certain that we shall awake some day from a feeling of apathy with regard to Prussia which now exists, as our eastern seaboard is terribly exposed to a raid from the navy of that growing power. We have ceased to play "Rule Britannia," and have substituted "God Save the Queen" in its place—certainly not a flattering exchange for a martial people. The system of constantly studying to avoid giving offence does not answer either in private or public life. Let a people act correctly, and they may go on regardless of whom they offend. We have but to look at our present relations with the United States to see the truth of this maxim. Does anyone believe that if we had sternly determined to call the American people to account, that a Fenian army would have been allowed to organize itself on our frontier, or regiments to march through New York in all the panoply of war. I know of nothing more humiliating in history, or anything better calculated to distress and worry a high-spirited people. The nation which bought Russian America and St. Thomas, and could not pay for them, is not likely to plunge into a war to protect a set of the vilest assassins that the world has ever produced.—I am, Sir, yours, &c.,

X.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—W. T. B.—R. H. S.—W. M. G.—G. P. C.—J. M.—B. N.—H. D. R.—W. G. C.—R. S.—H. M.—R. B.—S. M.—R. P.—Messrs. B. and W.—T. W. T.—A. C.—R. I.—R. F.—G. W. H.—S. E.—B. B.—J. F.—I. C. E.—W. K.—G. E. Meetings for the Week.

MON.—Royal Institute of British Architects.—The Closing Ordinary General Meeting. Charles Barry, Vice-President, on "The Terra-cotta Work adopted in the New Alleyne College, Dulwich;" Dr. Oppert will give "A Short Description of the Plans of Hospitals at Paris, Munich, and St. Petersburgh," at 8 p.m.

FRI.—Royal United Service Institution.—Colonel Beauchamp Walker, Military Attaché, Berlin, on "The Battle of Koniggratz," at 3 p.m.

Naval, Military, and Gunnery Items.

ADMIRAL SIR W. BOWLES, K.C.B., has resigned the presidentship of the Royal Naval School, New Cross, and Admiral the Hon. Arthur Duncombe, M.P., has consented to be put in nomination.

WE read that a Detroit man is preparing an india-rubber boat, in which he means to "shoot Niagara." The boat will be air-tight, and he will be shut in with twenty minutes' air. Several persons are to be stationed below the Falls to tow the boat to shore.

OWING to some accidents at practice, it is reported that the Snider cartridges are in a state of non-user. Whether the whole are to be condemned or not does not appear, but orders have been issued to suspend the further firing. The declaration of Sir John Pakington, that no pains would be spared to provide the British soldier with the best possible cartridge, does not seem to have borne fruit as yet.

The new telegraphic experiments at the Camp of Chalons have proved quite successful. The dif-

Digitized by Google

ferent commanders of corps are placed in communication with the general-in-chief, who transmits orders to them not alone when the troops are in quarters or on the march, but when they are executing the most rapid and complicated movements.

THE annual reward of cadetships and distribution of medals and prizes took place at the Royal Naval School, New Cross, on Tuesday last. The large schoolroom, in which the ceremony took place, was crowded with visitors, the ladies predominating, and was tastefully decorated with flags, evergreens, and floral devices. Mr. Alfred Eames, the secretary, read the reports of the examiners, and they were highly satisfactory.

A COMPETITIVE examination for appointments in the Royal Navy was held on board the flagship "Victory," in Portsmouth harbour, on Wednesday and Thursday week. Thirteen candidates presented themselves. On Friday, the following names were made known as those of the four successful aspirants for the vacant appointments: — 1. Mr. William Maclean (passed from Eastman's Royal Naval Academy, Southsea); 2. Mr. F. B. Pritchard; 3. Mr. J. G. Matthews; 4. Mr. B. G. L. Evans.

ON Tuesday week, the "Victoria," an iron paddle-wheel steamer, built for the river passenger traffic between St. Lucca and Seville, on the Guadalquivir, Spain, was launched from the building yard of Messrs. Lewis and Stockwell, Blackwall. The vessel is 115ft. long, and will carry about 450 passengers on a light draught of water. She is to be fitted with a pair of oscillating engines by John Penn and Sons, Greenwich, and is expected to attain a speed of fifteen miles an hour.

The "Elk" gunboat, 465 tons, 120-horse power, just completed in her outfit by the Portsmouth steam reserve for her first commission, was put through her light draught trial of speed over the measured mile in Stoke's Bay a few days since, drawing 8ft. 5in. of water at the stern, and 7ft. at the bows. Six runs over the mile with the engines condensing gave her a mean speed of 10·069 knots per hour, and the same number of runs non-condensing gave her a mean speed of 10·137 knots per hour.

SOME changes are about to be made in the uniform of the infantry of the line. The present undress cap will be replaced by a Glengarry, with the regimental distinction on the left side—a change, the "Army and Navy Gazette" ventures to think, of questionable taste. The shell jacket is to be abolished, a Karkee tunic, made after the fashion of a Norfolk jacket, being substituted. The number of buttons on this and the ordinary tunic will be reduced by ten, viz., four on the skirts and three on each arm, from which the present slashing is also to be wiped away.

THE accounts of the Small Arms Factory, Enfield, for the financial year 1866-67 show that there were made in that year and sent into store 17,996 cavalry carbines, Richards' patent breech-loading; 8,160 muskets, smooth bore, with bayonets; 2,480 fusils, ditto; 85,033 musket rifles, pattern 53, converted to breech-loaders on Snider's system; 10,012 short rifles, also converted; and 4,998 naval rifles, ditto. The value or cost of the small arms and implements for small arms sent into store from Enfield in the year is estimated according to several modes of computation; by the lowest it is £187,821, and by the highest £206,420.

THE Defence Committee, consisting of Admiral the Hon. Sir F. Grey, G.C.B.; Major-Gen. Dickens, R.E.; Major-Gen. Simmons, R.E.; Col. Harness, R.E.; Lieut. Ardagh, R.E.; and Mr. J. Hawkshaw, accompanied by Col. Westmacott and Capt. Dolford, R.E., left Moorshead's Hotel, Devonport, on the morning of Wednesday week, at ten o'clock, and crossed Hamoaze by the steam ferry at Torpoint, on a tour of inspection to the westward, visiting in succession the forts, &c., at Screasdon, Tregantle, Raine, and Cawsand, where they embarked on board the steam tender "Bann," which conveyed them to Drake's Island. The next day the committee inspected the forts to the north, including Tamerton, St. Bude, and Crabtree.

ON the day of inspection of the militia in England in 1867 there were present 1,625 officers, 2,986 non-commissioned officers, and 54,225 privates. There were absent with leave 228 officers, 17 non-commissioned officers, and 1,195 privates; and absent without leave 14 officers, 3 noncommissioned officers, and 3,518 privates. In Scotland there were present 234 officers, 429 non-commissioned officers, and 8,232 privates; and there were absent with leave 35 officers and 120 privates, and without leave 2 officers, 1 non-commissioned officer, and 441 privates. The militia in Ireland was not trained in 1867. The establishment of the militia for the United Kingdom is returned as comprising 124,622 privates, but 26,202 were wanting to complete. The largeness of this last number is chiefly caused by the reduction made in 1864 in the effective strength of all regiments whose establishments exceed 600 privates.

Miscellanea.

A COIN of the Roman Emperor Publius Lucinius Gallienus was found in Winchester last week. It was in good preservation.

THE cable across the Straits of Messina, in connection with the direct line between Susa and Alexandria, has been successfully laid.

ONE THOUSAND TWO HUNDRED tons of new potatoes from the Channel Islands and France were imported into Southampton last week.

WE hear that on one of the New Jersey railroads checks may now be obtained beforehand for seats in a train by sending to the station to engage them.

THERE is some talk of repairing the Eagle Tower of Carnarvon Castle, so as to make it available as a museum for the counties of Carnarvon, Anglesey, and Merioneth.

THE explosion of a nitro-glycerine manufactory is reported to have taken place at Stockholm on the afternoon of the 10th inst. Fifteen persons were killed, and a great destruction of property was caused.

THE cross of the Prince Consort Memorial, which is the highest point, has been fixed. The height from the ground is about 190ft. The mosaic work has arrived from Venice, and workmen are fixing it in the places assigned to it.

DURING the rebuilding of the premises of the Institution of Civil Engineers, temporary offices will be occupied at No. 11, Great George-street, where the library will be available for the use of the members, and where the business of the Institution will be conducted.

THE death is announced of Mr. George Newton Browne, secretary to the Midland Railway Company, which took place yesterday week, at Quarn, near Derby. Mr. Brown had been in failing health for a considerable period. He had filled the office of secretary for the past twelve years.

THE coral fishery on the Italian coasts is giving satisfactory results, and this industry annually acquires greater importance. The greater part of the boats employed in this fishery are Italian, and they take to Genoa, Leghorn, and Naples their produce, which forms one of the principal branches of the trade of the peninsula.

THE quickest newspaper telegraph despatch from China was received on Monday last. It contained news of the wreck of the Peninsular and Oriental Company's steamer "Benares." The telegram came from Shanghai by way of China and Russia in nineteen days. The "Benares" was on the China and Japan line. She was 1,491 tons burden, and 400-horse power.

THE Society of Arts have awarded the prize they had offered for the best essay on harvest work and the possibility of artificial aid during it under unpropitious natural circumstances, to Mr. W. A. Gibbs, of Gillwell-park, Sewardstone, N.E. The judges to whom the competing essays were submitted were Messrs. C. S. Read, M.P., C. Wren Hoskyns, and J. C. Morton.

Messrs. Partridge and Cooper, of Fleet-street, have forwarded us a specimen of their new cream-wove club-house paper, which they have manufactured expressly to meet a universally experienced want, *i.e.*, a paper which shall in itself combine a perfectly smooth surface with total freedom from grease. A trial of this paper proves it essentially to possess these peculiarities.

THE annual conversazione of the Royal Institute of British Architects will be held on Wednesday, July 1, next, at the Institute-house, Conduit-street, Hanover-square. Members who have any works of art they may be willing to lend for exhibition on this occasion should at once send particulars to the assistant secretary.

M. NEUMANN, in the Austrian report of the Paris Universal Exhibition in 1867, states that the telegraphic lines in the whole world are 49,255 geographical miles long; there are in Europe 8,000 offices, and 4,000 in the other continents. It has been necessary to employ for the conducting wires 1,300,000cwt. of iron. The expense of establishing all the lines is estimated at 416,000,000f.

AT a meeting of the majority of the curators of the University of Edinburgh, it has been agreed, though not, of course, legally or irrevocably, to appoint Professor Sir James Y. Simpson to the office of Principal of Edinburgh University. This selection, says the "Medical Times," may be, therefore, looked upon as tolerably certain, although the appointment cannot be legally made until the meeting of curators, which will be held in a few days.

THE visitors to the South Kensington Museum during the week ending June 13, 1868, were—On Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 8,442; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 2,001. National Portrait Exhibition, by payment, 2,566; total—13,009. Average of corresponding week in former years, 9,761; total from the opening of the Museum, 7,450,557.

THE corporation of London have paid for rent o Southwark-bridge during about three years and a-half £18,868; and now pay for purchase of the bridge £200,000, making a total of £218,868. The chamberlain handed cheques to the controller for the completion of this purchase on this day week, and, the legal documents being completed, the bridge is now handed over to the corporation, and becomes free for ever for the public use.

THERE has been some delay in the nomination o the royal commission on the military colleges, owing to the difficulty the Government have met with in finding a chairman whose appointment would be likely to be satisfactory to all parties. We, "Imperial Review," learn that the Earl de Grey has now consented to accept the office. Several of the other commissioners are already selected, and the complete list will be published in a few days.

THE "Journal des Connaissances Medicales" states that on January 1, 1868, Europe could boast 102,061 miles of railways; and that, for all the five parts of the world, the grand total is 162,500 miles. This length would be sufficient to encircle our globe twice round the equator, and as many times round a meridian provided with the necessary complement of polar and tropical parallels; and it has taken less than fifty years to form this immense iron girdle, the end of which the next generation is not likely to see.

The Society of Engineers will visit the Chatham Dockyard Extension Works, by permission of the Lords Commissioners of the Admiralty, on Friday, July 3. The council are desirous of making arrangements for the conveyance of the members to Chatham, by steamer, from London Bridge, should a sufficient number signify their intention of joining the party. In order to allow sufficient time for making the necessary arrangements with the steamboat company, members and associates who propose being present are requested to intimate the same to the secretary on or before the 24th inst.

A RAILWAY train brought to a standstill by caterpillars is an unexpected novelty, but such an accident happened to a goods train on the Orleans Railway on the 31st of last month. At one point the road passes through a thick wood, from which the caterpillars issued in such numbers as literally to cover the rails for a considerable distance. The consequence was that the wheels of the engine could not bite, and, after sliding a short distance, the train came to a standstill, and remained so over an hour until assistance came.

LEIPSIC is the centre, as is well known, of a large bookselling trade, producing 8,000 or 10,000 works per annum. In 1867, a bad year, 9,855 works were published. The statistics of the trade show that books on philosophy are less in demand than they used to be, but school books are more so. Treatises on medicine, chemistry, and natural sciences are increasing; jurisprudence the same; less so theology. Languages are more and more in request, as also are history, biography, and memoirs. Novels and light literature are comparatively neglected.

THE "New York Herald" says:—It is manifest, from the extreme length of the letter of the Emperor of China to the President of the United States, that the Chinese carefully graduate the size of their correspondence to the grandeur of its subject and circumstances. The imperial letter from the Brother of the Sun, which was formally presented to the Secretary of State, extended over 25ft. of parchment. No wonder that Mr. Seward could not restrain his delight at the prospect of being called upon by the President to prepare a reply of corresponding length.

THE preparation and arrangements for the forthcoming show of the Royal Agricultural Society, to be held at Leicester, are nearly completed. The portable buildings are erected, and the cattle stalls fixed. The stabling for horses will this year be on a new plan, and the style adopted in Yorkshire will be adopted, instead of having double horse-boxes, but these will be covered with canvas. The turnpikes are to be free of toll during the show-days A very large amount of prizes is offered, and the entries of horned cattle exceed any previous exhibition.

MR. N. B. WARD, the eminent botanist, just deceased, rendered good service to his favourite science by the invention of his closely-glazed cases for the growth of plants. By the introduction of these cases into the dwellings of all classes, Mr. Ward did more than most men to diffuse the love of nature, which was his ruling passion, and by the transports through their agency of valuable plants, as the tea and cinchona into India, he did the State not a little service. Mr. Ward was a fellow of the Royal and Linnæan Societies, and his portrait, painted by subscription, is in the meeting-room of the latter.

THE Committee of Council of Education will be prepared to make grants towards the building of schools of science at the rate of 2s. 6d. per square foot of internal area, up to a maximum of £500 fo-

Digitized by Google

any one school on condition that the school be built under the Public Libraries Acts (13 and 14 Vic., c. 65; 18 and 19 Vic., c. 70; 29 and 30 Vic., c. 114); or be established in connection with a school of art aided by a department building grant; and that the terms of the minute of December 18, 1866 (No. 603), relating to building grants for schools of art, so far as applicable to schools of science, be complied with.

AN exhibition of flowers and plants has been held this week in the gardens of the Royal Horticultural Society. The roses shown were very good, and there were some fine specimens of new varieties of plants now first exhibited. Amongst these were Mr. Bull's areca palm and Mr. Veitch's alocasia antharimon, and the dalechampia rosa—a curious importation from Mexico. Mr. Henderson's bedding plants won the first prize, and Mr. Waterer had a good number of rhododendrons in the special tent. The feature of the exhibition was the variegated pelargoniums, which appear to have thrown some light on the "zoning" of these plants, which has been so disputed a question.

ON the 9th of this month, one of the seals (Phoca vitulina) at the Zoological-gardens, gave birth to a young one, which was at first covered with an abundance of fine silky hair; this, as the animal wriggled about on the ground, was entirely shed, and formed a dense blanket or rug, on which it lay. In less than three hours, says the "Field," the young phoca took to the water, and swam about actively, endeavouring to suck as the mother turned on the side. Unfortunately, however, there was no supply of milk, and the mother has since died in convulsions, since which time the young one has been fed by Mr. Bartlett, on milk and a small portion of cod liver oil, administered by means of a feeding-bottle. The young seal at birth was 32in. long, and weighed 20lb.

A BILL was recently introduced into the Congress of the United States, for the purpose of assimilating the gold currency of the American Union to that of the French system, in pursuance of the resolutions arrived at by the diplomatic monetary conference, held last year in Paris. The measure met with considerable opposition, principally from the commercial community in the United States, as it involved a depreciation of the value of the gold coinage, without providing any compensation for creditors, whose interests would be affected by the change. It appears that this difficulty has now been removed, and that the Bill has been amended so as to secure the adoption by the United States of the international system of coinage which is already in force over so large a portion of the European Continent, without, at the same time, inflicting any injury on the public faith.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3413, 3434, 3459
BUILDINGS AND BUILDING MATERIALS—3428
CHEMISTRY AND PHOTOGRAPHY—3458
CULTIVATION OF THE SOIL, including agricultural implements and machines—3424, 3441
ELECTRICAL APPARATUS—3406
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3394, 3401, 3408, 3411, 3419, 3426, 3432, 3437, 3443, 3444, 3447, 3448, 3452, 3454, 3455
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—3405, 3417, 3461, 3462
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—3396, 3410, 3412, 3431, 3460
GENERAL MACHINERY—3392, 3393, 3395, 3402, 3403, 3423, 3429
LIGHTING, HEATING, AND VENTILATING—3397, 3404, 3415, 3420, 3427, 3451, 3457
METALS, including apparatus for their manufacture—3400, 3440, 3463
MISCELLANEOUS—3414, 3416, 3418, 3430, 3435, 3436, 3442, 3445, 3446, 3449, 3450, 3456, 3464, 3465
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—3398, 3399, 3407, 3422, 3433, 3438
SHIPS AND BOATS, including their fittings—None
STEAM ENGINES—3421, 3425, 3439
WARFARE—3409, 3453

3392 W. C. HOUGHTON. *Certain improvements in apparatus to be employed in connection with hydraulic or other packing presses.* Dated November 29, 1867.

The patentee claims the use and application to "stillages" of hydraulic presses of hollow bars having inclined surfaces at the bottom, upon which other inclined surfaces of plates fitting in such hollow bars act, so as to rise and fall to or from the goods in the stillages of hydraulic presses. Second, in making the other bars of the stillages, as shown in the drawings, so as to reduce the bearing and friction of the movable bars acting against their sides, as described.—Patent completed.

3393 J. H. JOHNSON. *Improvements in machinery or apparatus for grinding bones, ores, and other substances, a part of which improvements is applicable to footstep bearings generally.* (A communication.) Dated November 29, 1867.

This invention relates to improvements in that class of cast-iron grinding mills the cutting and triturating surfaces of which are made in the form, or approximating to the form, of a frustrum of a cone, and consists, first, in constructing the shell and burr of a conical, or nearly conical grinding mill of a number of cast-iron grinding sections fitted and held together, substantially as described, so that the sections can be readily removed to make way for others, the "dress" of the mill being thus rendered changeable to suit the substances to be ground, while the mill itself is more economical both as regards its original construction, and its lasting properties, and the variety of substances which it may be arranged to grind, than mills of the ordinary construction. Second, in a peculiar manner of backing the grinding sections of the shell by an exterior casing, between which and the base to which the casing is secured are confined the said sections, so that the latter can be readily disconnected from the mill. Third, in a mode of securing the cast-iron grinding sections of the burr to a block between a lip or ring or other projection at or near the lower edge of the latter, and a ring fitted to the vertical shaft which carries the burr, all substantially as described, so that the said sections can be readily detached. Fourth, in forming on the ring which aids in securing the grinding sections of the burr grinding teeth, for the purpose described. Fifth, of a certain breaker fitted to and turning with the said vertical shaft, and secured to and rendered detachable therefrom, in the manner set forth, so that different forms of breakers may be applied to the mill. Sixth, of certain detachable sections acting in conjunction with the said breaker for preliminary grinding, the said sections being fitted to and backed by a casing, and held in position by a cup plate secured to the same, and carrying the bearing for the vertical shaft which carries the burr, all as described. Seventh, of a screw and stationary nut, the latter being so connected to the cap plate that, on operating the screw, the casing or backing of the shell, as well as the cup plate, can be elevated (the fastening having been previously detached), allowing the grinding sections of both shell and burr to be removed. Eighth, in interposing between the bottom of the vertical shaft and the bottom of the step in which the shaft turns a double cone of steel, by which the oil is effectually distributed to the bearing surfaces, and the friction is diminished.—Patent completed.

3394 A. TURNER and W. E. NEWTON. *Improvements in the manufacture of carpets, and in warping and preparing warps for the same.* Dated November 29, 1868.

The first part of this invention relates particularly to the manufacture of carpets, and consists of a novel mode of delivering the warp from the warp beams, whereby a uniform length of warp is delivered at every beat up, whatever may be the diameter of the warp beam. The object of the second part of the invention is to produce warps for the manufacture of the piled fabrics in which all the separate threads, more especially those of the ground warp and stuffing, shall be of equal length and tension throughout the whole warp.—Patent completed.

3395 A. V. NEWTON. *An improved method of, and apparatus for, washing or cleansing clothes.* (A communication.) Dated November 29, 1867.

The object of this invention is to provide for a continuous circulation of the water in boilers used for cleansing clothes. To this end the boiler (which may be rectangular or any other suitable shape in plan) is fitted with a perforated false bottom to receive the clothes to be cleansed, and at its sides vertical pipes or passages are provided which communicate with the space below the false bottom, and with the space at the upper part of the boiler, or above the pile of clothes with which the boiler is charged. To allow for the charging of the boiler, it is provided with a removable cover, which may be held in place against internal pressure by any suitable means. Water is admitted to the space below the false bottom, and when the clothes are in place they may be covered in by a loose perforated plate. On the application of heat to the boiler, the water contained therein will be forced up the vertical passages and discharged upon the perforated plate, or upon the clothes, whence it will pass down through the mass and again reach the bottom of the boiler. Here its temperature will be increased, and rising again up the vertical passages will again return through the clothes to the bottom of the boiler.—Patent abandoned.

3396 A. M. CLARK. *Improvements in chronometers.* (A communication.) Dated November 29, 1867.

The patentee claims the application of a bi-metallic ring to the ordinary compensating balance of a chronometer for producing regularity of action under all changes of temperature, the whole arranged in the manner described.—Patent completed.

3397 J. J. PARKES. *Improvements in the means of ventilating rooms and buildings, and in apparatus for the same.* Dated November 29, 1867.

These improvements are chiefly applicable to such houses or buildings as are provided with a circulation of hot water. In carrying out the invention the patentee encloses a tube or series of tubes in a casing forming an air space, and placed above the chamber to be ventilated, the said tube or series of tubes being heated by the hot water circulating through them. The casing is placed in communication with the chamber to be ventilated by means of a tube terminating in a grating placed in the wall of the chamber. The upper end of the outer casing is connected with a pipe leading out into the open air, where it is surmounted by a cowl. The rarefaction of the air surrounding the heated tube or tubes, and contained in the outer casing, causes the air to ascend and escape into the atmosphere by means of the pipe and cowl above mentioned, thus forming a partial vacuum in the pipe below the heated tubes, the air in the chamber being drawn off through the grating to supply its place—thus effecting a continual ventilation of the chamber, so long as the tubes are kept heated.—Patent completed.

3398 W. E. GEDGE. *Improved means of connecting and disconnecting locomotive engines and railway carriages and other vehicles.* (A communication.) Dated November 30, 1867.

This invention is not described apart from the drawings.—Patent completed.

3399 W. E. GEDGE. *An improved brake washer.* (A communication.) Dated November 30, 1867.

The patentee describes this invention as follows:—To secure the constant tightness of a nut, it is sufficient that the washer be always fixed on the object to be tightened up by means of a spur, or otherwise, and that thus the washer be no longer loose around its bolt. The washer being thus fixed, and pressed upon by its nut, any possible rotary movement of this latter will be stopped by raising one of the segments of the washer upright with one side of the nut. This nut is thenceforth a prisoner, can no longer unscrew, and its primitive tightening up is forcibly maintained.—Patent completed.

3400 R. M'CLURE. *Certain improvements in moulds for casting Bessemer steel and other metals.* Dated November 30, 1867.

This invention consists, first, in casing or lining internally such moulds, either entirely or partly, with tubes or plates of wrought iron, cast iron, or steel; and such protective lining may either be applied in the process of casting the mould, or afterwards by forming dovetail grooves in the interior surfaces of the moulds, and keys on the back of the lining plates to slide into them; or any ordinary means may be applied to form the attachment, or the moulds may first be used without the lining, and when burnt by the molten metal in process of casting the lining may be applied, and new linings may be subetituted for old ones as they become destroyed. Second, the improvements consist in the employment and use of detachable or removable lifting loops or ears for such moulds, so that when the lower part of the interior surface becomes destroyed or damaged, the loops may be applied to the opposite end, and the mould reversed, so as to bring the part which was at the lower end to the top.—Patent abandoned.

3401 T. BRIGGS. *Improvements in machinery or apparatus for drying and stretching woven fabrics, paper, or continuous lengths of other similar materials.* Dated November 30, 1867.

This invention consists in arranging, combining, and constructing a series of hollow steam chests in a framing which holds them in the form of a curved volute, or an angled volute; the steam chests are arranged side by side in such form, and have their exterior surfaces slightly convex or curved, with which the fabric is in contact, and a circulation of steam or hot air is maintained throughout by a series of union pipes causing the steam to enter at one end and pass out of the opposite end of the next steam chamber, and so on alternately. At each of the angles a roller is mounted in bearings, and all the rollers are driven from behind by a series of bevel wheels, or other suitable gearing; and if used for stretching purposes, in addition to drying, the surfaces of these rollers are furnished with the points or pins set in a right and left-hand screw-like direction, so as to distend the fabric laterally as they rotate. The back of the machine is enclosed by doors, and a blast or exhaust fan, or other draught-creating apparatus, is applied to remove the vapour arising between the chests during the process of drying. The woven, fabric, paper, cloth, or other material to be dried, is passed, first, on to the uppermost steam chest and over each roller until the end so passed through is folded by a plaiting apparatus in the middle of the volute, and one side only of the fabric comes in contact with the chests or rollers; but if this is not an object, and an extended heating surface is required, rollers may be arranged inside the corners of the volute.—Patent abandoned.

3402 W. STARKEY. *An improved apparatus for obtaining motive power.* Dated November 30, 1867.

This invention is carried out as follows:—Upon a strong framework of wood or iron the patentee mounts three horizontal shafts in the same axial line, and supported so as to be capable of revolving in suitable bearings, an open space being left between the ends of the centre shaft and the inner ends of the outer shaft. On the extremities of the central shaft he keys or otherwise fixes two massive discs or wheels of large diameter, and on the inner ends of the outer shafts he keys or fixes two similar discs or wheels facing the former. On the outer ends of the outer shafts he keys or fixes two balance wheels or driving pulleys, from which the power is to be transmitted by bands or otherwise. Each pair of discs or wheels (that is, one on the end of the central shaft, and the one facing it on the inner end of the outer shaft) is connected together at two diametrically opposite points by two coupling shafts running parallel to the central shafts or axes, and supported in lugs attached to the periphery of the said discs, the lugs and their coupling shafts being so arranged that when those of one pair of discs or wheels are perpendicular to the axis one above the other pair of discs or wheels are horizontal, and in the same horizontal plane as the axes, so that they exactly counterbalance each other. Hung from each of these coupling shafts is a disc or wheel (or a pair of discs or wheels) of smaller diameter than the before-mentioned discs or wheels) so that, as each coupling shaft passes over the centre, the smaller disc or wheel hangs in the space between the two larger discs or wheels above, and clear of the other coupling shaft, which is then at the lowest point below the axis; these smaller discs or wheels are hung from the links, but in shorter links or cranks which are jointed thereto. As each of these smaller discs (or pair of discs) descends by the revolution of the larger discs, it falls into and rolls down a curved or concave way which supports it, taking the weight off the links, and, consequently, off the larger disc or wheel. The impetus which the small disc or wheel gains on descending the curved way carries it partly up an incline on the opposite side of the centre, where it is held by a catch. The other smaller disc on the opposite coupling shaft is at the same time descending, and comes in contact with a lever connected to a massive balance beam above, the other end of which beam is attached by a connecting rod at the outer end of the movable portion of the incline. The movable part of the incline being mounted on a fulcrum at its lower or inner end is tilted up by the action of the beam, and raises the smaller disc still higher, thus keeping its weight off the coupling shaft until the latter has passed over the highest central point of the larger discs, when the smaller disc immediately swings across the space between the two larger ones, and brings its full weight to bear on the descending side of the latter. Thus it will be seen that the weight of each smaller disc or wheel acts upon the descending side in succession, the said weight being taken off the said larger discs, and supported on the concave way and the incline whilst it is being raised on the ascending side, and, hence, there being always a preponderating weight on one side of the axis, the machine will revolve by the action of gravitation, which is confined to one side of the centre only.—Patent completed.

Digitized by Google

3403 W. R. LAKE. *An improved lubricating apparatus.* (A communication.) Dated November 30, 1867.

This invention consists in a lubricator having a transparent reservoir from which the oil is fed automatically upon the journal or other bearing when in motion. This invention is not described in detail apart from the drawings.—Patent completed.

3404 S. E. T. STEANE. *Improvements in globes and glasses for the transmission of artificial and other light.* Dated November 30, 1867.

Here the inventor makes the globe of a double thickness of glass, presenting a convex form both on the outside and inside, and having a hollow space between to contain water or other liquid or fluid for increasing, by its refractive and reflective power, the light encircled by said globe.—Patent abandoned.

3405 W. R. LAKE. *An improved mode of, and means for, clarifying saccharine solutions.* (A communication.) Dated November 30, 1867.

When a solution of raw sugar or molasses has been made in lime water, the inventor employs the neutral sulphate of alumina, by which the colouring and other foreign matter is precipitated and aggregated into a mass that is thrown to the surface by the application of heat, whence it may be removed by skimming, or other appropriate means.—Patent abandoned.

3406 S. SHARROCK. *Improvements in the posts or uprights for electric telegraphs.* Dated November 30, 1867.

This invention relates, under one head, to hollow metal telegraph posts, and consists in strengthening and protecting such posts by using wrought iron or other metal aprons or shorter tubes, ordinarily three or four diameters in length, fitting tightly on the lower ends and joints of the above said metal posts, outside by preference, so as to strengthen and protect such posts at these parts, their usual breaking points, thereby removing the breaking points of such posts further up the posts, where they are proportionately stronger and better able to resist the strain that then comes upon them; they also serve to protect the posts from oxidation considerably above the ground line.—Patent completed.

3407 R. F. COMPTON. *Improvements in couplings for railway waggons.* Dated November 30, 1867.

Here the coupling is effected by means of lever handles arranged at each side of the waggon, and attached to an axis moving in supports at the end of the waggon frame. Upon this axis a lever is mounted near the centre in such a position that, when the axis is caused to make a partial revolution, the lever raises the coupling link, which can then be dropped upon or raised from the hook of the adjoining carriage, and by means of an endwise movement, of which the axis is capable, the coupling link can be moved sideways so as to pass the hook of the adjoining carriage in the act of being raised or lowered.—Patent abandoned.

3408 T., W. W., and J. F. HOLMES, and J. B. and D. LANCASTER. *Improved applications to spinning machinery.* Dated November 30, 1867.

The objects of this invention are to "doff" and afterwards to "fill" with empty bobbins the spindles of spinning frames by a combination of apparatus in lieu of the manual system in use.—Patent abandoned.

3409 R. CLAY. *Improvements in breech-loading firearms.* Dated November 30, 1867.

The patentee claims, first, the stationary cartridge holder or extractor, through the disc of which the striker acts, which disc is supported and held in its required position relatively to the barrel by a metal strap, or by two metal side straps, or by a stem (either solid or hollow) passing through the back of the breech chamber, such cartridge holder or extractor being more especially adapted for use with ordinary central-fire cartridges, and capable of preventing "back flash," in the manner described. Second, the combination with the aforesaid cartridge holder or extractor of the several arrangements of locking tube and parts connected therewith, as described, for the purpose of holding the breech chamber to the barrel as required.—Patent completed.

3410 J. FITTER. *Improvements in the construction and manufacture of mechanism for expanding tables and other expanding furniture.* Dated November 30, 1867.

The patentee claims, first, the construction and addition to the said mechanism of a secondary or supplementary sliding barrel for lengthening the ordinary barrel, so as to make the said ordinary barrel completely cover the screws, substantially as described and illustrated in the drawings. Second, making and fixing the screw boxes or nuts in which the screws of the said mechanism work by casting them in the ends of the screws or barrels of the said mechanism, substantially as described and illustrated in the drawings.—Patent completed.

3411 W. PRIESTLEY and W. BOWER. *Improvements in spinning machinery.* Dated November 30, 1867.

This invention has reference to the production of yarns of a variegated character, that is to say, for example, when it is desired to produce yarns of three or four colours in continuation, or partially in continuation, and partially twisted. To effect this the inventors use what may be termed a double set of back rollers, one pair in front of the others, and they place them parallel to and in proximity with each other; passing, for example, one roving through the back pair of rollers, they pass another through the other pair, and cause the two to meet when they reach the back carrier rollers; and at given periods in the revolutions of the back rollers they cause one or other of the pairs to stand still by means of suitable gearing, the result being that, when, for instance, they stand still alternately, and for equal times, the two supposed colours appear alternately in the yarn and produce a variegated effect, which may be further increased by arranging the gearing so that partially they run alternately and partially together, thus giving a result of "partial continuation" and "partial twist," and, in some cases, two rovings pass through each pair, causing two or more rovings to meet when they meet the carrier rollers.—Patent abandoned.

3412 T. F. WIDENHAM and J. REYNOLDS. *An improvement in the construction of easy chairs, settees, sofas, seats for railway and other carriages, and invalid hospital couches or carriages.* Dated December 2, 1867.

This invention consists, first, in the application of springs coiled at one end, applied by fastening them to the sides of the seat, to the ends of which springs the back is fastened, giving to the same a concentric form, so that when the chair or seat is occupied, the back yields to the pressure put on it, and when unoccupied returns to its original position. Second, with the view to produce the same effect, the inventors use india-rubber, or other elastic material, which is applied by means of bars of wood or metal placed diagonally to the seat, fastened at the front part by hinges or joints, and to which bars the back is fastened. The elastic material is then made to connect the front part of the seat with the back, producing the moving effect as described above.—Patent abandoned.

3413 J. C. WOOLFIELD. *Improvements in boilers for supplying hot water to apparatus for heating buildings.* Dated December 2, 1867.

This boiler may be cleaned internally without disturbing the outer shell, or any of the pipes or other apparatus attached thereto It is formed by an outer shell, and an internal flue tube connected together, or cast in one piece. The union between the shell and flue tube is at the end nearest the fire doors; the flue tube is closed at the end furthest from the fire doors, called by the patentee the "back end;" on the "back end" of the shell is a flange, to which is attached by bolts a lid, and on removing this lid the interior of the boiler may be cleaned. The flue tube is divided into three divisions, namely, first, the ashpit or lowest division; second, the furnace or middle division, which is enclosed by fire doors and contains the grate and deadplate; third, the return flue or highest division which is in direct communication with the funnel or smoke pipe. When of a circular form, the boiler is supposed to be horizontally in a line parallel to its longer axis.—Patent completed.

3414 G. HEIRON. *A method of constructing and combining a castor for pepper, salt, and such like condiments for domestic use.* Dated December 2, 1867.

This castor is divided into two or more compartments, each compartment containing either pepper, salt, or other condiments. The top of the castor is to be perforated, or partly perforated and slotted, or both, round the rim or sides. By this means, not only are the ordinary salt cellars, spoons, and pepper boxes dispensed with, thereby economizing space on the table, but all is protected from dirt.—Patent completed.

3415 E. PRICE. *Improvements in apparatus for regulating the supply of gas to burners.* Dated December 2, 1867.

The object here is to prevent the necessity for daily lighting and extinguishing the public lamps by hand. The apparatus may be constructed of various forms, but the principle of its action is the same—that is to say, that as the pressure of gas is increased during the lighting hours, a bell holder of flexible diaphragm is acted upon and communicates motion to a cock or valve, which is opened thereby, and the gas allowed to pass to the burner, which, when the apparatus is at rest, emits but just enough gas to keep an almost imperceptible flame alight, but when in action allows an ample quantity to give an efficient light. Or the apparatus may be so arranged that, when it is out of action, the flame may be entirely extinguished at the ordinary burner, but as soon as it is put in motion, may be relighted through the intervention of a small supplemental though hidden jet, which is kept constantly burning.—Patent completed.

3416 C. and S. HARGROVE. *An improvement in the manufacture of bells.* Dated December 2, 1867.

This invention relates to the economical production of cast bells. The inventors effect this by the use of carburet of iron and sulphur, the proportions being one hundred parts of Staffordshire, or such other make of iron containing combined or uncombined carbon, and from one-half to five parts of sulphur, varying the amount of sulphur according to the size and tone of the bell to be cast.—Patent abandoned.

3417 W. R. LAKE. *Improvements in the means for filtering syrup in the manufacture of sugar.* (A communication.) Dated December 2, 1867.

The object here is to employ a material for a filtering medium that is not affected by acids or alkalies, and which is practically indestructible, and to arrange it in such a way that it may be cleansed and the deposit removed without taking the filter to pieces. To effect this object the inventor applies asbestos to sugar making as a filtering material, submitting the asbestos in the filter to the action of a current of steam or water flowing in an opposite direction to that taken by the syrup when being filtered, so that the deposit may be washed from the surface upon which it was placed, and removed from the pores of the filtering material in the same relative direction in which it was deposited.—Patent abandoned.

3418 J. H. DEAN. *Improvements in handles for bails, buckets, cove hods, scoops, and the like.* Dated December 2, 1867.

This invention consists, first, in forming the said handles with a straight or cranked centre. Second, in fitting the said straight or cranked part with a rotating centrepiece of wood or metal, or other suitable material; and third, in forming the said handles of metal tapered or reduced in section from the centre to the two extremities, where the handles are attached to the articles to be supported thereby.—Patent abandoned.

3419 W. SCHOFIELD. *Improvements in preparing cloth and yarn to be dyed Turkey red, part of which improvements are applicable to bleaching yarn.* Dated December 2, 1867.

The patentee claims, first, in preparing cloth to be dyed Turkey red, restricting or limiting the quantity of oil with which it is saturated to that required for the subsequent process of mordanting, or as little in excess thereof as practicable. Second, in washing or bleaching yarn, and in preparing yarn to be dyed, and in finishing or cleaning after dyeing, dividing the hanks into portions, and connecting these portions by strings or bands, so as to form the hanks into a continuous chain, whereby yarn may be manipulated with the same facility as piece goods, and a great economy of space in the stove effected. Thirdly, in preparing yarn to be dyed Turkey red, passing the chain of yarn through an oil bath, or working it in the emulsions arising from that mode of preparation, whereby the subsequent processes can be performed without the necessity of exposing the yarn to sunlight and air. And, lastly, preparing and dyeing warps of cotton Turkey red, as described.—Patent completed.

3420 D. BARKER. *Improvements in the construction of chambers for drying artificial fuel and other substances.* Dated December 2, 1867.

Here the outer walls of the chambers are built of bricks, &c., an important principle of the invention being that every part of the fuel, &c., is subjected to the influence of the heat employed, and in provision being made for the continuous exit and removal of the moisture and vapours resulting from the process of drying at the several points from which the same is or are evolved.—Patent completed.

3421 W. BLACK and T. HAWTHORN. *Improvements in valves for steam engines.* Dated December 2, 1867.

The patentees claim so forming and arranging the valves of steam engines when the pressure of the steam is equalized that the steam is supplied to and withdrawn from the cylinder through openings formed through internal cylinders into annular spaces, as shown and described, the advantage of the lap of the ordinary slide being maintained in the piston valve. They also claim rendering cylindrical valves sufficiently steam-tight by means of grooves supplied with a lubricating substance, as shown and described.—Patent completed.

3422 G. PHILCOX. *A new method of shoeing horses.* Dated December 2, 1867.

This invention relates to a permanent shoe and wearing shoe to be fixed on horses' hoofs without nails or screws entering the hoof. The permanent shoe is fixed on the hoof with two bands coming from the hind part of the shoe to the front of the hoof, screwed together with a screw; the shoe is made in two pieces to the shape of the hoof, with a joint to open and close to the shape of the hoof, fixed or held together with an iron plate across the shoe, and two frogs or clips to hold on the front of the hoof. The wearing shoe is screwed on the permanent shoe, and when worn thin can be taken off, the permanent shoe released to pare the hoof if required, and a new one replaced.—Patent abandoned.

3423 R. W. PAGE. *Improvements in the construction of hand garden engines and hydropults.* Dated December 2, 1867.

This invention relates to a garden engine for pumping and forcing water for use by hand, the engine being also useful as a hydropult for extinguishing fire, &c. It consists of a cylinder of brass provided at one end with a stuffing box, through which a piston rod or plunger is made to work, actuated by the right hand of the operator; the other end of the cylinder is fitted to an air globe or vessel, to the opposite side of which an outlet pipe is fixed by a screw or otherwise, in order to cause the water to flow as a jet or stream. The details of the invention are too voluminous to be quoted here.—Patent abandoned.

3424 J. HADLEY. *An improved mode of, and apparatus for, decorticating and drying corn and other grain.* Dated December 2, 1867.

In treating wheat, for example, according to this invention, the patentee first runs it through a wire gauze cylinder of the ordinary construction, to separate therefrom the dust, stones, &c., it may contain, and he then submits it to a damping process. This damping may be effected either by passing the grain through a water bath, or by sprinkling water thereon while the grain is kept in motion by a stirrer, or by a traversing archimedean screw, or otherwise. When the grain is sufficiently and uniformly damped, he submits it to the decorticating and drying apparatus which forms the subject of the present invention. This apparatus may consist of one or more machines, and the form of the apparatus may vary considerably, but in all cases the same character of action will be preserved. The apparatus is not described apart from the drawings.—Patent completed.

3425 G. BREEN. *Improvements in steam winches, which are also applicable to other similar purposes.* (A communication.) Dated December 2, 1867.

This invention relates to a peculiar arrangement of valve box and valve and indicating apparatus to be used in conjunction therewith, and has for its object the facilitating the instantaneous starting, stopping, and reversing of steam winches by the aid of a cheap, simple, and effective arrangement, which is less liable to get out of order than the arrangements hitherto employed for that purpose. According to this invention the seat of the valve which admits the steam or other actuating medium to the working cylinders of the winch is formed with apertures, above which a circular valve is fitted capable of rotary motion. Such valve is provided with an aperture or thoroughfare on one side of its centre, and a cavity or chamber on the diametrically opposite underside of the valve. An indicator and dial are provided, and by turning the printer to one or other of the positions marked on the dial, the motion of the valve is effected, and the winch instantaneously started, stopped, or reversed, as the case may be. Thus, if the indicator be turned to one position, the aperture in the valve will correspond to one of the apertures in the valve seat, and the steam will be admitted through a pipe to one side of the pistons in the cylinders, and the apparatus put in motion; after having acted on the pistons the steam returns by another pipe to the valve box, and passing through the second aperture in the valve seat enters the cavity formed in the underside of the valve, and thence passes through the third aperture in the valve seat into the exhaust pipe, whence it is conveyed into the atmosphere. If the indicator be now turned to another position, the aperture in the valve will correspond to the second aperture in the valve seat, and the steam will be conducted through it to the opposite side of the pistons in the cylinders, and after producing its effect it will be conveyed to the exhaust, and the motion of the winch will be reversed. By turning the indicator to the third position the valve closes the orifice, and the passage of the steam and other actuating medium is instantaneously intercepted.—Patent completed.

3426 J. H. W. BIGGS. *Improvements in apparatus to be used in joining warp ends, which apparatus may also be otherwise applied* Dated December 2, 1867.

Here the inventor employs an apparatus in which the spacing of the threads can easily be corrected, and in which the threads can then be shedded, that is to say, every (say) fourth thread raised or separated from the other threads, so as to be accurately prevented from joining, and with sufficient spaces between them. The old ends are similarly shedded by raising one of the heddles, so that their ends also are presented with suitable spaces between them ready for joining. The joining may be effected either by hand or machinery. There is much detail in the specification.—Patent abandoned.

3427 F. FOSTER. *Improvements in miners' safety lamps, and in the mode of manufacturing the same.* Dated December 2, 1867.

The invention consists, first, in providing existing lamps, or constructing new lamps, in such manner that they carry in, at, or near the roof of the lamp, or in suspending by a projecting spindle or piece or frame above the flame, an extinguisher, which extinguisher is carried on a fusible spindle passing through to the inside of extinguisher, and there held by a nut, which may or may not also be fusible;

Digitized by Google

but if a fusible nut be employed, the use of a fusible spindle is not necessitated. The spindle and nut, or either, or both, are made of any known alloy or composition that will fuse or melt should the temperature exceed a certain degree, and thereby the extinguisher will be instantly set free, and will at once fall over the flame, and by extinguishing it prevent the possibility of explosion. The inventor also provides a guide or guides to insure the accurate descent of the extinguisher upon the flame. Second, in the peculiar construction and application of three concentric rings of metal. The first or outer one has a thread upon its lower exterior surface by which it can be screwed into a corresponding thread in the upper part of fluid reservoir. This ring has at its upper interior surface a shoulder, by means of which the second or middle ring is retained in its proper place. This second ring is provided with perforations or orifices through which the air can flow to feed the flame. The second or middle ring has at its upper inner surface a screw or thread, into which is screwed the third or inner ring, which ring carries the glass of the lamp. This ring is, like the second or middle one, provided with holes or perforations for the admission of air to the flame. Between the outer and middle, and middle and inner rings, are interposed wire gauzes, so that all air entering the lamp by means of the holes in the rings must pass through a double set of wire gauzes before it can reach the flame. Third, in an improved construction of the bottom part of miners' lamps, or that part below the reservoir containing the fluid to be burned. He constructs this part of a metal ring or annular stand having perforations or orifices for the admission of air. This ring is provided with an annular shoulder for the purpose of receiving two diaphragms of wire gauze, which are held in position one above the other by means of a small spring until the bottom is screwed securely in its place. All air entering from the perforations or orifices must pass through the double wire gauze partition formed by the two diaphragms. The diaphragms are bent or made concave, so that there may be an air space between them. Fourth, in the result produced by the peculiar construction described in the second and third parts of this specification. There is double gauze in every part of the lamp, through which air is admitted to the flame, excepting the part where the light has to pass through where the flame is protected by a glass chimney. Fifth, in the mode of manufacturing that part of the lamp forming the reservoir for the fluid to be burned. This, with the exception of the bottom part or floor of reservoir, he prefers to spin up of sheet metal. The bottom part he makes of sheet iron. Sixth, instead of using a tube for the purpose of raising and lowering the wick, he cuts away the lower portion of the tube in such a manner as to leave sufficient metal only in which to cut a longitudinal slot for the purpose of raising and lowering the wick.—Patent adandoned.

3428 R. PORTER. *Improvements in the construction of metallic and other buildings.* Dated December 2, 1867.

This invention has reference, principally, to buildings constructed mainly of metal, and consists, first, of the following method of constructing the walls of the said buildings. The patentee makes the said walls of corrugated sheeting either of iron or zinc, the corrugations being situated vertically, and he supports and strengthens the said wall by means of standards made of metal, rolled or otherwise formed into a trough-like figure. The said standards are fixed against the corrugated walls in such a position that the edges of the said trough-like standards fall into and fit against the bottoms of the corrugations in the walls. The standards may be made of a width proper to include two, three, or more corrugations. Along the interior of the walls, and nearly midway between the floor and roof, he fixes horizontal rails which may be made of wood, iron, or of both combined. The said horizontal rails are supported in brackets connected with the standards, the connection between the said standards and brackets being effected through holes in the corrugated walls. Horizontal rails of the kind described may also be fixed in a similar manner at any required height inside the building. The standards may be fixed inside the building, and the horizontal rails outside where required. The walls may be lined internally with a cheap description of paper board, such as mill boards, straw boards, and the like. He attaches the said lining by making it in sheets or panels which are inserted in rebates or grooves of wood or metal fixed to the walls, or to the horizontal rails. The invention consists, second, of the following method of attaching the ridge caps on the roofs of metallic buildings, and other buildings having corrugated metallic roofs. On the summit of each side of the roof he fixes a strip of hoop iron, which has been corrugated with corrugations similar to those of the roof plates. The said strips of corrugated hoop iron are so fixed on the summits of the sides of the roof that the concavities in the said strips are opposed to the concavities in the roof plates, and there is thus formed a series of nearly circular spaces or openings. The ridge caps are fixed upon the said corrugated strips of hoop iron. There is thus left a series of nearly circular openings along the whole length of the ridge of the roof, by means of which the ventilation of the building is effected.—Patent completed.

3429 W. B. LEACHMAN and J. HOLROYD. *Improved machinery for leather shaving and dressing.* Dated December 2, 1867.

The object here is to cause the knife by which the hide is dressed to accommodate itself to various thicknessess. For this purpose the patentees use a cylinder, hollow or otherwise, mounted on a convenient frame, and of the width of one skin or more, if desired; on this cylinder he makes a notch having a spring catch, to which he attaches one end of the hide or skin; the other end of the hide passing round the cylinder is kept in near contact to the same by friction rollers. On one side of this cylinder, at an angle, say, for instance, of about twenty-eight degrees, they apply the knife. When the skins are tolerably even in thickness they use a fixed knife, that is to say, one fastened to what may be termed the equivalent of a "rest" in a slide lathe, such knife being actuated when needful to cover the breadth of the skin by an ordinary screw and slide rest motion. When they have skins of various thickness to deal with, they employ a roller against the periphery of the cylinder before named, and above that they place the knife with a spring underneath fastened to the fixed rest before named.—Patent completed.

3430 J. H. WILSON. *Improvements applicable to water-closets and pumps connected therewith, which latter improvements are applicable to lift pumps generally.* Dated December 3, 1867.

The patentees claims, first, constructing closet pans or basins of glass. Second, forming the same at the lower end with a shank or hollow faucet, having a lateral opening or aperture therein for discharging the contents thereof, substantially for the purpose and in the manner described and set forth. Third, turning the closet pan on its vertical axis for discharging its contents, substantially for the purpose and in the manner described and set forth. Fourth, constructing closet pans so that they may be removed or lifted from their seats, substantially for the purpose and in the manner described and set forth. Fifth, forming the rotating pan neck or seat of the rotating pan with recesses to receive tallow or other lubricating material. Lastly, the general arrangement and combination of the several parts described and set forth as applied to ships' and other water-closets.—Patent completed.

3431 S. VAILE. *Improvements in tables.* Dated December 3, 1867.

The patentee claims, first, the general arrangement or combination of parts of tables, substantially as described and represented in the drawings, whereby a dining or ordinary table can be converted into a game table, and *vice versa*, or whereby the table top, or a portion of the table top, can be reversed in order that the under side thereof can be made use of, as explained. Second, constructing tables in which one of the rails, or a portion of one of the rails, can be moved out and in, substantially as and for the purpose described.—Patent completed.

3433 J. ECKERSLEY and D. MARTIN. *Improvements in the construction of the permanent way of railways.* Dated December 3, 1867.

These improvements have reference to constructing and securing the joints of rails with the intent and object of cheapening the cost of, as well as doing away with, the bolts, joints, or fish plates, and other similar details at present used, and the invention comprises the following constructions:—An iron chair or bracket is used for each joint, on which there are attached or formed one or more snugs or projections for holding the rails, one or more cushions of wood being placed at the side and underneath the rails. When the rails are put in position they are firmly secured by one or more wedges being slightly bevelled, are drawn tightly into position by a bolt passing longitudinally through the same, and secured by nuts or other contrivance through or into the end of each rail; one or more holes are formed into which pins are inserted that pass into corresponding holes in the bracket or chair. Instead of using loose or separate pins, the projections or snugs on the chair or bracket may be formed with projecting studs which pass into correspondingly formed holes in the rails, so that when the wedge or wedges is or are drawn tightly by the bolt, the studs retain the parts firmly in position, and render their junction very effective.—Patent completed.

3434 J. G. HOPE. *Improvements in utilising mineral and other oils for generating steam, and in the means or apparatus for effecting the same.* Dated December 3, 1867.

Here the firebox of the boiler is fitted with brickwork, or other material, from the front end to the bridge or tube plate up to the level of the dead plate. The firebars are dispensed with, and the top of the brickwork is covered with a slab or slabs of fire-clay, or other suitable material. One or more pipes lead from one or more reservoirs or receptacles containing the oil or oils to be burnt, and pass into the space contained between the slabs and the top of the firebox or flue of the boiler; the ends of the pipes are open or perforated, and the oil or oils pass through the openings in the fire clay or other slabs whereon they are injected. To effect the complete combustion of the oil, and to prevent the formation of smoke, holes are formed in the door of the furnace for the admission of the requisite quantity of air. The holes or openings are provided with covers to regulate the admission of air, according to the quantity of oil at any time being burnt. The oil or oils may be passed through a meter or measuring apparatus, and the flow is regulated by a valve, stop cock, or other means. To increase the draft, and supply hydrogen for the purpose of still further increasing the temperature, a jet or jets of steam may be passed into the furnace.—Patent abandoned.

3435 W. SHAVE. *Improvements in rabbit and vermin traps.* Dated December 3, 1867.

This invention relates more particularly to that class of traps known as the "Dorset trap," and consists in connecting the trigger and plate with the spring direct when setting the trap, in lieu of the separate cross-piece and tongue at present employed for that purpose.—Patent abandoned.

3436 W. PIDDING. *Improvements in placing, arranging, or fixing needles and threads and other like fibrous materials on to reels or receivers so as to render them more convenient for use, also in the manufacture and forms of such reels or receivers, and in the materials thereof.* Dated December 3, 1867.

This invention consists mainly in placing or threading numerous needles on to one length of thread, &c., and after fixing, inserting, or embedding the points of one, two, or more of such needles near to each other into a cushion placed in a hollow formed in and through the centre of such reel or receiver, and then winding in the usual way a layer of thread round it, fixing, inserting, or embedding one, two, or more needles into the cushion placed in the centre at the opposite side of the reel or receiver, and so on, alternately, until the whole of the needles are fixed, inserted, or embedded in the cushion, and the thread they are threaded on is wound round the reel or receiver. In using the thread needles hereinbefore described, the last one, two, or more inserted into the cushion near to each other are removed from it, and those (if any) not placed nearest to the end of the thread are slid along it, and then any required length of thread is cut off for use.—Patent abandoned.

3437 J. THORPE. *Certain improvements in the manufacture of waterproof or liquid-proof paper or glazed paper.* Dated December 3, 1867.

This invention consists in applying to the surface of paper, on one or both sides, a mixture of copal or other varnish (ordinarily used to varnish wood) and linseed oil containing litherage, litharge, or oxide of lead, to produce a superior quality of liquid-proof paper.—Patent completed.

3438 H. F. GARDNER. *Improvements in horses' bits and stirrups.* (A communication.) Dated December 3, 1867.

This bit consists of a curved bar of a circular or other section, extending on each side of the bit from the nose strap, or other portion of the head strap (to which it is attached by a ring), to the mouth of the horse, at which point it is connected to the bit bar by means of a bit through which it passes, and then attached to the bridle rein by a metal loop or ring. A disc or small plate of leather or metal is fixed on each internal side of the bit to protect the horse from injury by the sliding movement of the curved bar in conjunction with the bit bar. The operation of this form of bit allows of the combined bar or snaffle bit and a perfect substitute for the curve bit in one and the same arrangement. The improved stirrup consists in the application to the vertical side bars on the stirrup rest of rollers of metal, wood, vulcanite, ebonite, or other suitable material, and of such diameter as to permit the foot of the rider to pass through the stirrup merely to a sufficient extent to effect the proper bearing of the foot, so that the boot cannot pass through beyond its widest part, which is in front of the instep; in case of the rider being thrown, his foot will be immediately released by the action of the rollers.—Patent abandoned.

3439 W. BROWN and C. N. MAY. *Improvements in portable and other steam engines and boilers.* Dated December 3, 1867.

This invention relates, first, to improvements in portable and other steam engines, by means of which great economy in the consumption of fuel may be effected. It consists of what is commonly known as a "feed water" heater, so constructed that the exhaust steam after leaving the cylinder passes outside the boiler through a pipe which runs alongside nearly its whole length, and is then turned into the smoke-box in the usual way. This steam tube the patentees surround by a jacket through which the cold water is passed, so as to become heated by the steam in the exhaust pipe before passing into the boiler. Below the exhaust pipe, and parallel with it, runs a smaller tube formed in one with the jacket casing, which is placed in communication with the water supply tank, and is for the purpose of returning the heated water thereto when not required in the boiler, together with the condensed steam formed in exhaust pipe. Water is forced through the jacket by means of a pump placed in communication with the supply tank, and driven by the fly wheel of the engine or otherwise. The jacket communicates with the boiler by means of a pipe having a check valve, while the return tube is provided with a stop cock having an index to show its position, which is opened when water is not required in the boiler, so as to allow of its return to the supply tank, and when the pump is working a constant circulation of water in the jacket is maintained, which also warms the water in the supply tank previous to its again passing through the heater. Both the exhaust and return tubes open into the lower part of the blast pipe, an inclined partition or diaphragm being placed across the end of the exhaust pipe to prevent any water of condensation blowing up the chimney with the steam, and to cause it to run back to the supply tank through the return pipe. The jacket is provided with a foot plate for the engine driver to stand on when oiling or otherwise attending to the engine; and it may have circular, longitudinal, or other partitions formed or placed therein to impede the progress of the water and keep it as long as possible in contact with the heated exhaust pipe in the centre. The water may be passed through the heater as many times as required before entering the boiler, but once is generally found sufficient. The second part of the invention consists in strengthening the manholes of boilers as follows:—Instead of riveting a ring around the manhole, as usual, thereby increasing the thickness at that part, they cut the hole smaller than is required, and force a die through it, which raises the edge of the plate. This raised lip or flange may either be turned down or left projecting, the object being to strengthen the boiler at the manhole, the reverse effect being produced by riveting on a ring, as in ordinary.—Patent completed.

3440 J. GJERS. *Certain improvements in the manufacture of cast steel and homogeneous iron.* Dated December 3, 1867.

Here, when crude iron or refined iron is caused through the action of iron cinder, or other additional matter, to boil and to come to nature, the patentee transfers the material under treatment from the puddling, or other equivalent furnace, even before the process of balling, and by remelting, fluidifying, or keeping fluid such material, he causes it to separate from the cinder and to attain an uniform quality ready to run into ingots. Thus, he melts crude pig iron, or refined iron, or recarbonized puddled iron, and works it in the usual way in a puddling furnace, and causes it, through the action of rich pure iron cinder, or other additional matter commonly used when making puddled steel (for instance, as manganese and salt), to boil and to come to nature in the manner adopted for making puddled steel or puddled iron.—Patent completed.

3441 R. HORNSBY and J. E. PHILLIPS. *Improvements in reaping and mowing machines.* Dated December 3, 1867.

In constructing a reaping and mowing machine the patentees mount the axis of the pinion gearing with the ring of teeth on the main carrying wheel, and also the axis of the crank which drives the knife on a cast frame which pivots on the axis of the carrying wheel on its inner side, or between it and the cutters. This frame also has the finger bar fixed to it. The driver's seat is supported from the axis of the main carrying wheel, and from the shafts, so that the finger bar can rise and fall altogether independently of the driver's seat, and, consequently, the finger bar runs very lightly over the land. The finger bar is lifted and adjusted to the height required by a chain connected with the cast frame already mentioned, and passing to a lever jointed to the shafts. At its other end this lever drops between teeth or stops formed for it on the side of the support of the driver's seat.—Patent completed.

3442 W. SANGSTER. *Improvements in umbrellas.* Dated December 3, 1867.

Here the inventor forms a gutter around the umbrella just above the curves at the edge by fastening a band of india-rubber fabric, or other fabric, by one edge to the umbrella in such manner that, when the umbrella is open, its other or free edge stands off from the umbrella all round, and inclines upwards, so as to form the gutter required.—Patent abandoned.

3443 N. GREW. *Improvements in apparatus for cleaning or decorticating cotton seed and other grains or seeds.* Dated December 3, 1867.

This invention is not described apart from the drawings.—Patent completed.

3444 F. R. ENSOR. *Improvements in the manufacture of lace in twist lace machines.* Dated December 3, 1867.

This invention is not described apart from the drawings.—Patent completed.

Digitized by Google

3445 C. PALEY. *An improved elastic material to be used as springs in boots and shoes, and in various other ways to which the same may be applicable.* Dated December 4, 1867.

One part of this invention consists in manufacturing an elastic material by means of a sheet of india-rubber placed between either two pieces of leather, or any other suitable materials, the colour and description of either of which, as also the strength of the spring, can be varied according to circumstances. Another part of this invention consists in inserting these springs in certain parts of boots and shoes in a manner similar to those now in use, and otherwise.—Patent completed.

3446 J. SANDERS. *Improvements in braces for supporting articles of dress.* Dated December 4, 1867.

The inventor employs two straps or bands passing over the shoulders in the ordinary manner, the back ends being connected together by a stud or otherwise. To each of the buckles by which the braces are lengthened in front he attaches a small frame carrying a pulley or roller, and over the said pulley or roller the catgut or band carrying the tabs or brace ends passes. At the junction of the braces at the back he also attaches a frame carrying a pulley or roller, over which a catgut or band having tabs at its ends passes. In wearing the braces the several tabs at back and front are connected by means of the buttonholes in them to the buttons of the trousers or article of dress. When, by the inclination of the body, a great strain is put upon either of the tabs, the catgut, or band it is connected with travels over the pulley it bears upon, and the strain is immediately distributed over both the tabs, instead of being borne by one only. The distribution of strain described takes place at the tabs at the back, as well as at those in front of the wearer.—Patent abandoned.

3447 T., G. B., and B. STEPHENSON. *An improved mode of waxing warps in the process of weaving.* Dated December 4, 1867.

The patentees employ a roller made of wax of any convenient diameter, and of sufficient breadth to cross the loom beam. This roller they place in the back part of the loom in such a position horizontally that all the threads of the warp pass over it, and, consequently, are uniformly waxed. The position it is preferred to place the rod in is to rest upon the warp as it unfolds from the beam, and thus by its own gravity to bring about the desired effect.—Patent completed.

3448 J. NEWTON. *Self-acting radial doffing knife or comb motion.* Dated December 4, 1867.

It has hitherto been difficult in the machinery referred to in the title (which has special application to tow or jute machinery) to give proper oil or lubrication to the axle of the doffing knife, and the eccentric in connection with it. The difficulty arose from the fact of the doffing knife requiring oiling or lubricating once in every three hours, or thereabouts. To obviate this defect is the object of this invention, and for this purpose the inventor places upon the end of the doffing-knife shaft a quadrant; he secures to it another smaller quadrant by means of bolts and screws in the ordinary manner. In connection with that smaller quadrant he places a small longitudinal and horizontal tube made of wrought iron, or any other convenient metal, and this being bored or hollow, as the case may be, is capable of receiving oil or lubricating mixture from a point near its extreme end, as well as from the end nearest the doffing-knife shaft or comb by means of suitable cups. Upon its being charged, and, in consequence of its communication with the doffer or knife shaft, and a further small passage being made to the eccentric shaft, which is generally surrounded with bearings of hard wood, he is enabled to give the necessary lubrication for (say) generally about three days' supply.—Patent abandoned.

3449 R. M. LETCHFORD. *Improvements in circular boxes for the purpose of abstracting their contents without removing the lid or cover.* Dated December 4, 1867.

The boxes to which this invention is particularly applicable are the boxes in which cachou aromatise are kept. In carrying out the invention the patentee cuts, punches, or otherwise makes an opening or aperture of any desired size or shape in the side of the rim of the cover of the box, and he also cuts or otherwise makes a corresponding opening or aperture in the rim of the body of the box, but by preference twice the width of the opening or aperture in the side of the cover. It will now be understood that when the cover is on the box, and the openings or apertures in different positions or places, the contents will remain in the box, but when the lid or cover is moved round until the holes are brought opposite each other, the pilules or other like contents of the box will fall out slowly and gradually. When sufficient for the time being has been extracted, the lid or cover can be moved round and the contents secured.—Patent completed.

3450 R. R. GRAY. *Improvements in metallic casks or vessels.* Dated December 4, 1867.

This invention is not described apart from the drawings.—Patent completed.

3451 E. T. HUGHES. *An improved lighting, heating, and cooking apparatus, part of which is applicable to other purposes.* (A communication.) Dated December 4, 1867.

This apparatus consists of a stand of suitable size and form, on which is placed a hollow vessel for containing petroleum, or other hydrocarbon oil, the said oil being supplied to the hollow vessel through a hole closed by a screwed-up cap. On the top of this oil vessel are fixed one, two, or more burners, according to requirement, in which are placed felt wicks, which wicks are raised and lowered by pinions turned by hand, or in any well-known manner. On the top of the oil vessel are three or more projections, on which is placed the heating chamber, the spaces between the said projections allowing air to pass into the heating chamber with the flame of the lamp, and thus assist combustion. The heating chamber is made of metal, and has a perforated metallic diaphragm at its base for the admission of air, the said diaphragm being provided with slots through which pass the burners, and with projections corresponding with those on the oil vessel, into which they fit, thus keeping the heating chamber securely in position. In the interior of the heating chamber is placed a strong metal plate, also provided with slots corresponding to the size and number of burners, the said slots being cut or cast in projections on the said plate, which serve as chimneys, and into which the burners pass. Near the top end of the heating chamber is a grid, on which can be placed small vessels containing the food or liquid to be heated or cooked, and the top of the heating chamber is provided with projections on which can be placed larger vessels containing the food or liquid to be heated or cooked. At any convenient point in the heating chamber is an aperture over which is fixed talc, or other transparent non-fusible material, so that the state of the flame may be observed therethrough, and the wicks raised or lowered according to requirement. A plate of metal or other material is placed over the grid, which aids the consumption of the smoke or gases issuing from the flame, thereby preventing all smell arising from the apparatus. Felt wicks can also be applied to any other description of petroleum lamp now in use.—Patent completed.

3452 F. B. BAKER and L. LINDLEY. *Improvements in ornamenting lace and other textile fabrics.* Dated December 4, 1867.

The inventors employ seeds of various kinds, and globular and other shaped ornaments, made of compositions of sugar, plaster of Paris, or other suitable material, and paper cut or stamped out to any desired pattern, such materials being suitably dyed, stained, or coated with a composition of the colour desired. Or, in the case of paper, it may be embossed and printed to any desired pattern and colours. Ornaments of the character above mentioned the inventors apply to lace and other textile fabrics by dipping them in gum, or other suitable adhesive material, or by applying gum or other suitable adhesive material to the back thereof, and then placing them in position on the textile fabric to be ornamented in any desired pattern.—Patent abandoned.

3453 E. WALKER. *Improvements in the construction of breech-loading ordnance.* Dated December 4, 1867.

The patentee claims the construction of breech-loading ordnance by the application to a fixed barrel of a series of horizontal rotating chambers, turned either by manual power, or by a lever, and tightened or jammed against and in line with the fixed barrel ready for discharge by means of a vertical eccentric axis, operated by a lever, and released from such barrel after discharge by the same means, substantially as described.—Patent completed.

3454 F. JOLLY. *Improvements in machinery for clamping and stretching woven fabrics.* Dated December 4, 1867.

This invention consists in the employment of rollers working in conjunction with travelling bands, between which two parts of the cambric to be clamped and stretched pass, and in such manner that the fabric gradually leaves the detaining bands so as to allow the stretching to extend to the selvage. For this purpose the inventor proposes to employ the flanged rollers, the axes of which are placed at an angle to each other. Against these flanges the fabric to be stretched is clamped by travelling bands, which he proposes to pass over rollers, and to provide with a weight for giving the necessary tension. He proposes to drive the flanged pulleys by toothed wheels in gear with projecting pins.—Patent abandoned.

6455 J. T. WEBSTER and W. OXLEY. *Improvements in machinery for spinning and doubling fibrous materials.* Dated December 4, 1867.

This invention consists in an arrangement whereby the drag necessary for spinning and doubling is obtained, and in such manner that it can be varied in amount as required. The spindle is placed within a tube to which it is connected by a pin and slot, and its lower part is provided with a flange having an inclined surface. Upon this a circular plate rests, carried by a collar, within which is a boss surrounding the spindle, but of larger diameter. This boss may therefore be moved backward or forward by an eccentric or similar means, so that the aforesaid plate may be caused to bear upon the inclined flange at different distances from its centre of motion, the drag being thus capable of variation.—Patent abandoned.

3456 J. F. CLARKE. *Improvements in means and apparatus to be applied for melting snow and ice in public thoroughfares, or otherwise.* Dated December 4, 1867.

This invention consists in the employment of a blast of air in combination with a jet or jets of gas in ignition, as described.—Patent completed.

3457 W. A. HERRING. *Improvements in apparatus for warming buildings in which high pressure steam engines are employed.* Dated December 4, 1867.

Here the patentee causes the exhaust steam from the engine to pass a coil of pipe of such diameter that the back pressure on the engine may be insignificant. This coil he encloses in a cistern or close tank with which pipes for warming the building are connected. The outlet pipe passes away from the top of the cistern or tank, then circulates through the rooms or buildings to be warmed, in the ordinary way of a hot water apparatus, and afterwards the pipe returns the same water in a comparatively cold state to the bottom of the cistern or tank. This water remains in the cistern or tank until it again becomes hot, and then it again circulates through the pipes of the hot water apparatus. In this way the rooms or buildings are warmed without other fuel than than that necessary to keep the high pressure steam engine at work, and at the same time an economy of water is effected, which sometimes is of importance, the exhaust steam from the engine being condensed into a pure water which is returned into the boiler.—Patent completed.

3458 J. H. JOHNSON. *Improvements in the production of materials suitable for blasting and other similar purposes.* (A communication.) Dated December 5, 1867.

Here, according to one modification, the nitro-glycerine is mixed with a porous combustible substance, such, for example, as finely divided wood charcoal, which, by preference, has been previously saturated with a solution of saltpetre, or nitrate of soda, or mixtures of the same, and also with a solution of carbonate of soda, and subsequently dried, so as to expel the water employed for effecting such solution.—Patent abandoned.

3459 D. SMITH. *Improvements in steam boiler furnaces, and in apparatus connected therewith.* Dated December 5, 1867.

This invention consists in placing within the furnace of steam boilers a retort or chamber made of metal, fireclay, or other similar substances. This retort is closed at one end, and has an opening or openings in its side or sides. The fire grate is placed below the retort, so as to receive the gases generated in the retort. Coal or common slack is thrown into the retort, which, when heated, details over the gases contained in the coal or slack; the gases then pass through the opening or openings in the retort, and are consumed in the fire under the retort, which, to a great extent, will prevent dark-coloured smoke from passing up the chimney. An aperture for the admission of air is made in front of the furnace with a sliding door, so that the quantity of air passing into the furnace to support combustion may be controlled by the fireman.—Patent abandoned.

3460 S. L. WORTH. *Improvements in step chairs, ladders, and steps.* Dated December 5, 1867.

The seats of these chairs are usually cut across parallel with the front, and jointed with hinges, the said cut being carried on both sides down to bottom of back leg. The back part of chair being thrown over the front, forms steps for libraries, halls, and other purposes. Now this invention consists in placing a locking bar from the front leg to the back, which secures the chair; or when turned over, and used as steps, the said bar turns the opposite way, fastening on the back of the chair and keeping the steps perfectly secure. The inventor also places a handrail in an upright position, which can be turned down, forming part of the top step when used as a chair.—Patent abandoned.

3461 J. GREEN. *Improvements in machinery or apparatus for cutting or breaking sugar.* Dated December 5, 1867.

This invention consists in the application of a self-acting feed apparatus to ordinary machines employed for cutting or breaking lump sugar into small pieces. This feed apparatus consists of two grooved rollers, mounted in suitable framing, one on each side of the cutting block or bed upon which the knife acts, and an endless cord or band passing around the two said rollers in a series of coils, embedded in the said grooves, thus forming an endless apron which is caused to travel or move intermittently by means of a ratchet wheel fixed on the end of one of the rollers, operated by a pawl or catch lever connected by a rod to the ordinary cutting knife, so that, after each stroke of the knife, or in its upward movement, the ratchet is operated, thereby turning the roller, and, consequently, the cord or apron is moved forward a suitable distance, according to the arrangement of the ratchet and lever, which are capable of adjustment as required. A self-adapting spring pin or holder is also attached to the ordinary knife frame, which strikes upon the sugar on the fall of the said knife to hold the sugar during the cutting or breaking thereof, and notches are also formed in the bed to receive the cords and prevent them being cut by the action thereon of the knife.—Patent abandoned.

3462 J. MABSON. *Improvements in bags for coffee and other pots.* Dated December 5, 1867.

This invention consists in attaching a float to the bags used for containing coffee, tea, or other material in pots in which an infusion or extract is to be made, so that the bag is always suspended from about the level of the surface of the liquid in the pot. In carrying out the invention the patentee takes a tube or float of annular or other form, and he hinges to its lower side a bag of wire gauze, or other suitable material; the float has a catch diametrically opposite the hinge to secure the other side of the bag when in place. The upper or lower side of the float may be covered with wire gauze, or other suitable material.—Patent completed.

3463 S. PERKINS and W. SMELLIE. *Improvements in the manufacture of malleable metal of a steely quality, partly from Bessemer scrap or other Bessemer metal.* Dated December 5, 1867.

The patentees claim the manufacture of metal having a steely quality, by melting scrap or other steel with common pig iron in a cupola or other melting furnace, and adding to the mixture thus produced more common pig iron, and puddling the same in a puddling furnace, substantially as described.—Patent completed.

3464 J. G. SCOTT. *An improved means to be employed for effecting the safe transmission of money or money orders, whereby the present system of book-keeping in connection with such transactions is avoided and the possibility of fraud prevented; also improvements in the formation of documents that have to be separated.* Dated December 5, 1867.

Reference to the drawings is essential to a full description of this invention.—Patent completed.

3465 J. ADAMS. *Improvements in apparatus for dating railway and other tickets.* Dated December 5, 1867.

This invention consists of an improved machine or apparatus for printing or stamping the dates upon railway or other tickets as they are issued, which may be used either for printing the date with ink in ordinary type, or for stamping or impressing the date either with or without ink by steel type. The machine is of the same character as the ordinary dating machine, in so far as that the pressing of the ticket into a mouthpiece brings down the type and gives the impression, the inking of the type (when ink is used), being also self-acting on the withdrawal of the dated ticket. The mouthpiece is supported and swings upon two links mounted on pivots beneath, and has an arm projecting from its rear side which is jointed to a bent lever, keyed or otherwise fixed on a rocking shaft, the said shaft being supported in suitable bearings. Upon the rocking shaft is also secured another lever, the outer end of which is joined to a vertical type carrier in such a manner that, when the mouthpiece is pressed inwards, the type carrier is brought down to give the impression. The type carrier is kept always perpendicular by a parallel link attached to its upper end. The inking pad swings upon pivots, and is connected by a link to the bent lever, so that when the mouthpiece is pressed inwards, and the type carrier is brought down, the inking pad is drawn out of the way; but as the type carrier rises, the inking pad is raised also, and pressed against the face of the type. A spring or other equivalent contrivance is connected to the rocking shaft or other movable part of the machine to bring the apparatus into the last described position on the withdrawal of the dated ticket.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated April 4, 1868.

1139 F. A. Calvert, Manchester, engineer. Improvements in machinery for cleaning and preparing cotton and other fibrous substances; also for selecting the long from the short fibres, and for opening twisted yarns and woven fabrics.

Dated April 11, 1868.

1208 J. C. Wilson, Lime-street, City, civil engineer Improvements in hydraulic packing presses.

Dated April 16, 1868.

1250 J. H. Johnson, Lincoln's Inn-fields, Middlesex. Improvements in heating and ventilating, and in apparatus employed therein. (A communication.)

Dated April 22, 1868.

1310 R. Side, Southwark Bridge-road, Southwark, Surrey. A new machine for obtaining motive power.

Dated May 5, 1868.

1458 D. P. Wright, Birmingham, lamp manufacturer. Improvements in the method of and means or apparatus for pouring, drawing off, measuring, and regulating the flow of liquids.

Dated May 13, 1868.

1563 H. B. and A. Mullord, manufacturing stationers, Horton, Middlesex. Improved materials for the manufacture or ornamentation of bonnets and other articles.

Dated May 14, 1868.

1578 J. Dewar, doctor of medicine, Kirkcaldy, Fifeshire. Improvements in preserving certain vegetable substances for use as food for animals.

1583 W. A. Brown, Victoria-road, Peckham, Surrey, and R. L. Jones, Edgware-road, Middlesex, civil engineer. An improved hand signal lamp.

1586 W. Walker, East Cross-causeway, Edinburgh, engineer. Improvements in the processes of cutting and dressing millstones, and in apparatus to be employed for such purpose.

Dated May 15, 1868.

1589 T. J. Gathercole, High-street, Homerton, Middlesex, engineer, and T. R. Comyn, Raleigh House, Mare-street, Hackney, Middlesex. Improvements in the construction of frames and furniture for umbrellas, sunshades, parasols, and other such like articles.

Dated May 18, 1868.

1620 J. W. Anderson, Glasgow. Improvements in temples for looms, and in the cases containing them.

1627 A. M. Clark, Chancery-lane. Improvements in apparatus for ironing and finishing linen and other fabrics. (A communication.)

Dated May 20, 1868.

1646 A. G. Hutchinson, Stoneycroft, Liverpool, builder. Improvements in apparatus for offering resistance to the opening of doors, windows, and other movable parts, and for giving alarms in cases of improper or burglarious attempts to open the same.

Dated May 21, 1868.

1685 A. M. Clark, Chancery-lane. Improvements in differential gearing applicable to lifting jacks, cranes, windlasses, and other purposes. (A communication.)

Dated May 22, 1868.

1692 J. Oury, Blois, France, civil engineer. An improved construction of meter or apparatus for measuring liquids or gases, applicable also for obtaining motive power.

Dated May 23, 1868.

1702 J. S. Richard, La Mairie du Temple, Paris. Improved arrangements of apparatus for stopping the motions of spinning machinery, and machinery for manufacturing textile fabrics when a thread breaks or a bobbin is exhausted, or the tension of a thread is too great.

Dated May 25, 1868.

1706 H. W. Everard, Manchester. Certain improvements in articles of wearing apparel called braces.

1710 F. Hargreaves and J. R. Collins, Bradford, Yorkshire, stuff manufacturers. Improvements in looms for weaving.

1712 A. M. Clark, Chancery-lane. Improvements in rotary engines or apparatus, applicable also as a pump blower or liquid meter. (A communication.)

1714 H. Ferguson, South Wharf-road, Paddington, and A. Mulvey, Kilburn, Middlesex. Improvements in machinery for cutting tenons and shoulders.

1716 W. W., R., and M. W. Johnson, Limehouse, Middlesex, lead manufacturers and merchants. Improvements in the manufacture of sheets of lead or tin, or alloys or compounds of these metals.

1718 J. E. Holmes, Ruabon, North Wales. Improved machinery for cutting or dressing stone.

Dated May 26, 1868.

1722 J. Ferrabee, Briscombe Port Mills, near Stroud, Gloucestershire, engineer. Improved machinery for feeding carding engines.

1723 H. J. Bakewell, Devonport, Devonshire, engineer. Improvements in apparatus for steering ships.

1725 C. E. Brooman, Fleet-street, City, patent agent. Improvements in decolourizing tannin juices. (A communication.)

1727 A. and C. Edmeston, Salford, Lancashire, engineers and machinists. Improvements in machinery or apparatus for printing hanks of yarns or threads and warps with one or more colours.

1728 A. S. Macrae, Liverpool, produce broker. An improved process and composition for removing ink and colours from paper, and dirt from rags and other paper stock. (A communication.)

1731 T. Smedley, Holywell, Flintshire, hotel keeper. Improvements in brakes for carriages on common roads.

1732 W. E. Newton, Chancery-lane. Improvements in rotary, steam, and other engines. (A communication.)

1733 W. Buttery, Sheffield, manager at powder flask manufactory. Improvements in apparatus for turning and closing cartridges.

1734 I. B. Miller, Hackney-road, Middlesex. Improvements in the manufacture of packing for steam engines and other machinery. (Partly a communication.)

1735 W. E. Debenham, Massingham House, Haverstock Hill, Middlesex. Improvements in wristbands, cuffs, collars, and other such like articles of wear.

1736 B. Burton, Brooklyn, New York, U.S. Improvements in breech-loading firearms and cartridges.

1737 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in ploughs and other implements for cultivating land. (A communication.)

1738 W. B. Lord, Stamford Lodge, Hampstead Heath, Middlesex. Improvements in portable filters.

1740 A. M. Clark, Chancery-lane. Improvements in apparatus for dressing millstones. (A communication.)

1741 F. Wirth, Frankfort-on-the-Maine, Germany. An improved regulator or governor for steam and other engines. (A communication.)

Dated May 27, 1868.

1742 J. Dixon, Hillsbro' Hall, Sheffield. An improved coupling link for railway vehicles and other purposes. (A communication.)

1743 H. A. Bonneville, Sackville-street, Piccadilly. Certain improvements in the permanent way of railways. (A communication.)

1744 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in breech-loading firearms. (A communication.)

1745 W. Cooper, Bradford, Yorkshire, iron and tin plate worker. An improvement in sliver cans or cotton cans.

1746 J. Morris, Liverpool, printer. An improved method of, and apparatus for, facilitating the finishing of printed sheets of paper.

1747 J. Vidie, Dean-street, Finsbury-square, City. An improved process for the ornamentation of glass, earthenware, and other similar materials.

1748 H. and G. Kearsley, Ripon, Yorkshire, agricultural engineers. Improvements in mowing and reaping machines.

1749 H. E. Mines, Cheltenham, Gloucestershire. Improvements applicable to register stoves or grates for curing smoky chimneys and controlling the draught of air.

1750 M. Gray, Highbury, Middlesex, engineer. Improvements in the manufacture of insulated electric conductors.

1751 J. Scholl, Berwick-street, Soho, engineer. Improvements in gas burners, and in apparatus to be used in connection therewith.

Dated May 28, 1868.

1754 R. Fell, Robinson-row, Middlesex, engineer, and R. Barlow, Shacklewell-lane, Middlesex, builder. Improvements in apparatus for preventing waste of water in or from water-closets and drinking fountains, cisterns, tanks, and other like receptacles.

1756 W. Alexander, Liverpool, ship owner. Improvements in the arrangement of mechanism for applying auxiliary power to sailing ships.

1758 F. Hauducœur, Rue St. Maur, Paris, merchant. An improved apparatus for malaxating butter.

1760 W. E. Newton, Chancery-lane. Improved apparatus for hopping beer. (A communication.)

1762 J. and J. B. Palmer, Palace Works, Old Ford-road, Bow, Middlesex. Improvements in the manufacture of matches and fusees, and of friction surfaces to be used therewith. (Partly a communication.)

1764 R. H. Bentham, Bedford-row, Middlesex, architect. Improved apparatus for facilitating the flow of liquids from barrels or other closed vessels, and for lifting or forcing liquids to any desired height.

1766 T. S. Horn, Grove-street, Newcastle-upon-Tyne, agent. Improvements in miners' safety lamps.

Dated May 29, 1868.

1770 J. Turnbull, Edinburgh, Writer to the Signet. Improvements in connecting and disconnecting carriages and waggons on railways, and in the apparatus connected therewith.

1774 E. Newton, Mount, Sheffield, merchant. Improvements in the means of, and apparatus for, obtaining and applying motive power.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated June 5, 1868.

1845 H. A. Bonneville, Sackville-street, Piccadilly. A new and improved process for feeding sugar factories or distilleries. (A communication.)

1853 E. A. Dana, Brookline, Norfolk, Massachusetts, U.S. Improvements in the construction of projectiles for rifled cannon or ordnance.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," June 16, 1868.

362 J. Combe and J. Barbour. Machinery for hackling and scutching flax.

368 H. B. Wright. Apparatus for sweeping chimneys.

372 R. A. Jones. Warming and ventilating vessel.

383 P. Graham. Stoppers for closing bottles.

390 B. J. Jones. Machinery for manufacturing clog soles.

391 F. Ardache. Apparatus for winding flat cords.

392 M. P. W. Boulton. Apparatus applicable to propulsion and aerial locomotion.

396 H. Moore and J. Hamilton. Construction of furniture expanders.

401 A. E. Borgen. Preparation of phosphor free matches.

402 W. J. M. Rankine and J. M. Gale. Condensing steam.

411 W. Tongue. Machinery for preparing fibrous materials for combing or spinning.

418 A. B. Ibbotson. Steel spring railway fastenings. (A communication.)

419 W. Hann. Safety lamps.

421 W. Drake. Machinery employed in the cutting of wood laths.

433 J. Key and E. Hoskins. Metallic bedsteads.

434 H. Woodward. Knife cleaner.

439 W. B. Marston. Lamps for lighting railway carriages.

440 N. C. Szerelmey. Rendering paper fabrics waterproof.

441 N. C. Szerelmey. Preserving wood.

445 W. Burgoyne. Better and invoice holders.

452 H. Schlotter. Apparatus for raising water.

458 J. W. Melling. Machinery for excavating coal.

459 C. and L. Verhulst. Construction of fireplaces. (A communication.)

463 G. Seamer. Manufacture of silk fancy weavings.

470 S. C. Lister. Looms for weaving cut pile fabrics.

479 W. Wootton. Envelopes.

480 H. B. Condy. Manufacture of acetic acid.

488 J. Wood. Apparatus for indicating the position of railway points.

490 F. Tolhausen. Machinery for brush making. (A communication.)

492 G. Roberts. Candles.

500 J. P. Lack. Albums and scrap books. (A communication.)

505 J. S. Raworth. Mode of connecting and disconnecting revolving cylindrical surfaces.

509 W. Easterbrook. Machinery for actuating and controlling railway points and signals.

532 J. and J. Hinks. Portable stoves.

537 J. and J. Thompson. Fastening railway rails.

561 M. Henry. Manufacture of nails. (A communication.)

572 G. Davies. Taps. (A communication.)

582 M. A. F. Mennons. Bristle brushes. (A communication.)

612 R. Nicholls. Combined material or fabric to be applied to the manufacture of bags.

632 J. L. Jacquet. Heels for boots and shoes. (A communication.)

664 W. E. Newton. Construction of boats. (A communication.)

743 A. M. Clark. Paving roads. (A communication.)

770 A. M. Clark. Steam pumps. (A communication.)

829 J. Wallis. Apparatus for dressing millstones.

844 J. Browne. Auxiliary propulsion.

1025 A. P. Price. Treatment of ores.

1090 M. Hawthornthwaite and T. Abbott. Taps, cocks, or valves for water, gas, or other liquids.

1162 A. V. Newton. Anchors. (A communication.)

1205 C. Martin, W. Barrett, and T. S. Webb. Treatment of titaniferous iron ores for the manufacture of iron.

1309 H. Howse. Safety matches.

1365 A. Clark. Steam generators and furnaces. (A communication.)

1522 S. Moulton. Treatment of vulcanized india-rubber for obtaining a substance of a mossy nature.

1535 A. M. Dix. Apparatus for supplying fixings to casks.

1578 J. Dewar. Preserving certain vegetable substances.

1628 J. Mitchell. Railway and other carriage springs.

1682 C. Barnard. Chairs.

1719 H. L. A. Lippens. Looms for weaving.

1736 B. Burton. Breech-loading firearms.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed June 12, 1868.

3548 L. A Damm	3590 W. A. Gilbee
3554 H. Atkinson	3604 H. H. Murdoch
3558 W. and F. Bates	3614 W. H. Richardson
3559 J. Hargreaves	3627 J. Kenyon

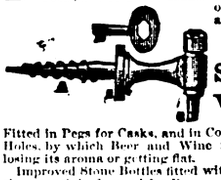
NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department), on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennett Woodcroft, Great Seal Patent Office, 25, Southampton-buildings, Chancery-lane.

THE BURTON TAP.

ATLEE'S PATENT.

BEST and CHEAPEST, Screws into Tap Cock, avoids use of mallet and paper, without trouble, waste, or shaking the Beer. Prices low, and every variety kept.



BOURNE'S PATENT

SELF-ACTING VENT VALVE,

Fitted in Pegs for Casks, and in Corks and Bungs for Jars, with Tap Holes, by which Beer and Wine may be kept on draught, without losing its aroma or getting flat.

Improved Stone Bottles fitted with Taps and Valves, in all the usual sizes, much in demand for Beer and Wine.

Wooden Taps for Jars, &c., at specially low prices.

WHEELER AND CROUCHER,

4, CULLUM-STREET, LONDON, E.C. B 79

INDIA-RUBBER, GUTTA-PERCHA, and TELEGRAPH WORKS COMPANY, LIMITED, Manufacturers of

VULCANISED INDIA-RUBBER.

Buffer Springs for Locomotives and Railway Trucks, Valves, Sheet, **Washers**, Suction and Delivery Hose, Tubing for Gas, &c., **Machine** Belting, Elastic Steam Packing in Rope, Sheet, and **Rings**, &c., &c.

EBONITE.

Sheet, Pumps, Taps, Tubing, &c., for acids and vinegar; Photographic and Surgical Articles, Speaking Tubing, &c.

GUTTA-PERCHA.

Sheet, Tubing, Pump Buckets, Valves, Machine Belting, Vessels for chemicals and acids, &c.

WATERPROOF.

Clothing, Hot-Water Cushions, Matting, Ground Sheets, Aprons, Waggon Covers, &c., &c.

TELEGRAPH INSTRUMENTS.

Insulators, Batteries, Insulated Wire, and every description of Telegraph Apparatus and Stores.

Vulcanised India-rubber specially prepared to withstand the action of tropical climates.

WORKS, SILVERTOWN, ESSEX. B 41

PHILLIPS'S PATENT SOLID FLANGE GIRDERS give double the strength of ordinary riveted plate girders of corresponding sectional area and weight, and are supplied in the usual sections at a lower rate per ton.

Particulars furnished on application to the patentees, W. and T. Phillips, 25, Coal Exchange, E.C.

PHILLIPS'S PATENT IMPROVED FIRE-PROOF FLOORING dispenses with the use of all Wooden Fillets and Laths; can be laid by any labourer, and the ceiling plastered immediately; is light and indestructible, and in combination with the Iron Joists, forms a perfect structure at a trifling cost over the ordinary combustible Timber Floors.

W. and T. Phillips, Patentees, 25, Coal Exchange, E.C.

PHILLIPS'S ROLLED WROUGHT-IRON JOISTS AND BEAMS are specially manufactured from a tough and elastic Metal, and are supplied at the cost of the inferior descriptions of iron in the market.

W. and T. Phillips, 25, Coal Exchange, E.C. A 36

CARR'S PATENT DISINTEGRATOR.—This unique and efficient Mill, unparalleled for novelty, wholesale execution, and despatch, is rapidly superseding all other pulverizing machines at the undermentioned works, at an immense improvement to their manufacture, and saving in steam power and labour.

FIREBRICK, SANITARY TUBE, AND ENCAUSTIC TILE WORKS AND POTTERIES.

In the above Works it is used for reducing to a fine granular powder Fire Clays, Marl, Ganister, Burnt Bricks, &c. The strong and powerful 6ft. 3in. size is alone competent to satisfactorily cope with such hard materials as these, which size is also used for Chrome Ore, &c. The amount that can be passed through one of these large ones varies with the power of the engine used to drive it, up to as much as 30 and even 40 tons an hour. This capacity is two and a-half times greater than that of the 4ft. ones, and their weight is 57cwt., instead of 27 only.

PATENT FUEL MAKING.

The 4ft. size is the one used for this purpose, which will reduce from 70 to 100 tons in ten hours of either slack coal or mineral pitch to a fine granular powder, exceedingly like that of gunpowder.

ARTIFICIAL MANURE WORKS.

These Machines have been long considered indispensable adjuncts to this business, nearly all of the Works for same being already supplied with one or more of them.

A pamphlet, fully describing the Disintegrator, with woodcuts, prices, and a long list of its purchasers, will be forwarded free on application to the Patentee, as below.

THOMAS CARR (Patentee).
Montpelier, Bristol. B 63

COCKER BROTHERS
(Successors to Samuel Cocker and Son),
SHEFFIELD.
ESTABLISHED 1752.

MANUFACTURERS OF STEEL FILES AND WIRE; Also of "COCKER'S" PATENT STEEL ROPE WIRE

In long lengths, from 10lb. to 40lb. pieces, without welding, and capable of bearing as high a breaking strain as any in the market. Each piece warranted to twist round its own diameter.

Three First-Class PRIZE MEDALS were awarded to SAMUEL COCKER and SON, Sheffield, at the Great Exhibition of Industry, London, 1851.

First-class PRIZE MEDAL was awarded to COCKER BROTHERS at the Universal Exhibition of Industry, Paris, 1855, and MEDAL of HONOUR awarded to COCKER BROTHERS, by the Society of Arts and Industry, London, 1856. A 26

TO ENGINEERS.

THE "FIELD" TUBES can be fitted to already existing boilers. They will either affect a considerable saving in fuel or enable boilers now short of steam to keep full steam.—For price and particulars apply to Mr. LEWIS OLRICK, Consulting Engineer, 27, Leadenhall-street, London. A 38

THE "FIELD" BOILER is the most economical steam boiler as to space, fuel, and price. It is equally adapted for stationary, portable and marine engines. Illustrations and full particulars may be obtained by applying to Mr. LEWIS OLRICK, Consulting Engineer, 27, Leadenhall-street, London, E.C. A 39

MATHEMATICAL INSTRUMENTS, &c.
64, Charing-cross, S.W.

HOLTZAPFFEL and CO. supply first quality INSTRUMENTS at second quality prices. A visit of inspection is solicited. A 32

THEODOLITES, LEVELS, CIRCUMFERENTERS, MATHEMATICAL DRAWING INSTRUMENTS, SCALES, TAPES, CHAINS, T-SQUARES, RULES, &c.

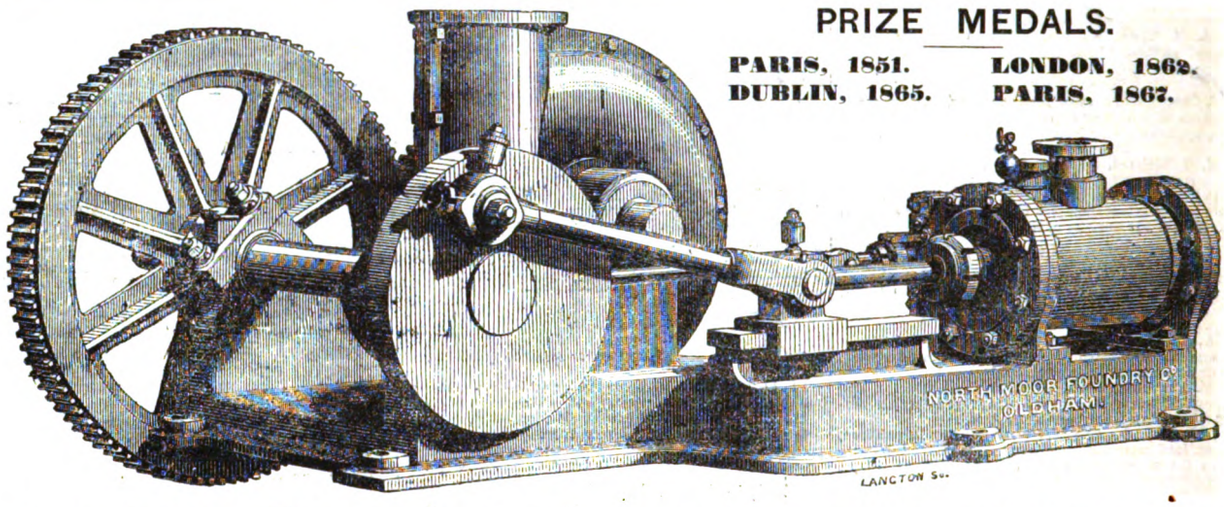
J. and W. E. ARCHBUTT, 201, Westminster-bridge-road, Lambeth, near Astley's Theatre, manufacture the above and every description of Surveying Instruments, unequalled for quality and price. Illustrated Priced Catalogues free on application. Every article warranted. Second-hand instruments of all kinds by the best makers always in stock. A 5

THE LONDON DRAWING ASSOCIATION, for supplying Engineering, Mechanical, Architectural, and General Drawing Designs, Maps, Plans, Tracings, &c., &c.
Duke-street, Adelphi, London. Enclose Stamp for Prospectus.
FREDERICK YOUNG, Manager. A 41

TO OPTICIANS and SHIPS' COMPASS MAKERS.—CAUTION.—Having ascertained that a certain party has been endeavouring to introduce Compasses which directly infringe our patent for the Self-compensating Liquid Compasses, we Hereby Give Notice that Legal Proceedings will at once be taken against all persons dealing in such Compasses without our licence.
J. C. WEST and Co.
Makers to H.M. Navy, 92 and 93, Fleet-street, London. B

PRIZE MEDALS.

PARIS, 1851. LONDON, 1862.
DUBLIN, 1865. PARIS, 1867.



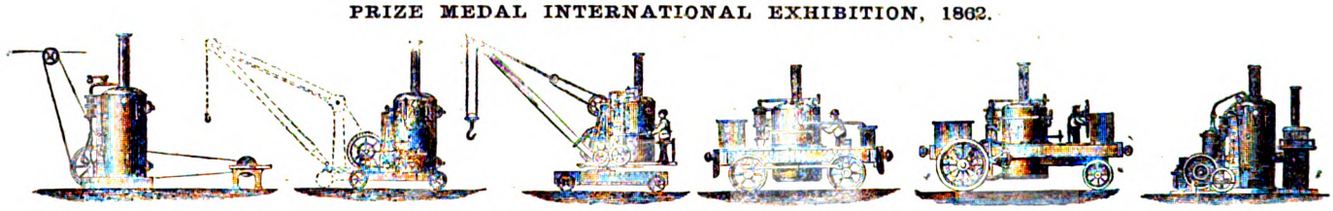
The above shows a Steam Engine and Centrifugal Pump, complete, on one frame, capable of raising 140,000 gallons per hour to a height of 25ft. Price, £150.

Schiele's Turbines, Platt and Schiele's Fans, Schiele's Blast Engines, Schiele's Governors, Schiele's Ship Ventilators, Platt and Schiele's Mine Ventilators, Schiele's Gas Exhausters, Variable Expansion Gear, Centrifugal Pumps, Patent Couplings, Cotton Gins, &c., &c.

THE NORTH MOOR FOUNDRY COMPANY, OLDHAM.
B 43

CHAPLIN'S PATENT PORTABLE STEAM ENGINES AND BOILERS.

PRIZE MEDAL INTERNATIONAL EXHIBITION, 1862.



Stationary Engine. From 1 to 30 Horse Power. No Building required.

Portable Hoist. 1 to 30 Horse Power. With or without Jib.

Steam Crane. 30 Cwt. to 20 Tons. For Wharf or Rail.

Contractor's Locomotive. 6 to 27 Horse Power. For Steep Inclines and Curves.

Traction Engines. 6 to 27 Horse Power. Light and Heavy.

Ship's Engine. Winding, Cooking, & Distilling Passed for Half Water.

FROM the STRENGTH, SIMPLICITY, and COMPACTNESS of these ENGINES they are extensively used for GENERAL PURPOSES, and also in situations where Steam Engines of the ordinary Construction cannot be applied.

ALEXANDER CHAPLIN & CO., PATENTEES AND SOLE MANUFACTURERS,
Cranston-hill Engine Works, GLASGOW.

Engines of each Class KEPT IN STOCK for SALE OR HIRE, and all our Manufactures GUARANTEED as to EFFICIENCY, MATERIAL, and WORKMANSHIP.

Parties are Cautioned against Using or Purchasing Imitations or Infringements of these Patent Manufactures. A 29

Printed by ROBERT SMILES, and Published by him at the Office of ROBERTSON, BROOMAN, and Co., 166, Fleet-street, in the Parish of St. Dunstan-in-the-West, in the City of London.—Friday, June 19, 1868.

LIQUEFACTION OF GASES.

WHATEVER views may be adopted respecting the abstract nature of cohesion, or that mysterious agency which binds together the particles of matter,—whether the atomic theory or that of infinite divisibility be received,—it is nevertheless true, though unaccountable, that heat tends to relax the fetters of natural union, and cold and pressure to rivet them closer. The force with which the results of the application of any of these agents acts is known as expansion and contraction, and their power is irresistible. But a very trifling allowance is needed to allow them to expend their force with impunity, but unless that space be afforded them, the most solid masonry, the heaviest metallic construction, would be shaken by their effect. According to the natural constitution of bodies, and the circumstances under which they are placed with regard to temperature and pressure, so do they exist in one or other of their three limited conditions, namely, solid, liquid, and gaseous or aeriform. Some bodies—water, for example—pass from one of these stages to another when subjected to simply natural variations of temperature, but the majority require artificial means to compel them to change their state. To liquefy bodies, other than gases, is incomparably an easier task than to solidify. By the aid of electricity the most refractory substances can be liquefied, and their molten globules falling upon the table of the laboratory, bear witness to the invincible agent employed in their reduction. It may be said that every solid substance can be rendered liquid, or very nearly so, but the same cannot be stated with respect to the opposite operation of solidification. There are some gases which have hitherto defied all the attempts of the most experienced and skilful chemists to reduce them to a liquid much less to a solid form.

Of the many able experimentalists and *savans* who devoted themselves to the task of accomplishing the liquefaction of gases, none have been more distinguished or successful than Faraday. The basis of his operations was founded upon the circumstances attending the liquefaction of chlorine. This gas is soluble to a considerable extent in water, which, at a temperature of 15½deg. Cent., absorbs nearly twice its own volume. At a few degrees above zero this mixture of chlorine and water freezes, throwing down a yellowish substance containing about a quarter part of chlorine and three quarters of water. It was upon this substance that Faraday experimented. He enclosed it in a strong glass tube sealed hermetically, and then plunged it into hot water. The compound solution was decomposed and liquefied, the water returning to its original condition. But the case was otherwise with the chlorine, which, not having sufficient space to expand and return to the gaseous state, was condensed, by the elastic pressure of its own vapour, into a pale amber-coloured liquid. The pressure necessary to effect its liquefaction, and which must have been excited by its own efforts to expand, was about four atmospheres. By applying this principle of confining solid and liquid substances, capable of furnishing under various changes of temperature large volumes of gas in strong envelopes of glass or metal upon an extended scale, numerous gases were reduced to the liquid state. They were, in fact, all compelled to endeavour to return to their original state in a space too small to allow of the necessary expansion, and the enormous reaction generated a pressure sufficient to liquefy them. That many of these experiments were attended with much danger, and that accidents arose occasionally, is well known, but the man of science is equally brave in his own sphere as the man of war, and life is as frequently risked in the laboratory and workshop as in the field of battle or on the stormy ocean. Until recently, great difficulty was experienced in liquefying the protoxide of nitrogen, represented by the chemical formula NO, and also termed nitrous oxide; it is, however, best known by the name of laughing gas. A pressure of about fifty atmospheres is required for its condensation, and it is now manipulated so safely that it may be poured in the open air from one jar into another without the least fear of explosion. Some remarkable circumstances attend the liquefaction of this gas. A small portion of mercury introduced into it congeals with the rapidity of thought, and assumes all the appearance of bar silver. If at the same time a piece of lighted charcoal be placed in it, a vivid illumination is the result, and we thus witness in close conjunction to one another temperatures of extreme divergence—the one lower than that prevailing in the regions of the north pole, and the other higher than that emitted by the most intense furnace.

Carbonic acid CO^2 is liquefied with facility at a pressure of about twenty-eight atmospheres, yielding a colourless fluid, which requires to be enclosed in vessels of great strength and solidity, as the elastic force of the vapour is of a very powerful nature, and an explosion would be attended with serious results to those near at hand. Besides condensing this gas to a liquid condition, it has also been solidified, converted into a transparent mass resembling ice, and also produced in a form somewhat similar in colour and weight to snow. Under this form the solidified gas can be preserved in the open air for a great length of time, and manipulated without fear of any dangerous consequences. It is by the aid of these substances that temperatures are produced of an intensity of cold scarcely credible, and they are justly termed frigorifics. If carbonic acid in the state described be wetted with ether a temperature of 87deg. Centigrade below zero is produced, and the ordinary temperature of the liquid protoxide of nitrogen is 90deg. below the same point. A degree of cold yet more intense is obtained by subjecting these frigorifics to a quick evaporation in an exhausted receiver, when a temperature of 120deg. below the melting point of ice has been recorded. The contact of these frigorifics with the human flesh sears it like the touch of red-hot iron, and cold pieces of metal plunged into them hiss in the same manner as when hot metal is dipped into water. A jet of cold water thrown upon them re-converts a portion of them into gas, while the water itself congeals with a sharp report. The theory of these actions and reactions is, of course, readily explainable, upon the principle of specific and latent heat. In the last example, the frigorific robs the water of an amount of latent heat sufficient to convert a portion of itself into gas, and at the same time reduce the latter into a frozen mass. The resources at our command for producing elevated temperatures are far superior to those we possess for obtaining low ones. If necessary, we can heat bodies to a temperature of 2000deg. Centigrade; but, until the researches of Faraday, we were not able to produce a temperature lower than 50deg. below zero, and now we are limited to 120deg. below the same point. So that, while we can rise 2000deg. in one direction, we can descend only 120deg. in the other. A very peculiar feature of these frigorifics is that they appear to lose the affinities and qualities which distinguished them in their gaseous or normal state. Thus the most inflammable substances can be brought into intimate union with them without evincing any of those effects that would occur were they combined in their original condition. Sodium, a metal that takes fire spontaneously, exhibits not the slightest appearance of combustion when placed in contact with the liquefied protoxide of nitrogen. Antimony, which inflames rapidly in the presence of free chlorine gas, remains unaltered in substance and appearance when subjected to the influence of that gas in a state of liquefaction. It would almost appear as if the intense state of cold in which those bodies existed rendered inert and powerless those active qualities and affinities which would unquestionably have been displayed under different circumstances.

RECENT GUNNERY EXPERIMENTS AT SHOEBURYNESS.

WE last week noticed the gun practice which was made on the Tuesday and Wednesday previous to our issue, against the Plymouth shield and the 15-inch rolled and hammered plates. This practice was resumed yesterday week, first against the upper portion of the Plymouth shield. The first round was a 12-inch shell, with full charge, aimed at the upper part of an extra plate placed on the front of the shield, and which it broke into several pieces. It penetrated 16in. and exploded backwards, doing no damage at the rear of the shield beyond fracturing another horizontal iron plank. The Rodman gun, with a full charge, was then brought to bear on the upper part of the shield. It struck the curved plate at the left-hand top corner, a portion of which was already knocked off, and broke it in two, doing no further damage. Round No. 3 was a shell from the 12-inch gun, fired with a charge equivalent to 1,000 yards range. The shell struck the second plate from the left hand, carrying away a piece from the corner, and bursting, the explosion lifting up a large triangular fragment of the adjoining plate previously broken, and hurling it on the roof of the building. This mass of iron was about 6ft. base by 5ft. sides, and remained pivoted on one of the large roof bolts, which held it without breaking. Inside the casemate at the rear, the ironwork in connection with the roof was much distorted, and a great cavity, admitting daylight, was formed through the plates, the head and point of the shot remaining jammed amongst the débris of the cavity. The fourth round was a 10-inch shell, with a reduced charge, which hit in a horizontal line with the last one, but some feet to the right, and over the porthole. It penetrated 16in., and burst outside, driving back a corner of the plate struck, and loosening the washers in various portions of the recessed part of the arch over the porthole. In the fifth round the shell struck the granite basement and smashed out some large pieces. The sixth and last round at the Plymouth shield was a 10-inch shell, fired with a powder charge of 48lb. The shell broke away a space of 15in. in the lower proper left side of the front plate above the porthole, the fissure extending from the corner of the plate to the corner of the port and traversing the indent of a previous shot.

The firing was next directed against the granite base on which the target stood. This forms a plinth about 4ft. high, projecting about as much from the surface of the shield, the step being rounded off. The shot—a 450-pounder, from the Rodman gun, with full powder charge—struck the granite towards the right hand, ploughing a furrow some 5ft. wide and 3ft. deep, smashing the granite to powder, and scattering a cloud of fragments and dust around. After this shot two rounds were fired at Sir John Brown's solid rolled 15-inch plate, which our readers will recollect was merely stood against some iron standards and a few balks of timber

Digitized by Google

This target had already had three rounds fired at it with a result highly creditable to the plate, considering the conditions under which it was tested. The first was a 12-inch shell, with 76lb. of powder, and which struck the plate about 2ft. from the end, which it broke off and hurled about 6ft. to the rear. The second shot, which was from the Rodman gun, with full powder charge, struck the plate near the centre of the original length, and close to where it was hit by the two shots of the previous day. The plate at this point was already severely cracked, and the result of the last shot was to complete its destruction, the plate separating into four pieces. The fractures showed a splendid quality of iron, although here and there symptoms of bad welding were visible, and this was all the most adverse criticism could pronounce against it. In its favour there was everything to be said. Considering its unsupported position, and the widely different conditions under which it was fired at to those of a fort where it would be fixed as a defence, it stands out at once as a great success. Although the Plymouth fort stood a good amount of battering, it is to be remembered that it has been improved upon by replacing some of the bars by plates. These were just the points that withstood the firing the best, and this strengthens the conclusion that a mighty strength of resistance would result from the use of a single solid plate instead of a compound laminated plating.

This was the conclusion of the third day's experiments, and at this point we may pause to notice the recorded details of the practice as regards the forces and velocities of the shots fired, and which are as follows:—The Woolwich 12-inch rifled 600-pounder, with 76lb. pellet powder, 5,588 foot-tons, 1,159ft. per second velocity. The 10-inch rifled 400-pounder, with 60lb. l.g.r. powder, 4,431 foot-tons, 1,264ft. velocity. The 15-inch smooth-bore Rodman, with 50lb. English powder, equal to 60lb. American, 4,215 foot-tons, 1,161ft. striking velocity. In the same gun, with 83½lb. charge—equal to 100lb. American powder—the velocity was above 1,400ft., and the total energy about 4,000 foot-tons.

Upon the resumption of the experiments on Tuesday last, a structure known as the "War Office Casemate" was the object of attack. This casemate was manufactured at the Millwall Iron Company's works, and was designed with the view of testing the resistance offered by a given weight of iron plate disposed in various thicknesses and positions. It is divided into six sections, each one of which represents a different system, the whole being lettered from A to F. The first section consists of an 8-inch solid plate placed direct upon the 2-inch skin which is common to all the series. The second is of 4½-inch plate upon a backing 7in. deep, formed of channel-iron placed back to back. The third is a 6-inch plate, with backing 7in. deep of Hughes's hollow stringers. The fourth is a 4-inch plate, with 7-inch backing of channel iron; the fifth is a 4½-inch plate resting partly upon 7-inch backing of channel iron and partly, with only the interstices between itself and the inner 2-inch skin, filled up with 7in. of concrete, forming the sixth section. The structure was roofed in with brick arches and concrete, as in ordinary casemates. The firing was from the 7-inch, 9-inch, and 10-inch rifled guns and the Rodman 15-inch smooth-bore gun, with battering charges, and at the same range as the Plymouth shield, viz., 200yds. Only Palliser shells were used, these having established their superior penetrative power over the Palliser shot.

Twenty rounds were fired in all at this target, the first being a 7-inch shell, which struck the 8-inch plate, penetrating about 8¼in., but doing no damage to the rear. The second round, a 7-inch shell, struck the 4½-inch plate supported by 7-inch channel-iron backing. It penetrated 14in. into the target, but caused no damage to the rear. The third shell struck on the vertical junction of the last plate fired at, with the 6-inch plate backed by hollow stringers. The result was a penetration of 8¾in., the head of the shell remaining in the hole, and the rear remaining undamaged. The above three portions are marked A, B, and C respectively, and they are backed with a massive tapering concrete pier. The fourth shell struck the last-named section (C) where it has behind it 2ft. 6in. of concrete, strengthened by iron girders. The penetration was 10½in., with half a dozen nuts stripped off in the rear. The fifth shell struck that portion of the target covered by 4-inch plates upon 7-inch channel iron. The plate buckled ½in. for about 2ft. around the shothole, and the total penetration was 13½in., the head of the shell remaining in the hole. Seven more nuts in the rear were stripped off the bolts. The sixth shell struck the 4½-inch plate on concrete backing, penetrating 14in. into the structure.

The practice now commenced with 9-inch shells, the first round striking section A of the target, penetrating 13in. The second shell struck the B section, penetrating 21½in., the plate buckling considerably, and seven nuts twisted askew in the rear. The third shell struck on a bolt in section C, causing a buckle of ½in. at the top edge of the plate, the penetration being 18½in. The fourth shell struck the same section, penetrating 14½in., and clearing off five small nuts in the rear. The fifth shell hit on section D, the penetration being 9ft. 8in. At the rear the ⅝-inch iron skin mantlet was driven back 8in., and twenty small nut-heads were stripped off. This portion was driven back by a bolt, and the mantlet skin was turned up also beside the port, the whole forming a considerable smash. The sixth round struck upon the E section, penetrating 22½in., and causing no damage in the rear. The 10-inch gun was then brought into play, the first shell from which struck the A section, buckling the plate, and penetrating 32in. The second round struck the B section, causing a buckle, and penetrating 4ft. 9½in. The shell was supposed to have burst in the concrete backing. One of the vertical channel irons lifted up a few inches through the concrete roof. The ⅝in. skin at the back of the pier opened slightly at the joints. The third shell struck the section C, penetrating 6ft., and passing into the concrete pier. At rear the covering slip at the angle of the pier ripped open over a length of 5ft. 8in., with ten rivets sheared, and a bulge of 5in. in the ⅝-inch skin on the back of the pier.

The next shell struck the C section in another place and completely penetrated the structure, clearing everything before it, the point of the shell being carried 200ft. to the rear. Some pieces of the ⅝-inch skin were thrown 20ft. away. The point struck was a weak one, being near a joint which was not covered by the backing. This points out the necessity of placing the stringers so that the joints of the plates should be supported by them, instead of having them at right angles to the line of the plates, as at present. The fifth round, with the 10-inch shell practice, struck the D section, making a clean penetration. One of the ⅜-inch mantlet plates in the rear was blown 20ft. away, and the timber screen was smashed up. There was an opening in the back of the target 4ft. in height and of considerable width. The angle iron of a vertical girder on the left of the shothole was curved 3in. out of the straight, a 2-inch bolt was broken off, and the concrete was blown out. The sixth and last 10-inch shell also struck upon the D section, and drove the whole side of the target back from its brickwork setting about ½in. It penetrated 4ft. 11in., lodging in the concrete backing, and bulged the cover plate in the rear, stripping some more small nuts, and cracking the roof slightly all round. After this shot the Rodman gun was fired, a round shot striking the junction of the 6-inch plates above the porthole. It caused an indent 7in. deep, and sheared off a bolt-head 6in. from the face of the target. At the rear the angle iron supporting the ⅝-inch skin over the port bent 3in., thirty small screw-nuts were knocked off, and the whole skin, ⅝-inch plate, was knocked out a distance of 9in. One rivet was knocked out from the top of each port jamb. The second round from the Rodman gun struck the A section of the target, making an indent of 4½in., but doing no further injury.

The result so far was, in the first place, to prove the iron to be of splendid quality, the plates being remarkably free from cracks, and the punctures clean and true. In the next place, the 15-inch Rodman gun, with its heavy charge, has practically failed, having been distanced in penetrative quality by the rifled guns of far smaller calibre and charge. In the third place, the results of the trial were favourable to the system of compound backing and Mr. Hughes's stringers as against the plate and bar system of the Plymouth target. It is true that two clean penetrations were made, but then they both occurred at weak points which can readily be strengthened in future by altering the disposition of the stringers. The casemate underwent another day's pounding on Wednesday, and was finally disabled by a 600lb. shot from the 12-inch gun, propelled by a 76lb. powder charge. We, however, leave the details of the concluding trials for next week. We may, in conclusion, add that the velocities of the respective shells from the 7-inch, 9-inch, and 10-inch guns were 1,460ft., 1,340ft., and 1,290ft. per second, and the bursting charges were 2lb. 6oz., 5lb. 10oz., and 9lb. 10oz.

INDO-EUROPEAN TELEGRAPH.

WE understand that five cargoes of stores, consisting of Siemens' iron posts and insulators, and of wire, left England last week for Persia. These stores will be trans-shipped at St. Petersburg into smaller steamers, which will take them through the Neva and the Volga to Astrachan, where they will again be trans-shipped for the ports of Rescht, Lencoran, and Astara, on the north coast of Persia. From these ports they will be conveyed to the interior on mules. It is expected that these stores will arrive at their destination (about 5,000 miles distant) in the month of October, when the erection of the line will at once be proceeded with, a staff of superintending engineers having already left England for that purpose. The three scientific advisers of the company, namely, General von Luders, the Director-General of Russian Telegraphs; Colonel von Chauvin, Director-General of North German Telegraphs; and Mr. W. H. Barlow, C.E., met lately at Berlin, in order to decide upon the mode of construction of this international work, the execution of which has been undertaken by Messrs. Siemens Brothers, and is to be finished before the end of next year. The cable in the Black Sea is to have three insulated conductors, which are to be enclosed by a copper sheath to protect it against oxidation, and against the attacks of marine insects which abound in these regions. The Indian Government having decided to add another conductor to their existing lines between Teheran and Kurrachee, in anticipation of the increased traffic to be expected from this new line, we may look forward to very perfect communication between this country and its eastern possessions, which is so much needed. The Russian and Prussian Governments have formally declared that in case of war the transmission of commercial messages over the new line will not be interrupted.

ARTIFICIAL GRAPHITE.

WITHIN the last few years carbon in various forms has been much used for various purposes, but more especially for filters and galvanic batteries. When M. Bunsen invented his nitric acid carbon battery, he tried to cut his negatives out of graphite, preferring that which is formed in gas retorts from the distillation of coal. But this material is so untractable that he was obliged to give it up, and he devised an artificial substitute for gas carbon by mixing together finely powdered coke and pit coal. Of these powders he made a paste with water, and then moulded the paste into such forms as he required. After having dried the moulded paste, he then soaked it in a strong solution of brown sugar, and again dried it, and then subjected it to an intense heat, at the same time carefully excluding it from the air. This formed a very good substitute for coal graphite for electrical purposes, but still inferior in conducting power.

A much better artificial graphite is formed in the following manner:—Carefully select the coke, taking none but the brilliant granular pieces, and instead of pit coal use charcoal made from hard wood. These being powdered and mixed in equal proportions, and made into a stiff paste with a thick syrup of brown sugar and gum arabic, and then moulded into whatever shape is required, and left to dry, are then covered with sand, or otherwise excluded from the air, and heated to a bright red heat till the sugar and gum are thoroughly charred. These will bind the whole together, and will form an artificial graphite scarcely inferior to coal graphite for electrical purposes. At present, an artificial porous carbon is being made for filters and other purposes which is somewhat similar in composition to this latter, but we think it would be improved if it were made to approach more nearly. The process for making this porous carbon is the following:—A mixture of animal and vegetable charcoal is ground to a coarse powder and mixed with sawdust and dried. As soon as the material is dried, and while still warm, 20 per cent. of tar is added. When cold, a certain proportion of mineral pitch is added. The articles are then moulded and put into a sheet-iron box, and covered with sand and charcoal powder. They are then carefully calcined for twenty-four hours. The quality of the carbon depends very much on its proper calcination.

This may make a very fair filtering charcoal, but we think it would be improved by the rejection of the bitumen and tar, and instead of these a syrup of gum and sugar used as a binding material. If a very porous charcoal be required, of course the sawdust should be retained. On calcination, the sawdust is partially consumed, and leaves the mass more porous than it would otherwise be, and this for filtering purposes would be a great advantage, for a porous charcoal will absorb more oxygen than a dense one, for which it has a great affinity; in fact, it is the power of absorbing oxygen which makes charcoal so efficacious as a filtering substance, the carbon giving up its absorbed oxygen to the organic matters in the water, thus oxidizing them and destroying their pernicious properties. For electrical purposes this carbon is much inferior to the second mentioned, and also to M. Bunsen's. We may here say a word on carbon filters, for if the purifying properties of charcoal be not properly understood there is danger of drinking more impure water through them than from any other source.

A carbon filter is effective only so long as it contains some of its absorbed oxygen. After this is exhausted the carbon exerts no further chemical action on the water. Of course, it will still act as a mechanical strainer, but it is not the mechanically suspended matters that are so deleterious in water, but the products arising from decomposing organic matter which are in chemical solution. If the water be highly charged with these, the shorter time will the filter be effective. But to make the filter as effective as at first nothing more is required than to drive off the moisture and other foreign matters by calcination. To keep a filter which is in constant use in a thoroughly efficient state the carbon should be recalcined at least once in ten days, but the frequency required can be easily calculated. Given the amount of organic matter in the water passed through the filter daily, the amount of oxygen required to oxidize it can be easily calculated, and the ratio that bears to the amount of oxygen which the carbon will absorb will give the number of days that the filter will remain effective. At present many people think filters are effective as long as they remain unbroken and water will pass through them, a notion which is beneficial to the makers only.

ARTIFICIAL LIGHT IN PHOTOGRAPHY.—No. II.

THE lime light is also very useful in photography. It is, in some respects, worse than the magnesium light, because, notwithstanding its great brilliancy, it does not contain such a large proportion of actinic rays as might be expected. Likewise, it is not ready for use in an instant, like a magnesium lamp, because great bags or gasometers have to be filled with gas, and several gallons of oxygen have to be made before operations can begin. On the other hand, the oxyhydrogen flame is very steady, and gives off no smoke, in which respects it is much better than magnesium. Those employed in enlarging photographs by artificial light, as a business, seem to so equally use the lime and magnesium lights that it is difficult to say which of the two is preferred by practical men. With the lime light a longer exposure is necessary, but, on the other hand, the flame is easily controlled, and gives off no smoke or noxious gases. There are more actinic rays in the lime light than commonly supposed by photographers, the value of the light in this respect having been much understated by many writers, as we know by experiment.

Those who intend to use the lime light extensively in photography had better provide themselves with large zinc gasometers, fitted up with safety valves, such as have recently been described in these columns. Gas bags are not only expensive, but they last a very short time, whilst gasometers made at about the same cost should last a lifetime, with very little trouble in the matter of repairs. Where the operator is likely to do much in the way of moving or travelling, gasometers are, of course, inconvenient, and gas bags may be preferable because of their portability.

When constantly using the lime light, the great danger to be guarded against occurs in the manufacture of oxygen, because if the black oxide of manganese be purposely adulterated or accidentally mixed with organic matter—such, for instance, as soot—an explosion will result after it has been mixed with chlorate of potash, and heated in the retort. Explosions of this kind are of a most deadly character, and in those rare instances when they have occurred, have sometimes killed the operators. When a new sample of black oxide of manganese is bought, a little of it should be mixed with half its bulk of chlorate of potash, and put in a test tube, which should then be heated over the flame of a spirit lamp. If organic matter be present in the black oxide, the whole of the mixture in the tube will go off something like a squib, directly the bottom of the tube gets hot. Having once obtained a good sample of black oxide of manganese, the best plan is never to use any other, because this substance is, strange to say, not altered in the manufacture of oxygen, but remains in the retort when the operations are over. When the retort is cold it should be washed out with water, and the black muddy liquid poured into a large deep dish. The supernatant liquid may afterwards be poured off, and the black oxide which sank to the bottom of the dish may be allowed to dry for future use. Any impure sample of black oxide of manganese may be heated to redness in a covered crucible, which operation will destroy the organic matter, and render the oxide perfectly safe to use in the manufacture of oxygen. In making this gas too much heat should not be applied at first, and the delivery tube of the retort should not be less than half an inch in internal diameter, because sometimes the gas comes off with uncontrollable violence, and would blow off the head of the retort without the above precautions. For the same reason a retort of thin metal is best, because on removing the flame when the gas comes off too violently, the reduction of heat at once makes its beneficial effects visible. For the same reason a retort with a broad bottom is better than one of a globular or tall cylindrical form, because in the former case a thin layer of mixture only is ignited, instead of a great substantial mass, likely to retain a great deal of heat. These remarks, if carefully attended to, will enable anybody to keep the operations of manufacture of oxygen gas under easy and safe control.

An exceedingly brilliant light, very rich in photographic rays, may be made by burning a mixture of nitric oxide gas and bisulphide of carbon vapour. This is a light which might well be utilized in photography were it not that it gives off suffocating fumes of sulphurous and sulphuric acids. Hence this light can only be burnt under a chimney, and no private individual has a moral right to turn such deleterious substances into the atmosphere, to the injury of his neighbours. Supposing apparatus were made to consume these unpleasant products of combustion, the only difficulty to be overcome would be the devising of a jet to give a good flame, because the two vapours must be mixed in certain definite proportions to give the best results. Wrong proportions considerably diminish the intensity of this peculiar light. One way in which we have obtained the light was by passing nitric oxide through warm liquid bisulphide of carbon, and then igniting the product at a jet at the top of the bottle. The flame obtained was very long and pale. The best results can only be obtained with a larger proportion of bisulphide of carbon vapour, such as would be produced by boiling the liquid. The mixture of the two vapours is explosive, so they should not be mixed in large quantities.

The light of common gas or of a paraffin flame is very poor indeed in photographic rays, so as to be useless in portraiture and in enlarging processes. Yet these lights are very useful in printing transparencies on wet or dry collodion, by superposition. Supposing a sensitive plate prepared by any of the dry processes to have a negative placed in contact with its surface, a picture may then be printed by exposing the plate through the negative, at a distance of 18in. or a little more, from a gas flame. The picture will then have to be developed in the usual way, and toned with chloride of gold, or some other substance, to give a pleasing appearance to the eye. Beautiful stereoscopic transparencies upon glass, such as are sold by some of the best philosophical instrument makers, may be taken in this way, and at a future time we may possibly publish detailed instructions how to take such pictures.

THE AERONAUTICAL EXHIBITION.

OUR readers are aware, from our occasional notices, that an extensive exhibition of aeronautical machines has for some time past been in course of preparation. This exhibition opened yesterday, at the Crystal Palace, and will continue on view until the end of next week. We shall, therefore, reserve our

Digitized by Google

notice of the exhibits for our next number, contenting ourselves for the present with a few remarks upon the exhibition generally. Whatever doubt may have been felt as to the possibility of forming anything like an attractive aeronautical exhibition in London is certainly more than dissipated by the present show. In this respect, to commence with, it is a decided success, and might have been still greater had the Aeronautical Society possessed means which would have enabled them to give their proceedings greater publicity, and to make their intentions more widely known. But the exhibition bears evidence of a large amount of careful earnest thinking and working upon a very special subject. It is to be hoped that out of the mass of ideas now placed before the world, a digest will be formed by the united action of the inventors, which shall embody the correct theory of aerial locomotion, and tend to a solution of the question. There is a general expectation that the exhibition will be repeated next year, upon a much grander scale than the present; this idea is warranted by the great encouragement the society has received in its first attempt. Such being the case, we cannot be considered premature if we call the attention of those who wish either to become guarantors, or to offer prizes, to the fact.

That the exhibits are not mechanically perfect in all their details is a circumstance at once evident and easily accounted for. The study of aeronautics has been chiefly pursued by those who are indifferently versed in mechanical laws. It has hitherto been a study more or less of an imaginative character, and has exercised higher flights of thought, in which mechanical motions and arrangements have taken but a secondary part. They have been too earthly and unethereal for the flights of fancies, which would float in space. But the tendency of the aeronautical movement of the present day is to reduce vague and uncertain theories to sober practice, and attention is therefore directed at the outset to mechanical conditions. Hence, one result of this exhibition will be to lead to practical effect being given to the ideas of those whose theories may be sound and feasible, but which yet may be very indifferently illustrated in a mechanical point of view. A careful examination of the exhibition doubtless discloses instances of misapplied talent, but, on the other hand, it also exemplifies progress and the gradual development of the great idea of aerial navigation. We confess ourselves to be less sanguine of ultimate success than many who have toiled at the question for years. There are so many delicate conditions, requiring such extreme care and accuracy in their fulfilment, upon which safety and success depends, that we are justified in accepting with extreme caution anything like an assurance that the accomplishment of the fact is at hand. But then the subject is in its infancy, as regards its practical bearing upon the question of aerial flight, and the Aeronautical Society could have taken no better step for its advancement and development than the one they have—the promotion of an aeronautical exhibition.

ELECTRICITY AND TELEGRAPHY.

IF two zinc plates of equal dimensions, connected with a galvanometer, be plunged at the same moment and to the same depth in a liquid, no result will be shown on the galvanometer. But, according to M. Caudray, if one be first immersed and then the other, a strong current is perceived flowing from one plate to the other, showing that the first is negative. The polarity of the plates depends upon the order of immersion, the second being negative, so that any one plate may be made at will positive or negative according as it is immersed first or second. The polarity may also be reversed when both plates are immersed by touching one or other with a piece of carbon. The strongest effect is noticed when one plate is wholly and the other only half immersed.

Some experiments have been tried lately by M. Edlund on the peculiar effects of elongation in conducting wires due to the passage of a current. From a series of careful experiments he deduces the fact that an electric current traversing a solid body produces an elongation due to itself, and independent of that due to the increase of temperature, this elongation increasing rapidly with the intensity of the current.

We learn from a report recently published that a Russian telegraphic agency exists at Pekin, through which messages are transmitted from the Atlantic to the Pacific Ocean. If the American Government carry out their intended plan of extension through the Russian territory, lately ceded to them, we may probably see, by means of the extension in Russian Asia to the Behring Straits, an almost uninterrupted line of telegraphs round the globe. It is also mentioned in the report, which is full of statistics, that the total amount of telegraph in the world, exclusive of submarine lines, is over 75,000 miles, of which over 52,000 are European.

Mr. W. T. Henley has just sent away from his works at North Woolwich a length of forty-two miles of cable manufactured by him for the Norwegian Government. The core of insulated wire was covered at the Telegraph Construction and Maintenance Company's Gutta-Percha Works, at Wharf-road, and was composed of a seven-strand copper conductor, weighing 107lb. to the nautical mile, coated with three alternate coats of gutta-percha and Chatterton's compound to the weight of 166lb.—making a total weight of core of 273lb. per nautical mile. The core was served with yarn, and sheathed by Mr. Henley with ten No. 6 iron wires, and finally protected with a serving of yarn and Clark's bituminous asphalte compound. The insulation of the completed cable is very high, and, we believe, superior to any that the Maintenance Company have produced from their works. The iron wires were drawn and galvanized by Mr. Henley himself, who has been engaged for some time past most extensively in this branch of telegraphy, who, although possessing large means for not only drawing but galvanizing wire, is now engaged in making extensive additions, in order to be able to produce at any time a larger supply of wire than formerly.

The Telegraph Construction and Maintenance Company have laid a cable across the Straits of Messina to complete a portion of their contract with the Anglo-Mediterranean Telegraph Company. This cable completes the special communication erected by them between Susa and Modica.

The main cable from Malta to Alexandria has just been commenced at the sheathing works at Greenwich, the gutta-percha core having been commenced some time back at their works at Wharf-road.

The "Electric Telegraphs" Bill, after several postponements, was brought before the House last week, and, being read a second time, was referred to a select committee, on the understanding that an instruction will be moved to the committee to inquire into all the important points of the general question. Great delay has been experienced in the promised returns relative to the railway telegraph. Up to the present time particulars have not been received from the North-Western, Caledonian, South-Western, Great Western, and Great Northern. The petitions presented in favour of the bill are very strong evidence of the opinion of the country generally. There has hardly been a chamber of commerce or a newspaper that has not petitioned in support of the Government acquiring the telegraph. The difficulty at present experienced is one of purchase money, the companies requiring twenty-five years' purchase, and the Government offering the highest price of their various companies' shares at a certain date. The one is too high and the other too low, but it is a fair question for arbitration, and one we hope to see an early and satisfactory solution of.

It has been decided that the core of the new cable for the Persian Gulf shall be made of india-rubber of the manufacture known as "Hooper's core." The trial that the India Government gave to this core has proved so highly satisfactory that they are again going to make use of it. The high temperature of the water where this cable will be submerged renders india-rubber more suitable than gutta-percha, on account of its being affected less by temperature.

M. Alvergniat, of Paris, has constructed a new apparatus for proving that electricity does not pass through a perfect vacuum. In a tube, having two platinum wires so placed that their extremities are only $\frac{1}{8}$in. apart, he produces a vacuum by means of a mercurial column. When a vacuum is established, no trace of a spark can be perceived.

In some experiments, tried by M. Felix Lucas, he establishes the fact that the electric spark is visible at a greater distance than a permanent electric luminous ray, whose apparent intensity is 25,000 times that of the spark. The light that is employed in some of the French lighthouses has, we are told, an illuminating power equal to 125 times that of the Carcel lamp. From experiments tried, a spark having a power 200 times less than that of the lamp, is visible at a greater distance than the rays from the lighthouse. It is suggested that by the use of a series of intermittent sparks, a system of lighthouse illumination can be easily made of very great power.

Some highly interesting experiments have been successfully tried lately by M. F. Carré with regard to varying the colour of the electric light. The colour of the voltaic arc has been modified by introducing in the carbons saline solutions of substances having the property of colouring flame. The salts of strontium give a purple light, the salts of copper a green. Nearly the same results are obtained by the introduction of the metallic oxides of these salts. It is stated that the metallic powders do not in any way diminish the conductibility of the carbons. The application of boracic acid to the carbons has the property of considerably increasing the time of their duration. It surrounds them with a protecting varnish which prevents their combustion, acting almost the same as in a vacuum.

The U.S. steamer "Gettysburg" has returned, after an interesting cruise in the West Indies. She has been entirely engaged in making soundings between the British West Indies and the shores of South America. The result has been successful, and establishes the fact that the bottom is muddy, and the depth suitable for a cable. The deepest water was met with between Jamaica and Cuba, as much as 3,000 fathoms having been found.

NEW DOUBLE-ACTION SWITCH.

THE magnificent array of signals and signal boxes that grace, professionally speaking, the entrance to the Charing-cross and Cannon-street Stations, are not only of too elaborate a nature to be employed in smaller instances, but their application would not be attended with an advantage commensurate with the outlay incurred. For ordinary stations not terminal ones, a simpler and less expensive method of working switches is required, and numerous have been the patents and inventions that have been applied to the purpose. A patent has been recently taken out in Belgium for a new switch lever, which renders the operation exceedingly simple, and prevents the carriages getting off the rails through the careless or inattention of the switchman. The system has been adopted by the Belgian railway authorities, and will be readily understood by aid of the annexed diagrams, one of which represents a section and the other the plan of the arrangement. Many of the details are necessarily common to other systems. The box B is of cast iron, and bolted down

FIG. 1

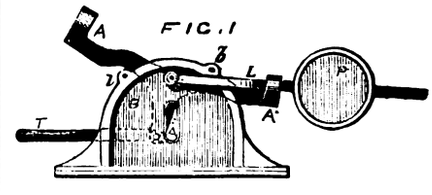

FIG. 2

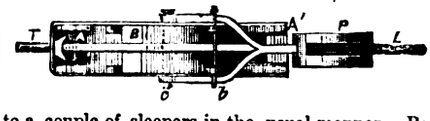

to a couple of sleepers in the usual manner. Between the two vertical sides of this box is mounted upon a central pivot C the lever with three branches A A^1 A^2. Upon the last, A^2, is fixed the switch rod T, the other end of which is connected with the points. The lever handle L carrying the counterweight P is also mounted upon the same pivot bolt c. To shift the points, all that is

Digitized by Google

necessary to do is to reverse the lever either at the extremity A or A^1, which, oscillating upon its centre under the weight of the counterpoise, pulls or pushes the rod T by the medium of the branch A^2. The lever can be maintained in either of the extreme positions by simply passing a small iron pin through one of the eyeholes *b*, cast on the box.

Accidents have frequently happened to carriages owing to the points shifting while the train was passing over them, and, in self-acting points, it is easy to witness the points oscillating backwards and forwards, accordingly as the wheels alternately press them down and release them. It was to obviate this dangerous tendency in common points and switches that Messrs. Livesay and Edwards introduced their patent bar system, as it may be termed, which consists in attaching to the points a long bar by the side of the rail in the vicinity of the points. This bar is kept down by the pressure of the train, and it is impossible for the points to shift during its transit. The bar is of sufficient length to be always pressed upon by a couple of wheels at a time, which is more than enough for the purpose.

THE HANDEL TRIENNIAL FESTIVAL.

DURING last week the Crystal Palace was the scene of one of the greatest—if not the greatest—of musical successes ever achieved. It will be remembered as such by many thousands until the next festival comes to eclipse the last. Its perfect success is due, on the one hand, to the highly efficient arrangements made by Mr. Grove, the secretary; Mr. Bowley, the general manager, and the other members of the executive of the Palace, for the good of the public. On the other hand, we have the labours of Mr. Harrison, the president; Mr. Brewer, the hon. secretary of the Sacred Harmonic Society, and others, by whose exertions nearly 5,000 vocalists and instrumentalists were gathered together in the Handel orchestra from all parts of Great Britain. Above all, and the crowning point of the whole, was Mr. Costa and his admirable direction, without whom and which it is certain the success would have been very incomplete. The attendance throughout was larger than on any previous occasion, not even excepting the great commemoration festival of 1859. The numbers attending the several festivals since their inauguration are as follow:—In 1857 the total was 38,414; in 1859, the commemoration year, 81,319; in 1862 the total was 67,567; in 1865 it was 59,434, and the attendance at the festival just closed was 82,465. With such resources as the Crystal Palace possesses, and with such an executive to turn them to good account, we believe that the latter number will be exceeded at the next triennial festival.

WELSH STEAM COAL.

MOST of our readers are aware that for several years previous to 1866 the steam coal of South Wales, known as smokeless coal, was almost exclusively used on board the vessels and steamers of the Royal Navy, and it gave general satisfaction as regards the speed attained and the evaporative power. In consequence, however, of the recommendation of a committee appointed in 1866, at the instance of some of the north of England members, who complained that undue preference was shown to South Wales coal, it was determined that navy contracts for the future should be in the proportion of two-thirds Welsh and one-third north country coals, the mixture, it was alleged, giving superior results to either coal alone. This arrangement was observed for about two years, but it was soon discovered that the mixed coal did not do the service of Welsh used alone. Repeated complaints followed from the navy officers of the inefficiency of the fuel, and the result has been that the old arrangement is again reverted to, and Welsh smokeless coal is exclusively used. This decision on the part of the Admiralty authorities will add considerably to the demand for South Wales coal, and indirectly it will be a material benefit to the trade, in consequence of the reputation for quality that will thus be given to the coal. We understand that the navy of the Federal States of Germany will in future use Welsh coal.

CONVERSION OF WOODEN SHIPS.

THE latest plan for utilizing our wooden ships of war for defensive purposes is that promulgated by Mr. C. P. Stone, of the 77th Regiment. Instead of placing armour on the sides of the ships, his idea is to cover the deck with a movable iron plating. This method of defence, however, would be entirely ineffective if the sides of the ships were exposed to fire, so Mr. Stone purposes the following expedient. Two or three immense iron tanks are placed in the hold of the vessels, fore and aft, and by gradually filling these with water, the ship is made to sink until the deck is flush with the sea. The tanks are filled by means of valves in the end or sides of the ships, which are opened, and the air in the reservoirs is exhausted by means of a pump, worked by a small engine. When it is necessary to raise the vessel again, condensed air is forced into the tanks, and it rises quickly or slowly, according to the pressure employed. Mr. Stone believes that in this way he can combine the comfort, the commodiousness, and the sailing qualities of the best frigates with the impregnability of a monitor. The deck not being exposed to a vertical or perpendicular fire, it is of course unnecessary that the armour used should be anything like as thick as that of the "Warrior" or "Achilles." A thickness of 3in. is deemed sufficient, and one of the chief features of Mr. Stone's plan is that he proposes that the plating should be removable at pleasure, and only be put on when the ship is going into action. The bulwarks are to consist simply of rails and chains. We admire the simplicity as much as we believe the impracticability of this latest theory of conversion.

ARTIFICIAL GRANITE.

A METHOD of manufacturing artificial granite has just been patented by Mr. P. M. Parsons, of Blackheath, well known by his system of converting cast-iron guns into rifled ordnance. The materials of this artificial granite are disintegrated natural granite mixed with clay, together with pounded glass, lava, or iron slags. The disintegrated granite is obtained by submitting fragments of natural granite to a strong heat, about 700deg. or 800deg. Cent., in an oven, by which, after a sufficient time, it becomes dissolved into a granitic sand, the constituent parts of which, quartz, or feltspar, possess great powers of adhesion. One part of this granitic sand is then mixed with about an equal quantity of pounded glass, or the constituents of glass, or lava, or iron slag, to which is added from twenty to thirty parts of refractory clay, or from thirty to fifty parts of ordinary clay. This mixture is thoroughly kneaded together with a sufficient quantity of water to make it of a pasty consistency. It is then moulded to any form required, and submitted to a degree of heat sufficient to vitrify the mass for about thirty-six hours, which converts it into a hard and durable substance resembling granite. The artificial granite thus produced may be moulded into any forms required to render it suitable for various kinds of buildings, fortifications, docks, and other engineering structures, and particularly for all kinds of pavements, for which its great hardness renders it particularly suitable. When very large blocks are required, it is preferable to make them hollow, and, after they have been baked or burnt, they may be filled with concrete, rubble, &c., to make them solid. Any kind of furnace in which the requisite heat can be generated will answer for dissolving the granite and baking or vitrifying the blocks or bricks; but Mr. Parsons finds Hoffman's annular furnaces perform this operation satisfactorily.

THE SOLID LEVER BRIDGE.

THIS bridge, in its essentially original features, is the invention of Messrs. Cottrell, Liscom, and Merrill. These features may be best explained by describing the mode of construction, as we find it in the "American Railway Times," and which is as follows:—In throwing a span from one abutment to another, the first step of all is to lay down upon each abutment a timber projecting over the edge of the bank a short distance. The length of the portion of the structure projected over the chasm is to that portion upon the bank (which is the balance power), as ten to three. Upon the first layer of timber is placed another, extending further, and firmly treenailed to the first, each successive course projecting further outward over the chasm, and well secured by bolts and treenails, so that when by successive projections the final layer is brought to reach the middle of the span and unite with the corresponding lever from the opposite side, it presents a well proportioned lever, nearly as solid as if sawn entire of one piece, its projecting weight balanced by that portion of the lever resting on the abutments, and the two united and strengthened by two or three additional courses laid over all. The two levers thus making the sides of the bridge are connected by girders, or floor timbers, on which the flooring is laid—the shore ends bound together to form a cradle for the reception of ballast. Thus completed, a span of 200ft. would reach back 30ft. upon each bank, and a span of 500ft. 50ft. back. Over this structure two wooden arcs are placed, of slight and graceful curve, united and securely fastened to the main structure by upright iron rods, and abutting in the shore ends of the bridge.

The advantages of this bridge may be stated thus:—1. Economy and facility of construction. It is claimed that an almost unlimited length of span is attainable, and the building of piers, which in deep and rapid rivers are very costly, and which obstruct the navigation, is avoided, and the cost of scaffolding saved. The plan of construction is such that any carpenters and blacksmiths can furnish the materials and do all the work. 2. Strength—From the peculiarity of the structure, being lightest in the centre, all the material bears its true proportion of strain, and there is no waste, and the distribution of the component parts makes them all act at the greatest mechanical advantage. The sides of the bridge being levers balanced by the shore end, the bridge is relieved of the necessity of sustaining its own weight in the centre where an ordinary truss-work sags the most; and being very light in the centre, there is no unnecessary strain upon the balancing or shore end. 3. The arch adds great compactness and increases the strength of the whole in a peculiar manner. Like any other arch it thrusts laterally against its abutments, but its abutments are the two ends of the bridge into which it is built, and it thus forms with the stringcourses of timber a wooden bow with a wooden string. In order to spread this arch, the chord or upper string timber would have to be dragged apart by longitudinal strain. Thus there can be no deflection of the bridge after it is well set together. It is this combination of the arch on the one hand, with the re-enforced lever on the other, which gives this bridge a strength immeasurably superior to that which the same amount of material would give when arranged in any other form.

In the Iron Bridge, patented by the same inventors, and involving the same principles, the strength attained is practically illimitable. A model of this, 32ft. in length, is exhibited at the office of the Solid Lever Bridge Company, 46, Congress-street, which illustrates this. The advantages of a cheap, easily constructed, and strong wooden bridge are manifest to all—but those connected with railways are best aware of the immense importance of cheap and strong iron bridges. The obstruction of the western rivers by piers is so serious an impediment to navigation, that this invention becomes of the utmost importance, and comes just in time to solve the problem of how the railways are to cross the Upper Mississippi and the Ohio rivers, without navigation being destroyed. This is a matter of national interest, and is now engaging the attention of Congress. The new invention promises to reconcile the objection, and provide at a moderate cost the means whereby river navigation may be preserved, and railway communication across them be attained.

BRICKWORK IN CALCUTTA.

CALCUTTA brickwork has not the reputation of being first-rate; indeed, many people could be found who would say that it was essentially bad, or at least that that portion which is constructed under the auspices of the D.P.W. is bad, but that which is built by private persons or firms is much better. To the latter we ("Calcutta Engineers' Journal") would recommend a visit to Victoria-square, where two houses in course of construction have been severely injured by the heavy rain of April 25. The rain was preceded by a stiff north-wester, which, we must suppose, injured more or less the houses in question, but it was not till the heavy rain began to fall that the south walls of these houses were actually washed down, some of the so-called bricks being melted by the water. Of the bricks which have been brought to the site of the works, several are melted in the same way; and many, when dropped upon the ground from a height of two or three feet, broke into pieces like a bit of clay. The materials and workmanship of these houses is really disgraceful, and we hope that steps will be taken to have them properly examined, and, if necessary, pulled down, instead of allowing the Baboo, to whom they belong, to conceal with plaster a state of things which would be sufficient to deter any one from occupying the buildings. Two men were, we understand, severely injured, and were removed to the hospital; and, had it not been that at the time of the storm most of the men were working at the stables and servants' houses, the consequences would have been much more serious.

THE SCIENTIFIC WONDER.—Have you seen it? It magnifies 32,000 times. Price thirty-two stamps (post free), with book of full instructions. To be had only from A. McCulloch, Philosophical Instrument Maker, 18, Blucher-street, Birmingham.

N.B.—For further particulars, see Advertisement in this paper, page 1, column 2, headed "Scientific Wonder."—[ADVT.]

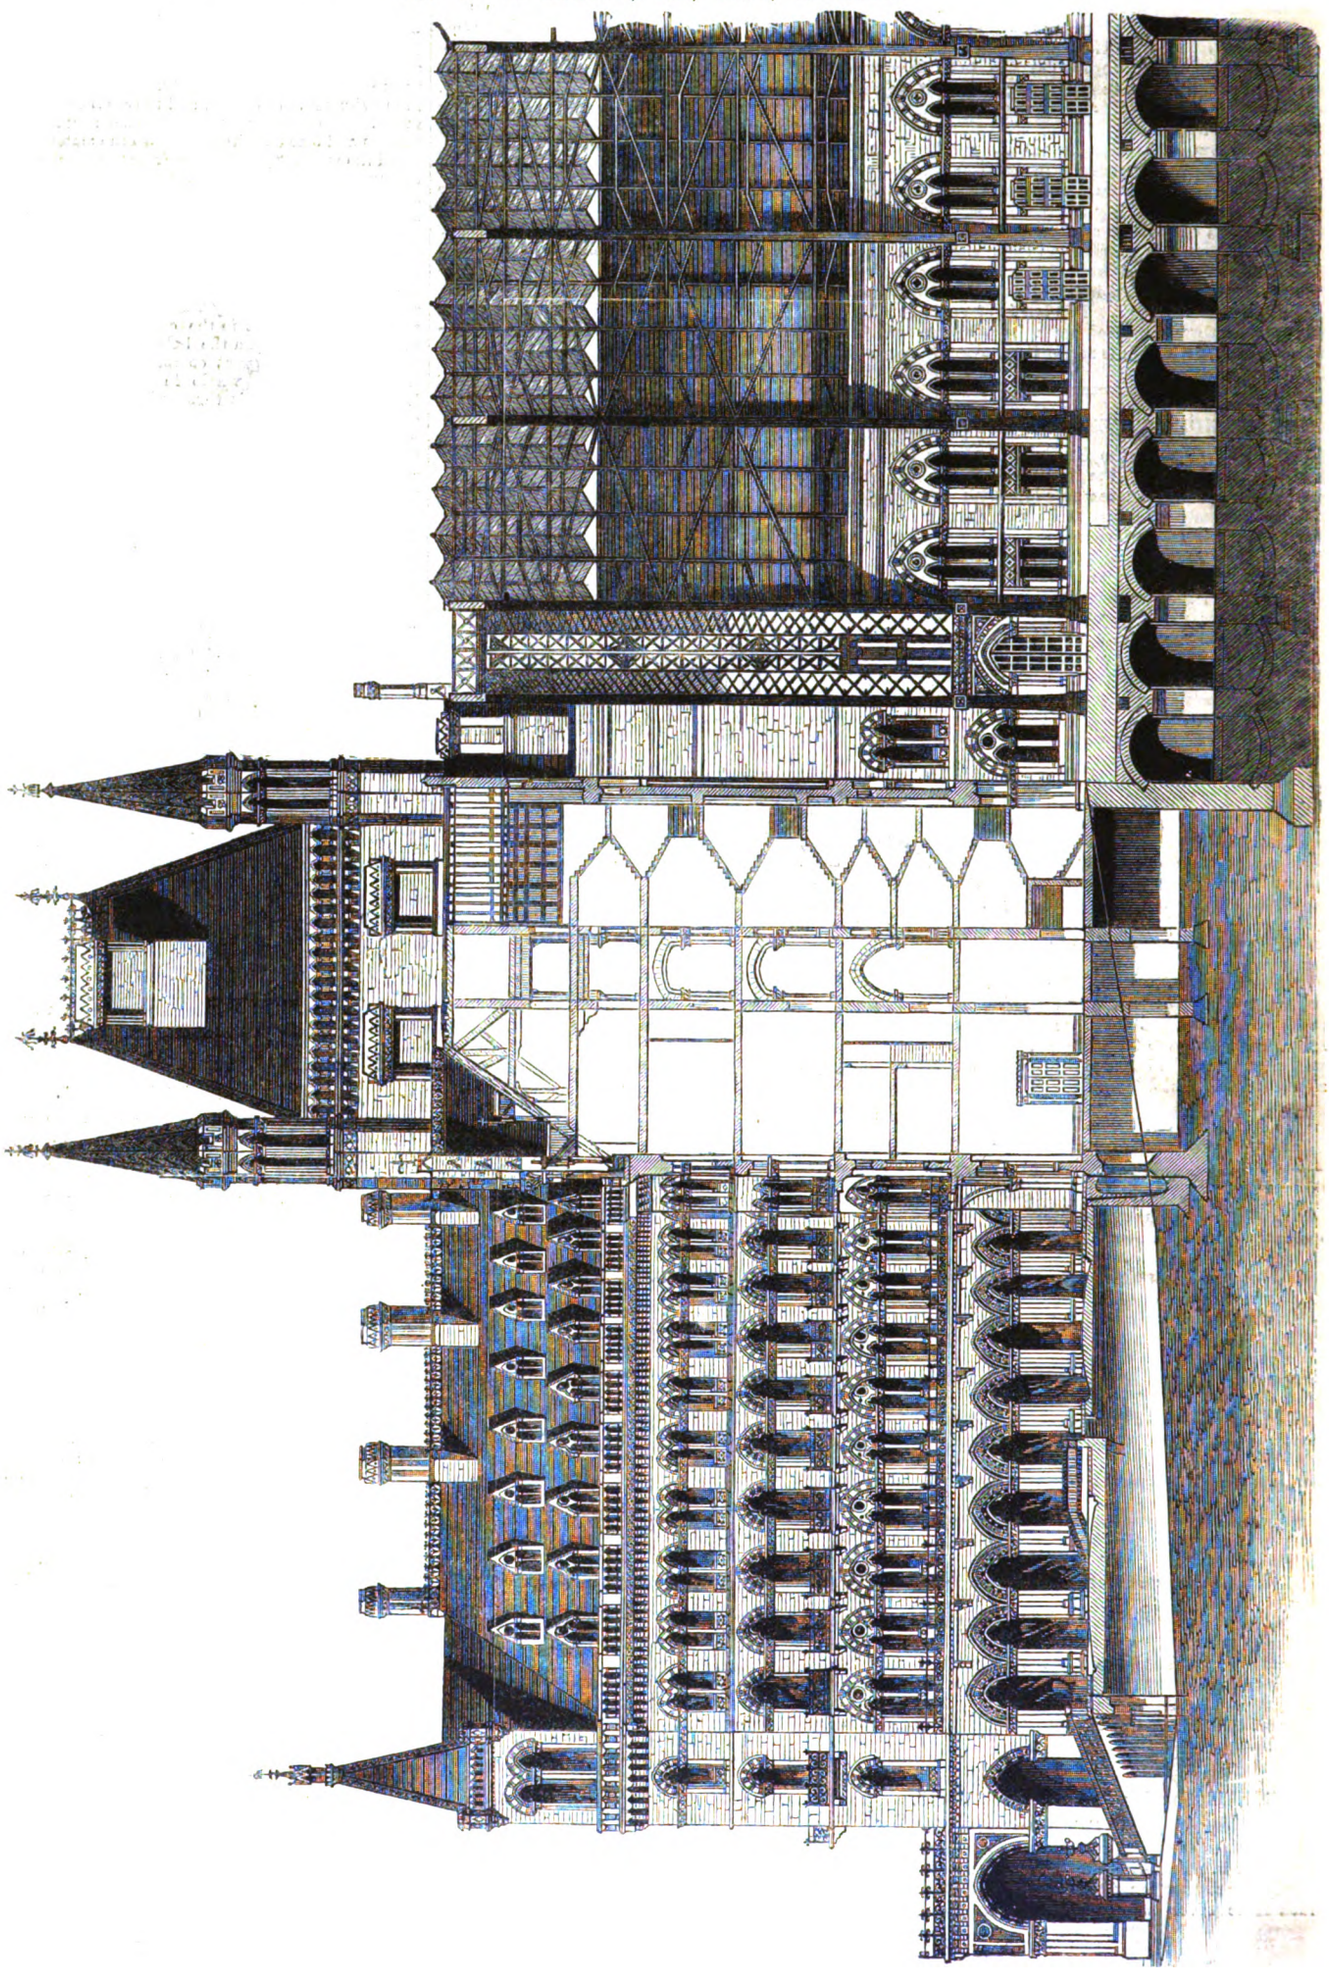
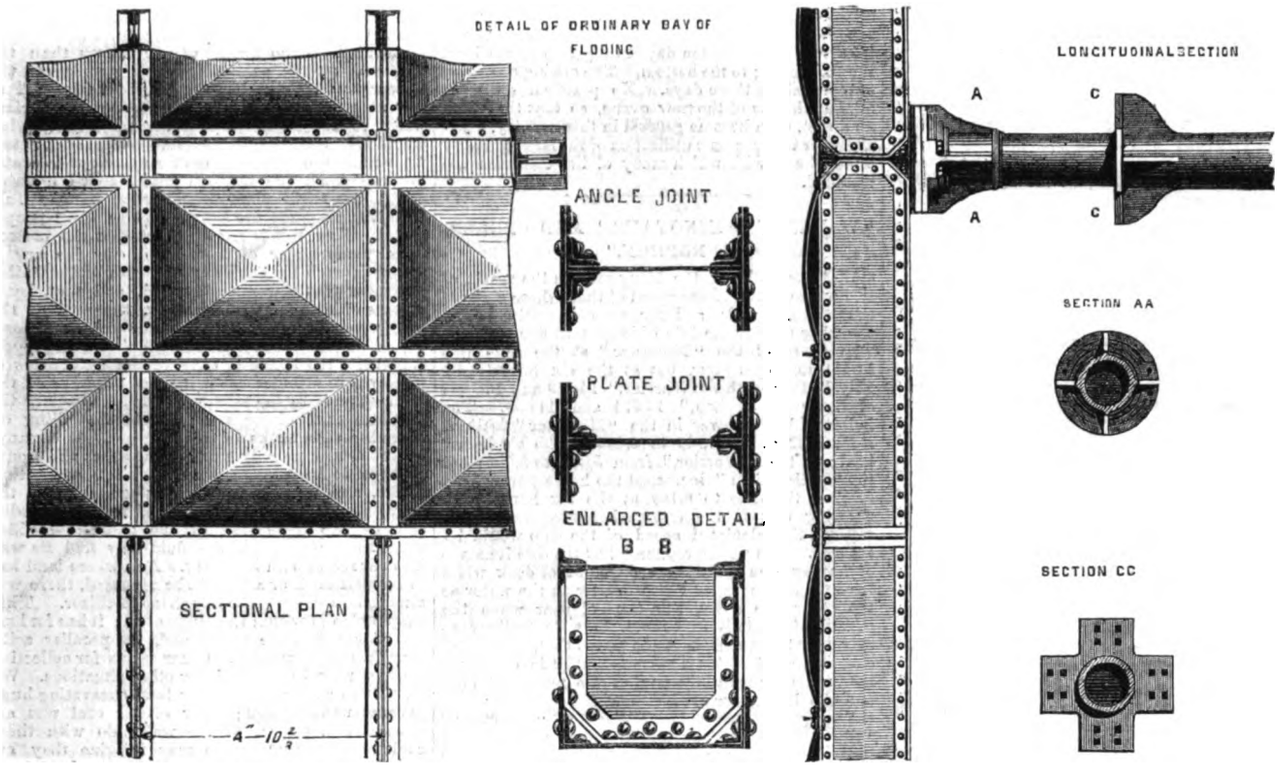
THE ST. PANCRAS STATION, MIDLAND RAILWAY EXTENSION—LONGITUDINAL SECTION THROUGH HOTEL.

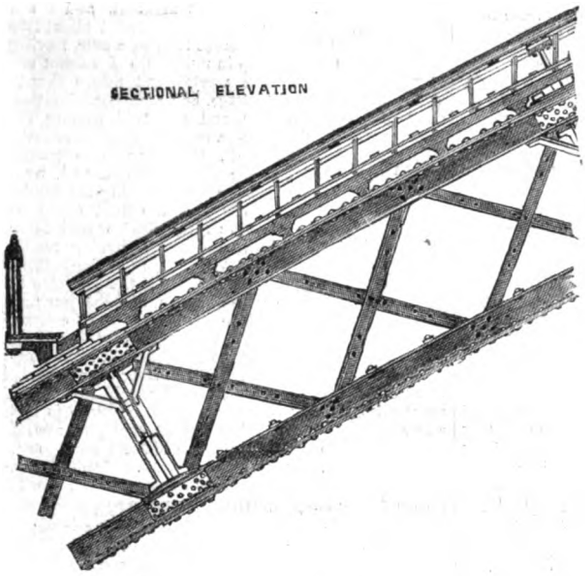
MR. W. H. BARLOW, C.E., F.R.S., ENGINEER.

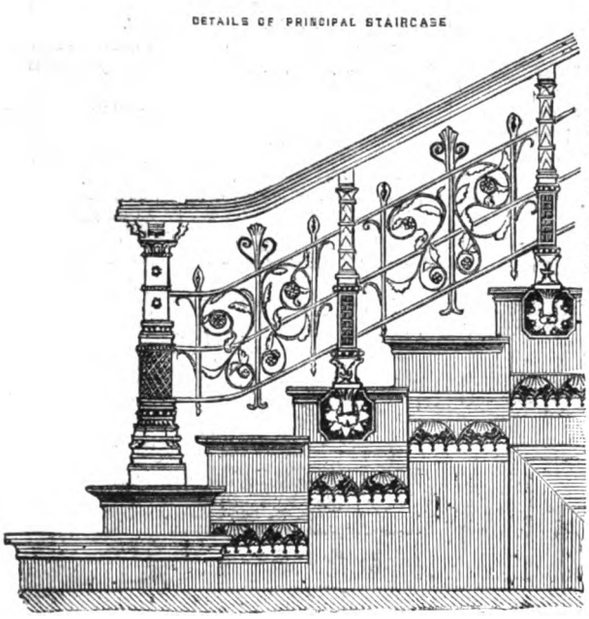


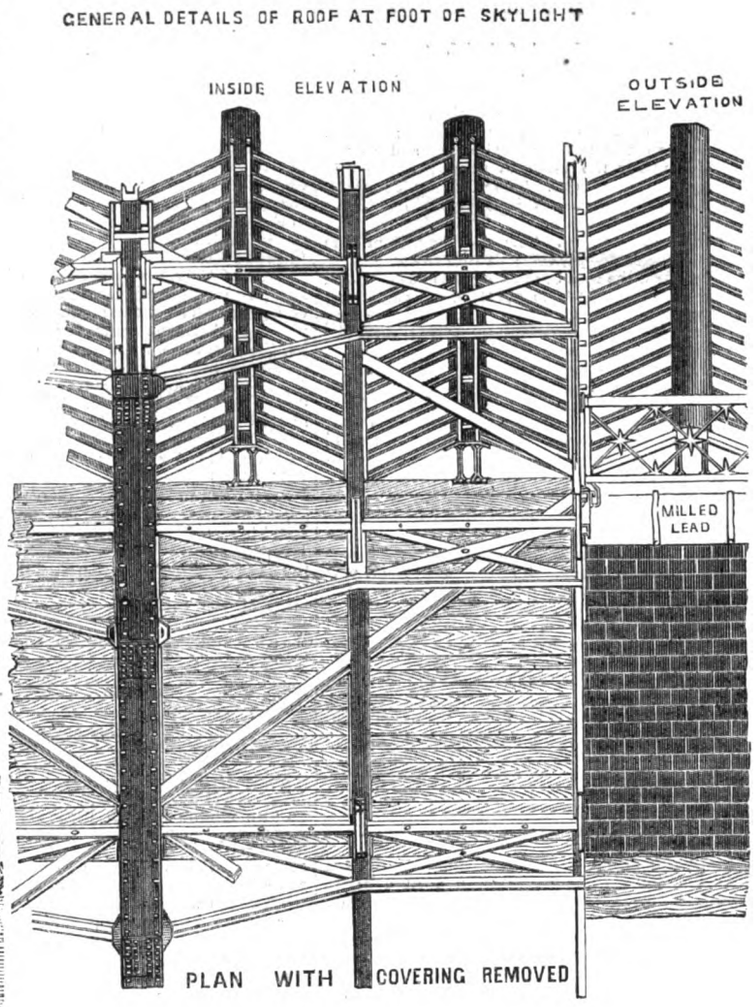
Digitized by Google

ST. PANCRAS STATION—DETAILS OF ROOF, FLOOR, AND FLOOR GIRDERS.









Digitized by Google

THE SAINT PANCRAS STATION, MIDLAND RAILWAY EXTENSION.

WE give this week engravings of the remaining details of the ironwork of this great roof, and the flooring, &c. The following are the dimensions of the flooring:—Height from floor level of cellar to underside of girders, 13ft. 6in.; height from floor level to bottom of column, 1ft. 6in.; total height of column 15ft.; diameter of column about 12in. clear. Wrought iron floor girders, 1ft. 9in. deep; width of flanges, 1ft. 2in. by 9-16in. thick; angle irons, 3½in. by 3½in. by ⅜in.; web plates, 5-16in. thick; span of girders, 14ft. 8in. Cross girders, 1ft. 9in. deep; flanges, 3½in. by 3in. by ⅜in.; angle iron web plates, 5-16in. thick. The main floor girders which connect end boxes of arched rib have an additional plate on bottom to take horizontal thrust of roof. Buckled plates, 5-16in. thick; size of rivets throughout, ¾in. diameter by 4in. pitch.

We also give an engraving of a longitudinal section through the hotel, and a portion of the adjoining roof. The new Midland terminus and hotel will be one of the largest of the metropolitan stations, the total extent of the site being about ten acres. The frontage will be in the Euston-road, not far from the present King's Cross station of the Great Northern Railway; the east side of the station borders on the Old St. Pancras-road; and the west in Brewer-street, which is diverted; the hotel building will occupy the corner between Skinner-street and the Euston-road. Seven streets have been diverted, and their intermediate houses, including St. Luke's Church, have been taken down for the new works.

The following is a summary of the present position of the work:—Fifteen out of the twenty-five main ribs are permanently erected. A portion of the work for the screen at the north end is completed. The woodwork and slating in the sides of the roof are finished for about 200ft. in length, and the sash bars are being fixed. The flooring is finished with the exception of a few lengths at the south end. The side walls are progressing rapidly. In conclusion, we beg to tender our thanks to the officials for their courtesy in facilitating our inspection and in affording us information.

UTILIZATION OF SMALL COAL.

AN improved form of coke oven has been devised by Messrs. Carves and Co., the object of which is to utilize the products of the coal, without deteriorating the quality of the coke produced; in fact, to produce a sound metallurgical coke, and at the same time utilize the products usually obtained in the manufacture of gas. The "Mining Journal" states that several works in Belgium have now adopted the invention, and the results obtained have been quite satisfactory. The first efforts in this direction were made by Messrs. Pauwel and Dubochet, who conceived the idea of utilizing the gas generated for the heating of the coke oven, or of employing the illuminating gas, and at the same time obtaining a good metallurgical coke, instead of the soft coke that had hitherto been obtained in the process of gas manufacture. They succeeded. After condensing the tarry, ammoniacal, and other condensible products, they employed the gas for heating the oven, and it then became a question whether the gas, deprived of its richer hydrocarbons, had still sufficient strength to give the necessary temperature to produce hard coke. The first experiments upon a large scale were made at Messrs. Carves' works, at St. Etienne, and it was found that when a large number of ovens were worked, so that the gas production and the heating should be regular, the process was satisfactory. As in the case of all new contrivances, the cost was at first very high, and some doubts were entertained of the economy of the arrangement, although its ingenuity could not but be admired. Step by step, however, Messrs. Carves overcame the obstacles, and by collecting the condensable products before the gas was ignited, and then devising a plan by which they could convert their old ovens at a cost of not more than £40 each, the process became a success. The new ovens are now arranged in groups of twenty-five each, which ensures great regularity in work and temperature. The importance of the new principle at collieries where a large quantity of small is made will at once be seen from a description of the process. The impure coal is first washed by the ordinary processes, and then pounded small by means of grooved rollers. This pounding is necessary when a good coke, of regular character, is required, and has the further advantage of much facilitating the distillation. A bed of pulverized coal is then formed in the oven, between 2ft. and 3ft. thick, and, of course, sloping down towards the doors, and the doors are then closed and luted with clay. The gas is then turned on and, upon entering the ovens, at once becomes ignited, for the temperature still remains high. The production of gas then commences, and passes off towards the gasometer, depositing its tar and ammoniacal compounds on its way. The Belgian oven and the bakers' oven are each said to be equally capable of conversion to the new system. The condensed ammoniacal products and tar run off into pits, and take from a week to ten days to separate themselves, the tar sinking to the bottom. The coking operation occupies about three days. No practical difficulty attends the use of the new ovens, so that they will, no doubt, soon become general in this country, especially for the economic utilization of the large quantity of small coal with which many of the collieries are troubled.

"WARRIOR," "MINOTAUR," AND "BELLEROPHON."

THE Controller of the Navy reports the result of a recent trial of the speed of these three ships at the measured mile, and for six consecutive hours' steaming outside the Isle of Wight, in fine weather. The speed of the "Minotaur" at the mile was 14·411 knots per hour, but at the six hours' trial only 14·165; of the "Warrior," 14·079 and 13·936; of the "Bellerophon," 13·874 and 14·053. The indicated horse-power in the "Minotaur" declined from 6,702 at the mile to 6,193 in the six hours' trial; in the "Warrior," from 5,267 to 5,092; but the "Bellerophon" increased the horse-power from 6,002 at the mile to 6,199 at the six hours' trial, showing that if the expected horse-power were realized the calculated speed of the ship would be assured. The "Bellerophon" had the disadvantage of having been twenty-one days out of dock when tried for six hours, or twice as long in the water as the other two ships, at a time of year when the growth of weeds is very rapid. The Controller considers that these experiments prove that, with good coal and good stoking, there is but little difference between the result of a trial at the measured mile and one lasting for six hours on the open sea; that the bad performances of the "Warrior," "Minotaur," and "Bellerophon" during their cruise last autumn arose from causes over which the designers of these ships had no control, and that any judgment on their qualities dependent on such records would have been illusory and misleading.

THE COTTON MANUFACTURE IN SWITZERLAND.

ONE of the most important industries in Switzerland is the spinning and weaving of cotton. Spinning is chiefly carried on in the eastern part of Switzerland. The "Society of Arts' Journal" informs us that the total number of spindles in all the establishments amounts to 1,600,000, of which 607,082 spindles are in 78 establishments in the canton of Zurich; 266,805 in 22 establishments in the canton of Argovie; 200,000 in 12 establishments in the canton of Glaris; 172,136 in 20 establishments in the canton of S. Gallo; 109,800 in 4 establishments in the canton of Zug; 50,400 in Svitto; 42,800 in Turgovie; 31,600 in the Grisons; 30,000 in Bern; 22,768 in Soletta; 10,000 in the canton of Bale; 16,120 in Scaffhausen; and 6,016 in the canton of Lucern. The total number of workpeople employed in this manufacture is about 15,400, and adding the number of managers, the clerks, and other employés, and the families of the workpeople, about 30,000 persons may be said to depend on this industry for their livelihood. The annual production of the spinning mills in Switzerland is estimated at 338,630 quintals. In 1857, the exports of cotton yarn was 18,504 quintals against 4,818 imports; in 1863, 53,836 quintals exports against 47,475 quintals imports; and in 1866, 35,738 quintals exports against 16,686 imports. This decrease must not be attributed to a smaller production, for during the years 1864, 1865, and 1866, the imports of raw cotton and the exports of cotton goods had largely increased; it should rather be attributed to the greater development of the cotton weaving during the last few years in Switzerland, which has tended to augment the consumption of cotton yarn, and for this reason a greater quantity has been imported.

Correspondence.

TOWN REFUSE PRACTICALLY UTILIZED.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—We have for long turned some of the refuse of the metropolis into building material, and allowed the more offensive sewage to flow into the Thames without extracting its useful properties as a fertilizer. Of course, everyone has his own idea on the subject, and are more or less interested in the various schemes proposed. As far back as I can remember—indeed, for centuries—house refuse in its natural state has been collected in suitable ash-pits, the offensive being deodorized by the inoffensive. I need not state that this plan is not at all suited for large inland towns, as the ashpits could not be formed without giving offence, and any other means adopted is not at all calculated for civilized life; dry-earth closets and pneumatic scouring is only suited for conveniences when placed in a garden or outhouse; the latter plan, is, of course, less suited for the insides of our houses than the dry-earth system, as, in this steaming weather, the vapours arising would be very noxious; indeed, at this season of the year, we cannot get sufficient water to scour our present arrangements: what would it be with the dry method? Were such fitted, we would be forced to deluge the system with water to keep down the noxious gases, and, I have no doubt, the small pipes would soon become full. However, all plans are very good in their proper places. Now, this is not a subject that the metropolis groans under of itself alone, for the cry is raised through the length and breadth of the United Kingdom that sewage is wasted, and that, by a process of manufacturing cheaply, the poor of the parishes could be maintained by the crumbs, I may say, falling from the rich man's table. In this respect it becomes the bounden duty of the authorities of all towns to manufacture a manure cheaply for the farmers, and, by the sale of this manure, relieve the destitution that ofttimes visit, from the falling off of trade on the banks of the Thames. To manufacture a manure only requires the ashes and house garbage to be conveyed to Barking, and other places, and by properly mixing or straining the sewage through large filtering and retaining media, and by the application of the partially purified water to meadow land, the fluid may find its way into our rivers with impunity. And where land has to be reclaimed, or a farm to be manured, there will always be a demand for this cheap fertilizer. This simple plan is within the range of all; it has for long been adopted in the north, and, for peculiar soils, forms a capital manure. Other plans for collecting sewage may be adopted for other situations. We have been busily engaged for long excavating huge caverns underground; many of our coal pits are worked out, and what are we to do with these cool storehouses? Some may imagine they are warm, but they are mistaken; a nicer, cooler retreat I could not wish at the present moment, and I am not writing at random, as I have crawled about two miles through a mine without turning a hair, having been ofttimes knee-deep in mud. So I cannot see any objection why these worked-out mines should not be filled up with sewage, and after consolidating or settling at the bottom, and the fluid finding its way up an upcast shaft at a considerably lower level than the downcast shaft, this invaluable guano would thus be collected and worked out, and, by a method of surface filtering and retaining the solids, at certain seasons of the year the fluid could be simply poured down, and, as the fluid would filter upwards instead of downwards, the filtering media being placed in the upcast shaft, and at the bottom of the pit covering a large area, thus the particles of sewage would settle at the bottom, and the purified fluid may find its way into our rivers. Of course, many, from interested motives, will raise the cry, it is not practical to do so—the sewage would contaminate other works. That is not so clear in my mind, but I am inclined to think that it would not. We must all remember that our last resting place is but a few feet below ground, and that coal pits, and, I may say, these used-up caverns of solid rock, are, on the average, sixty fathoms deep. Hoping you can give space for this somewhat long letter, I will return to the subject, with your permission.—I am, Sir, yours, &c.,

JOHN G. WINTON.

London, June 23.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—C. E. J.—M. E.—C. H.—J. W.—T. C.—W. D. R.—J. C. B.—F. G. S.—E. C.—L. S. B.—S. K. M.—B. J.—W. H. H.—J. N.—G. E. P.—J. H. R.—C. R.—G. B.—R. T.—F. C. L.—W. O. R.—F. W. B.—E. T.—J. N.—J. G. W.—Messrs. M. and Co.—G. W. H.—R. H. S.—N. L. L.—J. J. J.—Messrs. S. Bros.

Meetings for the Week.

MON.—Royal United Service Institution.—Captain E. A. Inglefield, R.N., on "Naval Tactics; with some Remarks on the Recent Experimental Cruising of the Mediterranean and Channel Squadrons." Captain Edmund Wilson, R.N., Will Exhibit and Explain certain Models Illustrative of his Plans for Armour-Plating, Working Heavy Guns, &c., at 8.30 p.m.

Naval, Military, and Gunnery Items.

PRINCE ARTHUR, who has received a commission as lieutenant in the corps of Royal Engineers, arrived at head-quarters, Chatham, on Tuesday, for the purpose of commencing his professional studies at the Royal Engineer establishment.

THE Council of the National Artillery Association have received from His Royal Highness the Prince of Wales his usual prize of £21, which will be added to the list for competition on Thursday, August 6, the day on which Her Majesty's prize will be shot for.

TO-MORROW—Saturday—the Lord Bishop of Chester will preside at the annual distribution of prizes on board the school frigate "Conway." The usual excellent accommodation, including a special boat, will be provided for visitors. Afterwards, his worship the mayor will entertain his lordship and a select party at dinner.

THE Prussian Government has authorized the Krupp establishment at Essen to execute a considerable order for cannons of cast steel on account of the Russian military administration, Russia being about to transform the whole of her artillery on the Prussian model. M. Krupp has gone to St. Petersburg in connection with this business.

THE standing orders for the volunteer artillery camp at Shoeburyness during the ensuing meeting of the National Artillery Association, the prize list, and order of firing, together with the terms of camp accommodation, &c., were issued on Saturday. Firing will commence on Tuesday, August 4, and continue till the 7th. The camp will be broken up on Saturday, August 8.

WE have to announce the death, from yellow fever, of Captain Blakeley, R.A., the inventor of the strengthened gun bearing his name, and which occurred on May 3, in Lima, Peru, whither Captain Blakeley had gone for the purpose of examining the condition of the guns furnished by him to the Peruvian Government, that did such good service during the engagement on May 2 with the Spanish fleet.

ON Saturday last two fine merchant vessels were launched at Rotherhithe, an event which, it is stated, has not occurred among the old shipbuilding yards of that district for about half a century. One of the vessels was a merchantman, called the "Mikado," 700 tons register, classed A1 for sixteen years at Lloyd's, and was launched from the yard of Mr. Walker, Lavender Dock, Rotherhithe. She has been constructed upon the composite principle, with the most recent improvements introduced into her build. The other vessel launched was the "Ruby," 266 tons register, built in the adjacent yard of Mr. Salisbury, at Rotherhithe, and is intended for the copper ore trade.

THE Admiralty lately effected the sale of an old ship out and out for £2,180. The fortunate purchaser extracted copper bolts, &c., therefrom £4,221 in value, which sum eventually was subtracted from the British exchequer "to repurchase the old stores bearing broad-arrow mark." The official comfort from this transaction, says the "Express," is that a clear gain still accrued to the Admiralty of £2,180, inasmuch as the copper bolts, &c., so repurchased for £4,221 would fully realize that amount in the open market. It would seem that, according to Admiralty arithmetic, a man who buys back a thing which he has given away is as well off as he was before he parted with it.

SEVERAL launches have recently taken place on the Clyde. Amongst others, Messrs. W. Denny and Brothers, of Leven, have launched an iron screw, named the "Abyssinia," built for the British India Steam Navigation Company. Her dimensions are 240ft. 6in. by 30ft. and 19ft. Her burden is 1,065 tons builders' measurement, and she will be supplied by Messrs. Denny and Co. with direct-acting surface condensing engines of 200-horse power nominal. Messrs. Wingate and Co, of Whitcinch, have launched a screw of 187 tons builders' measurement, named the "Celt," 100ft. by 20ft. and 10ft., and fitted with engines of 30-horse power nominal. Messrs. Randolph, Elder, and Co., of Glasgow, have launched a screw steamer of 1,339 tons builders' measurement, and 250-horse power nominal. This steamer, which has been named the "Biafra," is of the following dimensions:—Length over all, 285ft. 6in.; breadth, 32ft.; and depth (moulded), 20ft. 9in. The "Biafra" has been built for the African Steamship Company, and is intended for carrying mails to the West Coast of Africa. Her engines, which are being supplied by Messrs. Randolph, Elder, and Co., are on their patent compound high and low pressure principle, with surface condensers.

Miscellanea.

THE death is announced of Mr. G. Walker Arnott, professor of botany in the University of Glasgow.

THE Newfoundland seal catchers report having already secured 455,000, or upward of 1,000,000 dollars worth of seal this season.

THE lightning, during a recent storm, is stated to have melted upwards of 1,000ft. of telegraph wire in Illinois, in America.

AT Pilcot, in Hampshire, a tom-tit has built a nest in the post-office letter-box. It laid twelve eggs in less than a fortnight, and hatched nine of them.

THE curators of the University of Edinburgh have resolved to postpone the election of a principal till July 6. Dr. Calderwood, of Glasgow, has been elected to the chair of moral philosophy.

SPRING terminated on Sunday morning at 18min. past 4, and summer began astronomically, although the last-named season has anticipated the official date in bringing its characteristic heat.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending June 20, was 2,421; total number since the opening of the museum, free daily (May 12, 1858), 1,814,454.

A PROJECT is said to be on foot for holding a great demonstration at the Crystal Palace on an early day in July, "as a combined public manifestation of all classes on behalf of the scriptural faith restored to England at the Reformation."

THE Burlington and Missouri Railway is now finished to Afton, within a hundred miles of Omaha. Contracts will soon be taken for the construction of the road to that point, to be completed by July 1, 1869.

MR. GLADSTONE, as president of the Statistical Society, has selected from the council the following gentlemen to be vice-presidents:—Colonel Sykes, M.P., Dr. W. Farr, Mr. James Heywood, M.A., and Professor J. E. Thorold Rogers.

FROM a statement published by the Belgian Minister of Finance, the value of the 25-franc gold coins issued by the mint of that country in 1867 was 26,826,140 francs; the 5-franc pieces amounted to 18,465,720 francs; and smaller money to 14,737,000 francs.

THE "New York Evening Mail" says that the largest nail manufactory in the United States is located at Bontoon, N. J. The building covers six acres of ground. 1,500 cords of chesnut-wood are consumed each year in making kegs in which to pack the stock.

A CORRESPONDENT of the "Nord" mentions that the Emperor Napoleon is very fond of taking solitary walks in the Forest of Fontainbleau, and making experiments with Norton's tube well, which has been used with so much advantage in Abyssinia. It is said that his Majesty has discovered by its means a sulphur spring in the forest.

THE "British Workman" for July contains a highly interesting memoir of the late Lord Brougham, not in either of his capacities as the student of science, the writer, the lawyer, the orator, or the politician, but as the friend of the working classes. To the memoir is prefixed a splendid page portrait of his late lordship.

THE Society of Engineers will visit the Chatham Dockyard extension works on Friday next, July 3, by permission of the Lords Commissioners of the Admiralty. A special steamer has been engaged for the conveyance of the members and their friends, leaving Old Swan pier at 9 a.m., and Blackwall at 10 a.m. on that day.

A CATASTROPHE to art has occurred at the Palace of the Luxembourg in Paris. The plasterwork of the fine dome of the library, painted by Eugene Delacroix, has fallen down, and broken to pieces. The fragments have been carefully taken up and conveyed to one of the studios of the Louvre, where Count de Nieuwerkerke is having them placed together again.

THE trials of ploughs and field implements and the preliminary trial of steam cultivators in connection with the Leicester meeting of the Royal Agricultural Society will commence on Thursday, July 9, and will continue till Tuesday, July 14, on farms in the parishes of Knighton and Aylestone, about a mile south of the show-yard. The general meeting will commence on Wednesday, July 15.

THE visitors to the South Kensington Museum during the week ending June 20, 1868, were—On Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 8,032; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,875. National Portrait Exhibition, by payment, 2,093; total—12,000. Average of corresponding week in former years, 12,386; total from the opening of the Museum, 7,462,557.

From the report of the Auditor General of the State of Pennsylvania for the year 1867, we learn that more than two-thirds of the total tonnage of the railways of the State last year consisted of mineral products as follows:—Anthracite coal, 15,482,140; bituminous coal, 4,931,378; petroleum, 834,624; pig iron, 628,779; railway iron, 358,950; other iron or castings, 349,227½; iron and other ores, 1,501,564½; lime and limestone, 735,654½; total, 24,822,317½.

FROM 1857 to 1866, the length of telegraphs in British India increased from 4,162 to 13,390 miles. In the latter year the total expenditure for telegraphs amounted to £253,191, £48,067 of which was for cost of construction, £163,392 on account of working and maintenance, and £41,732 spent in England for stores, freight, &c. The total receipts for the same year amounted to £112,944, £101,306 of which were derived from private messages and other sources, and £11,638 from service messages of all kinds. There has been a large progressive increase of receipts year by year since 1857, except in 1860, and there are now 172 offices open throughout the country for the use of the public.

THE "U. S. Railway Journal" states that the Ringgold (Pa.) Iron Company proposes, under a patent which they hold, to manufacture blooms direct from the ore. One furnace erected last summer has been in successful operation ever since, and with the most flattering results. The company is now erecting five additional furnaces, making six in all, upon land lately purchased at Ringgold, in Jefferson County. The works will be erected contiguous to the Little Schuylkill Branch of the Reading Railway. The tract of land owned in connection with the works contains an abundance of iron ore and limestone.

A SERIOUS explosion of gas occurred at the Theatre Royal Preston, on the evening of Tuesday week. The stage foot-lights are supplied with oxyhydrogen, and this mixture of gases is kept in bags provided specially for the purpose on one side of the stage. Just previous to the commencement of the performance, a man named Catterall and some others were engaged in preparing for the ignition of the foot-lights by arranging the gas bags, &c., when two of them suddenly exploded. Catterall was blown some distance; his clothes were torn in several places, and he was considerably shaken and cut about the chin and face

ON Friday last, the Metropolitan Board of Works received tenders for the construction of that portion of the Thames Embankment (North) between the eastern end of the Inner Temple, and Blackfriars-bridge. They were as follows:—Messrs. Hill and Keddell, £179,000; Thomas E. Ridley, £173,500; Messrs. Eckersley and Bayliss, £159,000; Messrs. Jennings and Co., £146,659; T. Pearson, £144,000; Thomas Docwra and Son, £142,000; Messrs. Brassey and Co., £137,900; Messrs. Kelk, Waring Brothers, and Lucas, £127,000; W. Webster, £126,500. Mr. Webster's tender was accepted.

THE "Ararat Advertiser" records the progress of destruction of forests in that district as follows:—"In another year there will not be one of these trees in the whole district that has not been utterly destroyed by barking. Around the town of Ararat, and for miles around, the various centres of population in the district, there is hardly such a thing as a wattle tree to be seen. Within the last fortnight we believe not less than 500 or 600 tons of wattle bark passed through Ararat in waggons returning from up-country trips."

A NEW local industry, in the shape of a bone mill, has been introduced into Gipps Land. The want of a fertilizer more highly concentrated and richer in ammoniacal salts and the inorganic alkaline substances that give luxuriance to vegetation than the descriptions of manure hitherto available, has long, remarks the "Gipps Land Times," been experienced by the numerous farmers and general produce growers; and as it is universally confessed that the various preparations of bone manure possess combined these valuable properties, the erection of the requisite machinery for manufacturing the article will doubtless be highly appreciated.

GEOLOGICAL change appears to be more rapid, or more obvious, along the coasts of China and Japan, and the country to the northwards, than in other parts of the world. The changes that have taken place within the memory of man are almost incredible. The land is elevated, and gains on the sea. Mr. Bickmore, an American traveller, has made careful observations from Canton up to the mouth of Amoor river, and his general conclusion is that the facts, taken in connection with the dry beds of friths and bays along the Siberian borders of the Arctic Ocean, and the remnant of the old gulf that once washed the eastern flank of the Ural, enable the geologist to form an idea of the large increase of the Asiatic continent within a comparatively recent period.

A CORRESPONDENT of the "Illustrated Australian News" directs attention to a discovery of considerable importance—the existence of an extensive pearl fishery on the north-west coast of Western Australia. He describes the fishing ground as stretching along the coast no less than 1,000 miles. "There had been upwards of 60 tons of pearls obtained up to December, when circumstances obliged me to leave," he writes, "and these were purchased on the spot at the rate of £100 per ton. The banks at Perth will advance £100 per ton, not including the inside pearls, which are valued from £1 to £20 each. When I left the fishery there were about thirty men engaged in pearling. My shells have not reached Melbourne yet, but I will soon have them to submit for examination. I have also a small portion of shells worked, which I will also be glad to have inspected; and I will be glad to furnish any information upon the subject required."

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3493
BUILDINGS AND BUILDING MATERIALS—None.
CHEMISTRY AND PHOTOGRAPHY—None.
CULTIVATION OF THE SOIL, including agricultural implements and machines—3500
ELECTRICAL APPARATUS—None.
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3481, 3489, 3504
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—3499
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—3486
GENERAL MACHINERY—3490, 3494, 3497
LIGHTING, HEATING, AND VENTILATING—3487
METALS, including apparatus for their manufacture—3502
MISCELLANEOUS—3484, 3485, 3491, 3493, 3496, 3498, 3501, 3503, 3505
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—3482, 3488
SHIPS AND BOATS, including their fittings—None
STEAM ENGINES—3495
WARFARE—3492

3466 A. C. STERRY. *Improvements in engines worked by heated air or gas.* Dated December 5, 1867.

This invention has for its object the production of motive power by means of air or gas alternately heated and cooled in separate chambers, and always maintained at a pressure greater than that of the atmosphere, thereby admitting of an engine being driven by air or gas at a lower temperature than when the air or gas is admitted to the compressing pump at the atmospheric pressure, less heat being generated in this pump at the same pressure.—Patent abandoned.

3467 M. TILDESLEY and J. BIRD. *Improvements in annealing furnaces, and in apparatus to be employed therein, parts of which improvements may be applied to certain other descriptions of furnaces and fires.* Dated December 5, 1867.

This invention consists in constructing the firebars of annealing furnaces in such manner that they will slope downwards from front to back. At the bottom of the bars is a chamber some distance from the bottom of the hearth to receive the cinder, which can be withdrawn from the front of the bars; the open front above the bars can be closed up either with slack or with doors, or in any other suitable manner; and by thus constructing the firebars slack may be consumed instead of large coal.—Patent abandoned.

3468 T. J. LEIGH. *Improvements in furnaces, and in effecting the combustion of fuel therein.* Dated December 5, 1867.

This invention relates to a former patent, dated June 12, 1866 (No. 1594). In the specification of this patent the patentee described a method of burning certain combustible materials (such as coal dust, coke, coke dust, charcoal, wood, hydrocarbons, and gases) on and in a stratum, bed, or bath of molten iron, or other metal. In performing the present invention the patentee forms a chamber lined with firebrick, or other refractory substance, which chamber is closed in or arched over, except at two places on opposite sides, where apertures are formed, the one for supplying fuel, and the other for the exit of the flames. This latter aperture leads to the bed of a puddling or melting furnace, or around the sides or through the tubes of a boiler, where the heat is utilized. The chamber is formed with a partition, diaphragm, or hanging bridge which descends from the crown or roof of the chamber to a certain distance from the bottom. Molten slag or molten glass, or a bottom or bed plate of metal covered with molten slag or glass, occupies the bottom of the chamber to a level of a few inches below the partition or diaphragm. The chamber is thus separated into two compartments communicating with one another through the passage between the lower side of the diaphragm and the surface of the molten matters. The side of the first or feeding compartment is either vertical or inclined, and through this side he introduces a blast of air from a fan or other blowing apparatus. This may enter by one tuyere, but he prefers to make it enter by numerous tuyeres at suitable levels. At the top of this compartment he places a fuel hopper, where, by suitable mechanism, the fuel is passed as required for combustion into a shoot, and made to fall upon an inclined metal plate, and thence into the chambers. A stream of cold air is made to play upon the surface of the inclined plate so as to keep it cool, and assist the descent of the fuel into the feeding compartment. The fuel in descending through the compartment is mixed with the air entering by the tuyeres, and being kindled a continuous sheet of flame is thus made to pass over the surface of the molten matter into the other compartment of the chamber, where it issues to the furnace with which it is connected.—Patent completed.

3469 P. G. L. G. DESIGNOLLE and J. CASTHELAZ. *Improvements in the manufacture of explosive and fulminating powders.* Dated December 5, 1867.

The patentees claim the application in the manner described of picrate or carbazotate of potash, of the salts formed by picric or carbazotic acid, of the derivatives of this acid, of their salts, and of the acid itself to the manufacture of powders. They also claim the several compounds described.—Patent completed.

3470 E. A. PONTIFEX. *Improvements in condensers.* Dated December 5, 1867.

The patentee claims constructing surface condensers with pipes bent round so as to form limbs of equal or nearly equal lengths, as described. He also claims the combining surface condensers having pipes over which water is caused to trickle with injection condensers, as described.—Patent completed.

3471 S. GOLDSTEIN. *Improvements in various portions of ladies and gentlemen's wearing apparel.* Dated December 6, 1867.

The novelty of the invention consists in constructing a lady's skirt, when required as a waterproof skirt, in two parts, the upper portion being composed of any suitable material, to which is attached, by buttons or other similar fasteners, the lower portions of the skirt, which is composed of waterproof material, the reverse side of which may be ornamented so as to be worn in fine weather as an ordinary skirt.—Patent completed.

3472 J. W. KENYON and R. A. ARMISTRAD. *Improvements in safety apparatus for steam boilers or steam generators.* Dated December 6, 1867.

This invention is designed for the purpose of lessening the risk of the explosion of steam boilers, arising from a deficiency of water in the said boiler, and consists in an improved apparatus intended to discharge a portion of the water or steam, or of water and steam, into the furnace or furnaces at such times as the "water level" in the boiler is lowered to a dangerous extent.—Patent completed.

3473 J. DURRANS. *An improved material or composition to be employed for covering or coating the interior surfaces of moulds, crucibles, or ducts, previous to their receiving the molten metal in the process of casting, and for other purposes.* Dated December 6, 1867.

This composition consists of carbonized coal or graphite, which may be specially carbonized and pulverized or reduced to powder, and mixed with water or suitable liquid to make it into a paste or solution; or the carbonized coal may be obtained from the interior surface of retorts which have contained coal, and upon which it becomes encrusted. This solution or mixture is to be applied to the surfaces of moulds or channels requiring protection from the molten metal, and allowed to become dry and hard, when it forms a hard heat-resisting surface, and imparts to the casting a fine surface or finish, and when applied to the ducts or channels it assists the flow of the metal therein, and prevents adhesion of "slag" or refuse to the sides thereof.—Patent completed.

3474 C. KERRY. *Improvements in the combination of materials to be used for filtering liquids.* Dated December 6, 1867.

This invention consists in the combination of certain materials for the filtration of liquids, and by the employment of which that operation can be performed with great efficiency. A sheet of linen, calico, or any other textile or felted material possessing the requisite degree of strength and porosity or permeability, is covered with a layer of paper pulp, such as that of which ordinary filtering paper is manufactured, there being no size mixed therewith. Adhesion between the pulp and the fabric is obtained by subjecting the sheet or fabric so coated as before mentioned to the pressure of a hot roller. For the filtration of water containing organic impurities, charcoal in a pulverized state may be combined with the paper pulp, and in like manner other substances which are capable of acting upon the liquid or liquids under treatment, according to well-known chemical principles, may be beneficially combined with the pulp.—Patent abandoned.

3475 W. N. NICHOLSON. *Improvements in machinery for spreading grasses, part of which improvements are also applicable to machines for cutting and collecting grasses.* Dated December 6, 1867.

The first part of this invention relates to machinery for spreading grasses. On the axle of the machine, whether such axle be concentric or eccentric, the inventor mounts an eccentric cylinder or cylinders, and on the external part of such eccentric cylinder or cylinders the fork barrels are made to revolve. By moving such eccentric cylinder or cylinders round the axle, the fork barrels are thrown for either the forward or reverse motions, or are disengaged for travelling, at the same time the height of the fork barrels from the ground can be varied when it is desirable to do so. He also makes the ironwork by which the horse shafts are attached to these machines of channelled or grooved iron. The second part of the invention is for improvements in the travelling wheels of machines for cutting, spreading, or collecting grasses or corn. For the purpose of giving the wheels a firmer bite on the ground, so to increase their power of driving the machinery connected with the same, he makes projections either at right angles, or any other angle or curve, on the edge of the peripheries of the wheels, or makes such peripheries laterally of a zigzag form.—Patent abandoned.

3476 H. J. F. H. FOVEAUX. *An improved construction of cell for galvanic batteries.* Dated December 6, 1867.

This invention consists in constructing cells for galvanic batteries in such manner that, when the cell is in one position the fluid surrounds the battery metals, and when the cell is reversed, the fluid is out of contact with the metals.—Patent abandoned.

3477 F. ROPER. *Improvements in apparatus for driving straw elevators.* Dated December 6, 1867.

The patentee claims applying at the corner of a straw elevator, or, it may be, of a thrashing machine, guide pulleys which are adjustable up and down, so that their position may be suitably intermediate of the driving and the driven pulleys, and so that their axes may be set at right angles to the driving band as it passes on to them. He also claims the application to the straw elevator of a swinging bracket with guide pulleys upon it, so that, by the movement of the said bracket on its centre, the guide pulleys may be transferred from one side of the machine to the other, as may be required. He also claims the general arrangement of the apparatus, substantially as described.—Patent completed.

3478 J. EVANS. *Improvements in couplings for railway trucks.* Dated December 6, 1867.

By this invention the trucks can be coupled without the person effecting the coupling placing himself between the trucks. On that end of the truck which carries the links by which one truck is connected to the back of the next one, the inventor fixes an axis, the said axis being parallel with the end of the truck, and at about the level of the bottom of the truck. The axis has a length somewhat greater than the width of the truck, and has a lever or handle at either end, by which it can be partially turned. Besides a rotary motion, the axis has a sliding motion, that is, a motion in the direction of its length. One or more coiled springs surrounding the axis bring it back to its normal position after it has been moved in the direction of its length. Near the middle of the axis two arms are fixed, the said arms being of a length nearly equal to the length of the coupling chain, or series of links, one of which is hooked to the hook of the next truck. The arms are jointed in the middle, the joint allowing the ends of the arms to rise out of the plane of the other part, but not to descend beyond the line of the other part. These arms are situated respectively on either side of the coupling links, and the extreme ends of the arms are connected with the last link by means of pins on the sides of the link engaging in slots in the ends of the arms. In using the coupling, the axis is turned by one of the levers or handles, and the arms raised somewhat beyond a horizontal position, the axis being at the same time made to slide a short distance in the direction of its length. The end link is thereby raised to a greater height than the hook with which it is to be coupled, and in rising is sufficiently on one side of the said hook to escape it. By now allowing the axis to slide back into its normal position, the link is brought over the hook, and on depressing the handle or lever it falls on to and engages with the said hook, and the coupling of the trucks is complete.—Patent abandoned.

3479 R. JONES and J. ABRAHALL. *Improvements in the manufacture of hollow metallic seamless spheres and ornaments.* Dated December 6, 1867.

This invention has for its object the manufacture of the said spheres and ornaments of thinner metal than can be employed in manufacturing them according to the ordinary method. The invention is also applicable to the manufacture of hollow metallic spheres and ornaments of other metals than gold.—Patent abandoned.

3480 R. W. LINDSAY. *Improvements in machinery for the manufacture of brass and copper tubes.* Dated December 6, 1867.

Here two or more brass or copper tubes can be simultaneously drawn at one draw bench. In arranging or combining the parts of machinery for the simultaneous drawing of two brass or copper tubes, the inventor affixes to the chain by which the drawing is effected a block or waggon, in which two recesses are made for the reception of two pairs of clips or forceps, which grip the mandrils during the drawing process. Or, when tubes are drawn without mandrils, he employs compound plyers or forceps of the kind hereinafter described. The draw plates which he employs consist of square plates of steel, having holes in them of the ordinary kind, the holes through which the two tubes are drawn being made in separate plates. These plates are supported in an upright in a groove in which the said plates are introduced and fixed. The plates have a slight play in the groove, in order to allow them to take an exact position with respect to the clips or forceps during the drawing. The compound plyers or forceps have a movable tongue or projection inserted between their blades. In using these plyers or forceps the movable tongue or projection is placed between the two tubes, and the blades of the forceps or plyers are placed on the outer sides of the two tubes. On closing the said forceps, and fixing them to the drawing clam, the tubes to be drawn are gripped between the blades of the plyers or forceps and the movable tongue or projection. The tubes to be drawn having been passed through the holes in the draw plates, and the tubes or mandrils gripped by the clips or plyers or forceps, the drawing is effected in the ordinary manner.—Patent abandoned.

3481 C. BRAZIL. *Improvements in machinery for sizing cotton and other yarns.* Dated December 7, 1867.

The invention is applicable to the sizing machines known as "tape legs" and "slashers," and consists in an improved combination of a revolving cylindrical brush with one or more revolving smoothing guard rods, a revolving presser rod, and one or more revolving opening rods. The yarn on leaving the size box passes over the first guard rod, then over the brush and under the presser rod, then over the second guard rod, and then it passes to the drying cylinder, being divided into two or more parts by the opening rod or rods. The depth of penetration of the bristles of the brush through the yarn is governed by a regulating set screw passing through the lever in which the press rod revolves.—Patent abandoned.

3482 P. R. HODGE. *Improvements in machinery and apparatus for heating and forming of metals.* Dated December 7, 1867.

This invention relates, firstly, to a peculiar construction, arrangement, and conformation of apparatus for reheating railway wheel tyres, more especially that form of tyre used on a railway wheel patented by Brookes, October 7, 1859 (No. 2286). This peculiar form of wheel tyre has first to be shrunk on to the wheel rim, and afterwards a lip has to be turned down over the bevel part, making the tyre perfectly secure without the use of bolts or rivets. The improved method is to reheat this lip by the agency of a series of compound jets of carburetted hydrogen gas and common air in their proper equivalents, or by any other combination of hydrocarbons in connection with superheated steam or gas, to produce the most intense heat. These jets are brought to bear and impinge on the lip around the periphery.—Patent completed.

3483 R. B. JONES and W. POWELL. *Improvements for the prevention of incrustation in steam boilers.* Dated December 7, 1867.

The patentees claim attracting or collecting the electricity generated in the interior of such boilers, and conducting it to their shells. Also the generator for the prevention of incrustation of steam boilers having conductor points proceeding from its circumference towards the centre, and platina wire or band at its periphery.—Patent completed.

3484 J. B. MORRISON. *Improvements in the construction of operating chairs, more especially designed for dentists, parts of such improvements being applicable for other purposes.* Dated December 7, 1867.

This invention consists, chiefly, first, in a novel mode of raising and lowering a chair or other article; second, in certain novel means for adjusting and securing the same at any required angle; third, in constructing an operating chair with arms adjustable in reference to the seat of the same; fourth, in a novel mode of adjusting the back and arms with reference to the seat; fifth, in the novel construction and manner of adjusting the head rest of an operating chair; and, sixth, in so constructing and combining these various parts in a chair as to enable it to be adjusted to adapt it to adults or children.—Patent completed.

Digitized by Google

3485 O. BARRETT and H. LEGGOTT. *An improved knife cleaner.* Dated December 7, 1867.

This invention consists in the employment of one, two, or more cylindrical brushes having leather, buffalo hide, or other suitable substance introduced betwixt the bristles, such brush or brushes being enclosed in a box or casing, so as to be capable of receiving rotary motion. Also in having pads pressed by springs into contact with the surface or surfaces of the said brush or brushes, and removed from contact by cam, lever, or other suitable means for introduction or withdrawal of the knives.—Patent completed.

3486 J. BLAKEY and H. B. FOX. *Improvements in collars, cuffs, anklets, belts, and other like articles of wearing apparel.* Dated December 7, 1867.

The articles made according to this invention may, in short, be said to consist of a flexible picture frame and picture, the edge of the frame being sufficiently flexible to allow a slip or leaf (which is really the representative of the picture) to be easily fitted in and removed, the former being so shaped as to hold the latter securely in position when the article is in use.—Patent completed.

3487 J. PARTINGTON. *Certain improvements in the method of heating buildings, and in the apparatus connected therewith.* Dated December 7, 1867.

This invention consists in the use and application of an air chamber or vessel or vessels situated behind the fire, so as to form the back of the grate in cellars, kitchens, or other suitable positions. The chamber may be of any convenient form, and made of metal, brick, fireclay, or combinations thereof, and from below it is supplied with cold air by means of a pipe and regulating valve, and on the air becoming heated by the action of the fire it ascends up a pipe applied to the upper part of the chamber, which extends up the chimney, and is carried into the various rooms at different heights by branch pipes, which may be opened to allow the hot air to escape into the room, or the heat may be obtained by radiation only.—Patent abandoned.

3488 J. RAE and G. MILLER. *Improvements in railway wheels.* Dated December 7, 1867.

This invention is not described apart from the drawings. —Patent completed.

3489 W. CLISSOLD. *Improved machinery for preparing fibrous substances for spinning.* Dated December 7, 1867.

This invention consists in the applications to the feeds of carding engines or preparing machines of certain means for neutralizing the contractile force of the fibres as they are presented to the feed rollers, thus insuring a more uniform breadth of feed than has heretofore been obtained.—Patent completed.

3490 J. BEATTY. *A new or improved candle-dipping machine.* Dated December 7, 1867.

The patentee claims the general arrangement and combination of parts for dipping candles, whereby they are alternately dipped at each end of the machine, and especially the railway principle as applied to the dipping of candles, viz., the motion of the candles to and from the dipper by any kind of carriage or carriages on fixed declining rails, whereby the candles become cool in their transit, and ready for fresh dipping, substantially in the manner specified.—Patent completed.

3491 C. M. BARKER. *Improvements in socket and flange spigot pipes.* Dated December 7, 1867.

The patentee claims, first, the combination of screwed flanged spigots, and their flat or taper sealing surfaces, with internal screwed sockets, and their corresponding taper cavities, for the purpose of making tight joints in gas and water pipes, by enclosing and compressing any cement, soft lead, or other equivalent material between the junction surfaces, substantially as described. Second, the use of hexagonal or flat-sided bands cast on the pipes for the purpose of presenting flat surfaces, which, together with the back or check nuts, effectually provide for screwing in service pipes without danger of leakage, substantially as described.—Patent completed.

3492 R. WARRY. *Improvements in the construction of breech-loading firearms.* Dated December 7, 1867.

This invention consists in certain improvements in the construction of breech-loading firearms in which the breech-block is hinged at the side of the barrel, and in which central-fire ammunition is employed. The breech-block is of the description known as a "solid" breech-block, and is fixed to a spindle or pin which is mounted in suitable bearings formed on or attached to the exterior of the barrel and breech-plate, and in which it is free to move, thus forming a hinge for the breech-block. The hinge is, by preference, placed on the side of the barrel opposite to that on which the hinge of the breech-block is placed in the "Snider" system of breech-loading firearms, but it may, if desired, be similarly placed; a hole is drilled or formed through the centre of the breech-block, in which is placed the striking piston, or that by which the centre of the cartridge head is percussed, the same working in a direct line coinciding with the axis of the barrel, whilst at the same time it performs the office of a locking bolt for the breech-block. The rear end of the striking piston is formed with a conical base, which is capable of fitting into a corresponding recess formed in the centre of the breech tang or plate. The piston is surrounded by a helical or spiral spring, which is compressed when the piston is forced forwards, and serves to restore the latter to its normal position upon the pressure being removed, when the conical base of the piston, or a portion thereof, enters the before-mentioned recess in the breech-plate and locks the breech-block. The striking piston is actuated in the following manner:—The patentee employs a lever, one end of which is hinged to or placed in the before-mentioned spindle or hinge pin in the rear of the breech-block, and across the breech chamber, the same being constructed with a bevelled face corresponding with and working on the upper portion of the conical base of the striking piston. This lever, upon the hammer being released, is struck thereby, and, pressing upon the conical base of the striking piston, forces the latter forward, thus percussing the centre of the cartridge head, and causing ignition of the ammunition. The hammer is provided with a projecting "nose," which latter, upon the gun being discharged, fits into a slot or hole formed in the breech-block, or in a piece of metal attached thereto, and which before discharge receives a stud or projection upon the transverse lever. Upon discharge taking place, the latter is depressed, and the "nose" of the hammer entering the before-mentioned slot or hole firmly holds the breech-block in the chamber, and prevents any possibility of the same being forced open by any explosive power which may be exerted thereon. In order to extract or remove the expended cartridge case after the discharge has taken place, he adopts the following arrangement:—A small barrel or tube is placed over the partially revolving spindle or hinge pin to which the breech-block is attached, such barrel or tube being free to move thereon, and having formed therein an oblique or inclined groove or slot in which a pin or stud fixed on the spindle works. The barrel or tube is furnished with a projection which acts as the draw cartridge or extractor. Upon the breech chamber being opened by the raising of the breech-block, the barrel or tube carrying the draw cartridge or extractor is by the partial revolution of the spindle or hinge pin, and the stud fixed thereto working in the groove or slot in the barrel or tube, caused to recede from that part of the barrel of the gun which receives the cartridge. When it is desired to use the gun, the cartridge is placed in the breech chamber, and moved forwards into the barrel, the rim of the cartridge head being pressed upon the extractor which is carried forward by the closing of the breech-block. The gun having been discharged, the breech-block is turned back by means of a thumb-piece attached thereto. The barrel or tube to which the draw cartridge or extractor is fixed is thereby actuated, and the cartridge case withdrawn, thus obviating the necessity of a separate movement for that purpose.—Patent completed.

3493 A. M. CLARK. *Improvements in orthopedic apparatus for the prevention and treatment of spinal diseases.* (A communication.) Dated December 7, 1867.

This apparatus consists of a kind of chair mounted on castors, in which a child may either sit or stand, and move in any direction. The shoulders are supported by arms so as to keep them raised without inconvenience, while the head is also supported by a ring and elastic network, which, without preventing any natural movements, at same time relieves the weak parts.—Patent abandoned.

3494 J. A. MUNN. *An improved weighing apparatus.* Dated December 7, 1867.

This invention relates to a weighing apparatus wherein flat springs are used in connection with a dial to measure the weight, and is more especially adapted for use in kitchens, grocers' shops, and other places where small articles or quantities of material are weighed. The invention consists, first, in the employment of a flat spring; or springs with edges concave, or so curved that they shall gradually decrease in width from the ends towards the centre, thereby ensuring the bending of the said springs in lengthened curves, and preventing their breaking off at the ends or points of suspension. Second, in the combination with the said flat spring or springs of adjustable short pieces for increasing or diminishing the length, and, consequently, the stiffness of the spring or springs, to make their action conform to that of the pointer on the dial, so that the latter shall indicate correctly. Thirdly, in the combination with the said flat springs and dial of a set screw for adjusting the rack to set the pointer on the said dial at the proper position, whereby any slight variation in the position in the pointer when at rest may be corrected.—Patent abandoned.

3495 E. KEIRBY. *Improvements in elastic packings for the pistons of steam engines and for other purposes, and in the machinery employed in the manufacture of such packings.* Dated December 9, 1867.

This invention is not described apart from the drawings. —Patent completed.

3496 W. H. COOKE. *Certain improvements in springs to be applied to doors, and for similar purposes.* Dated December 9, 1867.

This invention consists in applying to one end of the ordinary rod or wire a small wheel, the periphery being slotted, drilled, or ratchet toothed, into which slots, holes, or teeth a sliding plate or bolt is introduced, to retain and prevent the wheel yielding to the torsion of the spring and turning, the fitting supporting the end of the wire and wheel being so arranged that the retaining plate or bolt enters into or passes through it, so as to form a strong support for the end of the plate or bolt. Thus, by forming the extremity of the wire square, and applying a key, having previously removed the plate or bolt, the wire may be twisted to an extra degree than when originally fitted, and by replacing the plate the extra torsion remains; or the direction of the torsion may be reversed; or by removing the plate or bolt the wheel wire turns in the fitting without any torsion.—Patent abandoned.

3497 W. CLAPPERTON. *Improvements in machinery for shaping cask headings and similar articles.* Dated December 9, 1867.

This invention is not described apart from the drawings. —Patent completed.

3498 W. CLARK. *A new instrument for clipping or shearing horses or other animals, also applicable to other similar useful purposes.* Dated December 9, 1867.

This invention consists in the arrangement of two steel blades having cutting edges, one of which blades has a comb or series of prongs attached to its back surface arranged along and projecting beyond the cutting edge thereof, while the other blade is made to pass backwards and forwards over the front surface of the first-named blade in such a manner that the cutting edges of the two blades operate with a shearing action in front of the comb. —Patent completed.

3499 L. ROSE. *An improved mode of preserving vegetable juices.* Dated December 9, 1867.

Here the patentee prepares lime juice, lemon juice, and other vegetable juices or medicaments, by employing sulphurous gas, either free or combined (as, for instance, as a sulphite or bi-sulphite).—Patent completed.

3500 W. R. LAKE. *Improvements in excavating machines, more especially designed for making ditches and drains.* (A communication.) Dated December 9, 1876.

This invention consists, first, in so arranging the driver's seat that his weight shall counterbalance that of the plough whereby the earth is loosened. Second, in combining with a flanged wheel two revolving belts between which the earth is elevated when loosened by the plough. Third, in a mode of regulating the depth of the cut, and at the same time changing the seat of the plough point. Fourth, in the substitution of guides for the land sides in common use. Fifth, in a mode of regulating the delivery of the earth excavated. Sixth, in a device for raising the machinery in turning; and also in that for raising the entire machine except the wheels. Seventh, in the use of an adjustable shoe for finishing the ditch to receive drain tiles. Eight, in so constructing the frame that, by folding the same, the distance between the wheels may be made wider or narrower. Ninth, in a mode of suspending the ploughs and frames so as to permit the said ploughs to work at a constantly increasing depth below the surface of the earth. Tenth, in the attachment of the draught at whatever depth the plough may be working. Eleventh, in arranging the plough and the parts connected therewith so as to loosen the earth and throw it between the elevating belts. The machine is more expressly designed for making ditches and drains. Reference to the drawings is essential to a full description of the invention.—Patent completed.

3501 H. BESSEMER. *Improvements in the manufacture of fire-bricks, tiles, and solid or hollow fire-lumps, and in the manufacture of retorts, pipes, crucibles, or other hollow vessels or moulds required to resist a high degree of heat.* Dated December 9, 1867.

The patentee claims, first, the manufacture of fire bricks, tiles, and solid or hollow fire lumps, retorts, pipes, crucibles, and other hollow vessels or moulds required to resist heat, by moulding or forming such articles in granulated burned clay, or in a mixture of clay and other materials that have been previously subjected to a red heat, and causing such granulated materials to cohere by the employment of a soluble silicate acted on by chloride of calcium, in the manner described. Second, the manufacture of ornamental bricks, tiles, quarries, trusses, bases, vases, busts, figures, columns, capitals, bases, cornices, copings, tablets, finials, and other articles of a similiar character employed in building and architectural decorations, by moulding or forming such articles in granulated burned clay, or in a mixture of clay and other materials that have previously been subjected to a red heat, and causing such granulated materials to cohere by the employment of a soluble silicate acted on by chloride of calcium in the manner described.—Patent completed.

3502 C. MARTIN, W. BARRETT, and T. S. WEBB. *Improvements in the treatment and reduction of titaniferous iron ores, and in the manufacture of iron, and in the construction of furnaces to be employed therein.* Dated December 9, 1867.

This invention mainly relates to certain improvements in the treatment of ilmenite, iserine, and other titaniferous iron ores, whereby the same can be more efficiently reduced than by the processes previously adopted, and also to the construction of furnaces for such purposes. The blast furnace or cupola which is employed for the reduction of the ore should be charged in the ordinary manner, and in the order and approximate portions stated in the specification. The details of the invention are voluminous.—Patent abandoned.

3503 C. KERBY. *Improved apparatus for filtering liquids.* Dated December 10, 1867.

We cannot here give space to the details of this invention.—Patent abandoned.

PROVISIONAL PROTECTIONS.

Dated February 6, 1868.

400 G. Roper, Bank House, Aylsham, Norfolk. **An improved screw propeller.** (A communication.)

Dated February 14, 1868.

501 W. E. Gedge, Wellington-street, Strand. **A process having for object the separation of animal from vegetable substances in textile fabrics, rags, or any other material containing them.** (A communication.)

Dated February 20, 1868.

565 W. Weldon, Park Villa, West Hill, Highgate, Middlesex. **Improvements relating primarily to the manufacture of chlorine by means of regenerated oxides of manganese.**

Dated March 14, 1868.

874 J. Petrie, jun., Rochdale, machine maker. **Improvements in machinery for washing wool and other fibrous materials.**

Dated March 24, 1868.

988 G. B. Paterson, Arnold's-place, Francis-street, Walworth, Surrey, machinist. **Improvements in gas meter indexes.**

Dated April 11, 1868.

1215 E. Dubois and E. Casper, Cannon-street, City, merchants. **Improvements in wet gas meters.** (A communication.)

Dated April 18, 1868.

1273 J. E. F. Ludeke, New Cross-road. **Improvements in machinery for obtaining motive power.**

Dated April 24, 1868.

1348 J. Liddard, Birkenhead, Chester, engineer, and G. Buxton, engineer. **Improvements in rails and chairs of railways, and in the method of adapting railway chairs to rails.**

Dated May 6, 1868.

1487 F. T. Hall, Gray's Inn-square. **Improvements in the manufacture of railways and other like tickets to adapt the same as mediums for advertisements.** (A communication.)

Dated May 13, 1868.

1560 M. Seß, Old Broad-street, City, engineer. **Improvements in the method or means for preventing the corrosion or incrustation of marine and other boilers.**

Dated May 16, 1868.

1616 G. Smith, Coalville, Leicestershire. **Improvements in pressing and finishing hollowed or chambered bricks and blocks, either of plastic materials or powdered clay dust, for building purposes, and in the apparatus employed therefor.**

Dated May 19, 1868.

1634 D. Riddell, Glasgow. **Improvements in the manufacture of bread, biscuits, and other preparations from flour, also in the manufacture of flour to be used therefor.**

Dated May 23, 1868.

1695 E. Jones, Redcliffe-street, Bristol. **Improved shadowless lamps.** (A communication.)

Dated May 25, 1868.

1708 T. Craig, Carey-street, Lincoln's Inn. **Improvements in the means or apparatus for hanging and supporting windows, doors, shutters, and other such like movable fittings in houses, vehicles, steamboats, and other places or structures in which such fittings are used.**

1720 H. A. Dufrene, South-street, Finsbury, London. **Improvements in the construction of railway wheels, pistons, and other articles made of wrought iron.** (A communication.)

Digitized by Google

Dated May 26, 1868.

1724 J. Adams, Cork. Improvements in machinery for washing or cleansing casks or barrels.

1729 J. Morgan, Kidderminster, Worcestershire, manager of works. Improvements in apparatus for regulating the temperature of and ventilating hothouses, conservatories, and other rooms and buildings.

Dated May 28, 1868.

1752 J. Reidy, Doddington-grove, Kennington Park, Surrey. An improved pick or pickaxes for excavating, mining, and other purposes.

1753 H. and F. Bailey. East Retford, Nottinghamshire, gas engineers. An improvement in the manufacture of valves for the passage of air, water, or any other liquid or fluid.

1755 W. Dalziel, Deptford, Kent, brass founder. An improved combination of cock and valve for controlling the flow of water from constant supply pipes.

1757 T. Drake, Huddersfield. A machine or apparatus to be employed for receiving communications, orders, messages, and appointments.

1759 W. E. Newton, Chancery-lane. Improvements in horse rakes. (A communication.)

1761 T. Greenwood, Leeds, machinist. Improvements in machinery for assorting the fibres of dressed silk. (Partly a communication.)

1763 J. R. Hambling, Norwich-road, East Dereham, Norfolk. Improvements in thrashing machines.

Dated May 29, 1868.

1769 W. Maclean, Glasgow. A new or improved process to be used for producing or depicting designs on textile fabrics.

1771 J. Drabble, Hasland, Derbyshire, and J. S. Raworth, Manchester, engineer. Certain improvements in machinery for the manufacture of roll or twist tobacco.

1773 J. B. Gardner, Kendal, Westmoreland, tobacconist. An improved machine for sifting pulverized tobacco in the manufacture of snuff.

1775 J. Nuellens, Torquay, Devonshire, and M. Neuhaus, urrey-street, Strand. Improvements in portable apparatus for cooling wines or other liquids in bottles or other like receptacles.

1776 L. Hamel, Stoney-street, Nottingham. Improvements in instruments for clipping lace and other fabrics.

Dated May 30, 1868.

1779 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in machines for stitching or sewing the edges of button, eyelet, and other holes in cloth, leather, and other materials, and for stitching or sewing the edges of cloth, leather, and other materials generally. (A communication.)

1780 A. Smith, Glasgow, merchant. Improvements in apparatus for the manufacture of sugar. (A communication.)

1781 R. Luthy, Bolton, Lancashire, engineer. Improvements in the construction and mode of working hydrostatic presses and hydraulic machinery.

1782 T. Burrow and S. Keith, Glasgow. Improvements in weaving, and in the machinery or apparatus employed therefor.

1784 J. Harman, Portman-square, London. A new or improved drawing board for the purpose of stretching drawing paper.

1785 H. Hirzel, professor of chemistry, Leipzig, Saxony. Improvements in the production of inflammable gas, and in apparatus to be used therefor.

1786 N. D. Spartali, Liverpool, steam ship agent. Improved apparatus for consuming hydrocarbon oils in the furnaces of marine and other boilers.

1787 J. B. Harris, Edinburgh. Improvements in pumps for actuating the pulp in paper-making machines.

1789 R. Turner, Dublin, civil engineer. Improvements in the manufacture of umbrellas.

1790 T. Field, Lambeth, Surrey, engineer. Improved arrangements for manœuvring gunboats and other floating vessels.

1791 C. E. Brooman, Fleet-street, City, patent agent. Improvements in the manufacture of central-fire cartridges. (A communication.)

1792 Rev. O. Reynolds, Debach, Woodbridge, Suffolk, M.A. Improvements in apparatus for steam ploughing or cultivating.

1793 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in spirit levels. (A communication.)

Dated June 1, 1868.

1795 J. B. Farrar, Halifax, machine maker. Improvements in, or applicable to, machinery or apparatus for spinning or twisting fibrous substances.

1796 D. Jones, Church-street, Inverness, mechanical engineer. Improvements in furnaces and heating apparatus, having reference to the consumption or prevention of smoke.

1797 G. P. Reed, Boston, Suffolk, Massachusetts, U.S. Improvements in watches.

1798 R. W. Page, Park-walk, Chelsea, Middlesex. Improvements in the construction of hand garden engines and hydropults.

1799 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in the manufacture of alum and other aluminous compounds. (A communication.)

1800 C. H. Wells, New York, U.S. A new and improved mode of impregnating wood with oleaginous and saline matters. (A communication.)

Dated June 2, 1868.

1802 J. Tate, Bermondsey, Surrey, machine fitter. A new or improved method of manufacturing points for railways.

1805 J. Avery, Great Portland-street, Marylebone, Middlesex. An improvement in apparatus employed in raising and lowering Venetian blinds, and retaining them in position.

1807 G. A. H. Lillie, of the Junior United Service Club, St. James's. Improvements in street paving.

1809 W. E. Newton, Chancery-lane. Improvements in cans and other vessels for containing liquid and other substances. (A communication.)

1810 J. Law, Edinburgh, dental instrument maker. A new or improved instrument for drawing corks from bottles.

1811 L. Sterne, Great Queen-street, Westminster, engineer. Improvements in the manufacture of driving belts, bands, or straps.

1812 F. Schafer, Piccadilly, manufacturer. A new or improved apparatus for removing wax and dirt from the tops of corks in bottles, and the combination of such apparatus with an appliance for drawing the corks.

1813 F. Roe, Cambridge-terrace, Notting-hill, Middlesex An improvement in smoking pipes, which invention is also applicable to cigar holders.

Dated June 3, 1868.

1814 R. Soans, Stockton-on-Tees, Durham, commercial traveller. Improvements in machines for removing dirt and foreign matters from currants and other fruit, and for afterwards drying the fruit.

1816 J. H. Johnson, Lincoln's Inn-fields. Improvements in pipe joints. (A communication.)

1817 J. H. Johnson, Lincoln's Inn-fields. Improvements in railway trucks or vehicles. (A communication.)

1818 L. W. Wright, Brooklyn, New York, U.S.A. Improvements in meters for water and other liquids.

1819 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in the production of iodine. (A communication.)

1820 H. J. Crockett, Kent Villas, Grange-road, East Dalston, Middlesex. Improvements in Venetian blinds, part of which improvements is also applicable to roller blinds.

1823 E. Fairburn, Kirklees Mills, Mirfield, Yorkshire, card maker. Improvements in condensers for working wool or other fibrous substances.

1824 W. E. Everitt, Birmingham, manufacturer. An improvement or improvements in the manufacture of tubes for marine boilers, surface condensers, and other similar purposes.

Dated June 4, 1868.

1826 W. Rye, Low Moor Iron Works, Oldham, Lancashire. Improvements in apparatus for supplying fuel to steam boiler and other furnaces.

1827 D. Foster, Sheffield, engineer. Improvements in combining and casting various qualities of metal in the manufacture of anvils, top and bottom faces for hammers for drawing-out purposes, projectiles, and other articles.

1828 G. Hartley and P. Robertshaw, Bradford, Yorkshire. Improvements in the construction of steam boilers and generating apparatus in connection therewith.

1830 M. Rives, Rue St. Antoine, Paris, merchant. An improved ship's block.

1831 C. E. Brooman, Fleet-street, City, patent agent. Improvements in apparatus for the manufacture or production of carbonic oxide, hydrogen, and carbonated hydrogens. (A communication.)

1832 F. Schafer, Piccadilly, manufacturer. A new or improved appliance for holding a stick of sealing wax.

1833 C. E. Brooman, Fleet-street, City, patent agent. Improvements in the manufacture or transformation of iron and steel, and in apparatus employed therein. (A communication.)

1835 J. Ashton, Fleet-street, City. Improvements in horse shoes.

1836 J. Worth, card maker, and A. Barker, plumber, Rochdale, Lancashire. Improvements in covering rollers and clearers used in machinery for preparing and spinning fibrous materials.

1837 J. Petrie, jun., machine maker, and J. Fielden, engineer, Rochdale, Lancashire. Improvements in obtaining hydraulic motive power, which improvements are also applicable to the propulsion of vessels by jets or streams of water.

1838 N. Salamon, Ludgate-hill, City, sewing machine factor. An improved mode of mounting photographic and other pictures, patterns, and advertisements. (A communication.)

1839 W. Firth, Burley Wood, near Leeds. Improvements in deodorizing petroleum and other oils.

Dated June 5, 1868.

1841 M. Henry, Fleet-street, City. Improvements in converting basic phosphates of lime into soluble acid phosphates of lime, and in obtaining and utilising sulphate of lime. (A communication.)

1842 A. M. Clark, Chancery-lane. Improvements in combination locks. (A communication.)

1843 J. Page, Mott-street, Birmingham. Improvements in corkscrews.

1844 C. D. Abel, Southampton-buildings, Chancery-lane. A new or improved stopping motion for spinning machinery. (A communication.)

1847 T. C. Gregory, Glasgow. Improvements in and connected with springs to be applied to railway rolling stock and otherwise. (A communication.)

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated June 12, 1868.

1924 G. Davies, Serle-street, Lincoln's Inn. Improvements in cranes. (A communication.)

Dated June 13, 1868.

1943 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for hulling or scouring wheat and other grain. (A communication.)

Dated June 15, 1868.

1947 W. Leonard, Massachusetts, U.S. An improvement in horse collars.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," June 23, 1868.

431 W. Richardson. Machinery for the manufacture of combs to be used in carding engines.

436 J. A. Nicholson. Water-closets.

446 W. R. Lake. Machine for cleaning grain. (A communication.)

448 G. Jessop and B. Senior. Machinery for preparing wool.

456 T. Smith. Steam engine counters.

460 J. R. Stoney. Appliances for the consumption of smoke.

466 J. S. Williamson. Drying machinery.

468 W. T. Woolley. Fastenings for purses

478 S. B. Tucker. Cartridge boxes. (A communication.)

487 W. E Deverna. Fastener, applicable as a substitute for buckles.

496 H. A. Bonneville. Compound of aniline colours. (A communication.)

497 H. A. Bonneville. Moderator. or carcel lamps. (A communication.)

498 A. Lemasson. Construction of indicators for showing the distance travelled by cabs, &c.

501 W. E. Gedge. A process for the separation of animal from vegetable substances in textile fabrics. (A communication.)

503 G. V. Wisedill. Ring for keys.

508 D. Whittaker. Healds or heddles and other parts of looms.

511 E. Cottam. Breech-loading firearms.

514 J. Barlow. Carriages. (Partly a communication.)

525 J. Walker. Manufacture of ornamental tiles.

526 A. M. Dufilhol. Method of shoeing horses.

534 C. E. Brooman. Breech-loading firearms. (A communication.)

539 W. Weild. Process of treating sewing threads.

543 T. Beeley. Keirs.

544 B. Blezard. Machines for cleaning wheat.

548 E. W. Young. Construction of bridges.

578 L. M. Becker. Manner of indicating the position and supply of fire plugs.

600 S. Firth. Machinery for cutting coal.

603 R. Heathfield. Cut nails.

606 A. Stenger. Umbrellas.

620 J. Elce. Lubricating the spindles of machines for spinning and doubling.

646 J. Perrett. Bottles for feeding infants.

665 W. E. Newton. Pens and pen holders. (A communication.)

667 J. H. Bass. Double cans.

673 J. Livesey. Coupling locomotive carriage wheels.

686 C. Sanderson. Manufacture of iron and steel.

700 W. Barford and T. Perkins. Apparatus for raising and stacking straw.

716 H P. Reynoldson. Portfolios.

730 S. A. Bell and G. H. Higgins. Match boxes.

769 A. V. Newton. Apparatus for cultivating land. (A communication.)

815 W. H. Halsey. Process for making articles from hard rubber.

827 A. Bourdon. Looms for weaving.

845 F. Ryland. Manufacture of pulleys for suspending window frames.

1293 W. Gorse. Preparation of strips of iron and steel for the manufacture of flat-pointed cut nails.

1355 J. Bernard. Preparing and dressing ores.

1485 A. C. Henderson. Mode of manufacturing albumen. (A communication.)

1761 T. Greenwood. Machinery for assorting the fibres of dressed silk. (Partly a communication.)

1763 J. R. Hambling. Thrashing machines.

1775 J. Nuellens and M. Neuhaus. Portable apparatus for cooling wine.

1947 W. Leonard. Horse collars.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed June 19, 1868.

3635 C. G. Wilson	10 W. J. Fraser
3637 J. Davison	26 M. E. Roy and L. Prevett
3642 C. W. Lancaster	
3649 J. Dawkins	58 W. Avery
